Bituminous coal production in the central Pennsylvania field has been reduced approximately 35 per cent, because of a lack of demand for coal. Rather than demoralize the market by cutting prices, operators are closing down the mines temporarily. A little coal has been sold under the Government prices at $2.95, but it had already been mined and was loaded on cars awaiting shipment. Coal operators say the supply is long all over the country, especially in New England, where many of the large consumers have a stock on hand sufficient to last them from four to seven months. At tidewater points the demand has also suddenly dropped.

The outlook for both miner and operator in the central coal fields is becoming darker each day, and many miners will be out of employment. About ten days ago two operations in the Altoona section closed down, one at Woodland and the other at Kersey. Since that time the number has continued until at present it is estimated that fully 250 mines in the central territory are at a standstill. These are small mines, employing from ten to fifty men. Nine of the larger mines of the district have closed.

It is estimated that there were 400 wagon-loading mines in this section, and of that number comparatively few are working. In the vicinity of Phillipsburg production has fallen off alarmingly and the few mines now operating have only a few men at work. At Reynoldsville production is at a standstill, and at Kittanning many men have been discharged for lack of orders.

All of the large mines in Cambria County are working, but a score of the small ones have shut down completely and probably forty others are working only half time. These shutdowns are, in the main, due to the fact that only the best quality of coal is in demand, and that the small producer, who could sell any kind of coal before the war ended, has no market for his product at this time. The mild weather is also responsible for the falling off in production for the smaller mines throughout the state.

Uniontown, Penn.

Through a system of underground haulage the output of several mines of the H. C. Frick company is being taken out at the mouth of the Alice mine, near Charleroi, for transportation down the Monongahela River to the Clairton byproduct plant. The longest haul now made is over a distance of 2½ miles, but the system will be extended shortly to handle the output of the Colonials, covering a haul of approximately 4½ miles.

When the entire underground system is completed the longest haul will be in the neighborhood of eight miles. This plan eliminates haulage, openings at many plants, provides quicker transportation and means an immense saving in time, plant operation, labor and shipping.

The Frick company has not adopted the plan of a number of independents in observing "layoff" days. All plants are working six days a week, but the relaxing of the labor situation due to the return of soldiers and the suspension of the team-track mines has resulted in the elimination of extra shifts and overtime, which was used so extensively during the war in increasing production.

There was a drop of 35,000 tons in the output in the Connellsville region during the week ended Jan. 25, due principally to curtailed operations at the independent plants. A still further curtailment is presaged for the current week. The aggregate output was 604,331 tons, from which there was manufactured 276,416 tons of coke. Raw coal shipments aggregated 189,707 tons.

Charleston, W. Va.

More than two thirds of the production loss in the Pocahontas and Tug River districts was due to no market. New England buyers, it is said, are withholding orders in the hope that prices will decline and that is responsible for an accumulation of tidewater shipments. It is predicted by Pocahontas coal men that instead of Pocahontas prices being lower they will probably advance as soon as there is the slightest hardening of the market. Prices quoted for run of mine coal in the Pocahontas district range all the way from $2.35 to $3.

Production has been affected to some extent in the Fairmont region by the attitude of the railroads, which, it is claimed by producers, are determined to secure their supplies of fuel at lower prices than are now prevailing; and since much Fairmont coal is used for railroad fuel, this is said to be making some difference in the amount of coal sold in the region. Coal is no longer requisitioned for the railroads. The new difficulties which have arisen may assume equal importance to those in controversy when the question of assigned cars was paramount. Embargoes are now in effect in connection with shipments consigned to Staten Island and Arlington piers.

Market conditions in general are responsible for low production in the Kanawha region, where the output is far below normal. In fact, insofar as it is possible to tell, operations, generally speaking, are limited to about three days out of a week, and consequently overhead expense is running high. This in turn is effectually having a tendecy to make prices firm. Summer weather throughout the country has played an important part in holding down production in the Kanawha district.

Congestion is affecting operations in the New River district to as great an extent as it is elsewhere in the state. One result of congestion was seen in the district on Jan. 27, when the Shipping Board imposed an embargo on tidewater coal which may be in effect for several weeks. Operators hope to offset their inability to ship to the east by beginning the shipment of coal to the West within a week or so, now that there are no longer any zone restrictions.

Victoria, B. C.

The Government of the Province of British Columbia has announced that it will stand by the settlers of Vancouver Island who are claiming the coal rights in connection with the lands they occupy providing they can prove that such claims are based on sound premises. It will be recalled that the Dominion Government last year disallowed the Provincial Act, giving the settlers a further period in which to record their applications, this measure being termed "An Act to amend the Settlers' Rights Act, 1904." One of the objections taken by the Federal Administration is that such legislation proposes to authorize the alienation of rights which were conveyed by the Province to the Dominion and by the Dominion conveyed to the Esquimalt & Nanaimo Railway Co. in consideration of the latter constructing a railway on the Island.

Among other points advanced by the Provincial Government in its answer is that there is no difference in principle between the Act of 1917 and that of 1904, both being identical in character, and that the Dominion is inconsistent in disallowing the one and allowing the other to stand. This legislation, and the conflict which it has caused between the Federal and Provincial Administrations, involves title to considerable of the undeveloped coal areas of the Island. This is now, for the most part, in the hands of the Canadian Collieries (D) Ltd., to which company it was transferred by the Esquimalt & Nanaimo Ry. Co

Acting on instructions from Hon. William Sloan, Minister of Mines, the Chief Inspector of Mines of British Columbia has arranged for a series of practical tests of the efficiency of the Gibbs mine rescue apparatus and the Paul breathing apparatus. These began on Tuesday, Jan. 28, at the Government mine rescue station at Nanaimo and will continue until the efficiency of the machines is thoroughly demonstrated.

PENNSYLVANIA

Anthracite

Lykens—A number of miners were penned in the mines for several hours recently when a string of cars broke loose on the electric slope and dashed to the bottom, tearing out the props and letting loose about fifty tons of coal and rock.

Larksville—Responding to an advertisement of the Hudson Coal Co., carpenters by the dozen, with their tool chests, applied at the Plymouth No. 5 colliery the day after the big breaker burned, and every applicant was put to work. The intention is to push erection of the new breaker to completion with the utmost dispatch.

West Pittston—A cave-in which recently occurred on Elm St. is supposed to be due to the abandoned workings of the old Clear Spring mines. A considerable area was affected. No damage resulted, as no properties are located in the area disturbed. J. L. Cake, owner and manager of the colliery, was on the scene shortly afterward and had men filling in the hole with ashes

Bloomsburg—Representatives of the various coal companies operating in Columbia County met with the county commissioners on Jan. 28, regarding the assessment of coal lands. The commissioners, believing that the coal companies have not been paying a just tax because of the low valuation at which their land has been assessed, some time ago employed M. J. Flynn, a mining engineer, as an expert to assist them in fixing a proper valuation.

Upper Lehigh—The project started by the Anthracite Forest Fire Association to fight against forest fires in the hard coal region has the hearty support of the anthracite coal operators. This place was selected for a new lookout tower to be erected by the association on a site for which the M. S. Kemmerer Coal Co. has given full rights. Telephone communication enables prompt advice and location whenever a fire starts. The nearest tower to Upper Lehigh is located on Broad Mountain, south of Hudsondale colliery, and enables the guard on duty to see the surrounding country for miles. It is expected that more of these watch towers will be erected by the coal companies in various parts of the mining region.

Hazleton—"Broken time" has again come to the anthracite field, after nearly four years of steady, high-pressure production. Upper Lehigh and Hazle Brook, both Wentz collieries, will operate five days. Beaver Brook colliery of Dodson & Co. will work four days a week. Madeira Hill & Co., operating at Harleigh and in the Schuylkill region, will work three days. The Lehigh Valley Coal Co. went on a seven-hour a day schedule last week. G. B. Markle & Co., of Jeddo, will work full time, storing its surplus coal. The Lehigh and Wilkes-Barre has not curtailed its working time as yet. With the shorter time all repair work and overtime has been stopped. The Wentz companies have all employees on a strict eight-hour basis. Washery and culm bank operations are nearly all suspended, and stripping work and development is practically dead.

Bituminous

Clearfield—Three miners, all residents of this section, were killed on Jan. 29 when a pocket of gas in the Goodyear mine at Smoky Run exploded. The victims were blown into a pool of water by the force of the explosion. The bodies were recovered.

Uniontown—First steps toward the conquest of Cuban fuel markets by Fayette County coal and coke will shortly be made by a party of Uniontown coal men and bankers. Wilmer H. Wilkey, Jacob H. Linn, A. Plumer Austin, J. Edgar Hustead and Harold W. Semans, representative local fuel producers and capitalists, sailed from New York on Jan. 26 and will spend several weeks examining the Cuban market conditions with a view to exporting Fayette County coal and coke to the island. Other local interests are planning for the investigation of South America also.

Uniontown—Verdict of accidental death with no blame attached to W. J. Rainey was returned by the coroner's jury inquiring into the dealth of Samuel Hardy and William C. Foltz, miners, asphyxiated at the Mount Braddock mine Tuesday, Jan. 21, when a fire on a slate pile on the surface burned through to the working. The inquest was conducted by Mine Inspector Richard Maize, who commended highly the work of Mike Sostchech, Frank Krum and August Klaus, members of the Orient rescue team, who performed valiant rescue work.

WEST VIRGINIA

Gilmer—Parkersburg and Clarksburg people have acquired control of the Gilmer Fuel mine located at this place on the Coal & Coke Ry., this company having been owned and operated prior to this time by outside capitalists.

Cameron—Further information obtained in connection with the plans of the recently organized Dunkard Valley Coal Co. discloses the fact that a drift mine will be operated here by the company and that the estimated capacity of new work in tons per day will be 2500. No development work, however, has been started, but such work will be commenced soon. Equipment and material needed has not so far been ordered. The office of the company will be in Morgantown.

OHIO

Lima—The Lima Coal Co. will soon begin the work of opening a new mine near Charleston, W. Va. The mine has been projected for several months, but only recently was permission secured from the Railroad Administration to build the necessary switch. The mine will have a capacity of about 400 tons daily. It is located on the Coal & Coke Ry.

Chillicothe—A 6 ft. vein of good quality cannel coal has been discovered on the farm of Nelson Johnson, in Franklin township, Ross County. The extent of the vein is undetermined.

Pomeroy—At the annual meeting of Subdistrict No. 2 of District No. 6 of the United Mine Workers of America, George Cecil of Wellston was elected president; William Lamb of Jackson, vice president, and Henry F. Bartles of Minersville, secretary-treasurer. A new board was also elected.

INDIANA

Vincennes—About 30,000 lb. of mine powder and the brick house in which it was stored were burned in a fire of undetermined origin at the Oliphant-Johnson Coal Co. mine, at Bracewell near this city. Mine officers state that the loss cannot be estimated at this time. The fire was discovered about an hour before time for the men to enter the mine. The powder house was located a short distance from the fan-house, which supplies the mine with fresh air, and smoke blown into the mine made it impossible for the men to work. The dynamite building is located some distance from the powder-house site. Had the powder been of the explosive kind the disaster would have been much more serious.

ILLINOIS

Caseyville—The shaft of the Ruby mine here caved in a few days ago, throwing 75 men temporarily out of work.

Christopher—The Illinois Public Utilities Commission has approved an agreement of the Burlington R.R. with the Old Ben Coal Co. relating to the construction of a 33,000-volt electric power transmission line.

Danville — The Illinois Public Utilities Commission has approved an agreement with the Missionfield Coal Co., relating to the construction and maintenance of a 2300-volt electric power transmission line at Oakwood, Ill.

ARKANSAS

Hartford—The Central Coal and Coke Co. has installed a 7 ft. 6 in. x 5 ft. Sirocco fan at its No. 4 mine.

Foreign News

Sydney Mines, N. S.—President D. H. McDougall, of the Nova Scotia Steel and Coal Co., announces that the company will take advantage of the slack spell in steel production to overhaul its plant and make necessary repairs and additions. The cost of production at the collieries has been for some time past extremely high, rendering it impossible to compete in the general coal market and affecting the cost in iron and steel production. It is hoped to effect such improvements as will enable the company to resume its position in the coal market. The plans include the installation of new and thoroughly up-to-date byproduct coking ovens. The company also proposes to push development at the Wabana iron ore mines, in Newfoundland, so as to enable the production of iron ore much in excess of its former output at materially reduced costs.

Personals

H. C. Price has been transferred from the Ennis mines of the Turkey Gap Coal and Coke Co., to the superintendency of the mines at Dott, W. Va.

R. Q. Mahoney has resigned his position as mine foreman for the Turkey Gap Coal and Coke Co., Dott, W. Va., to engage in the automobile repair and supply business.

W. L. Honaker, who has been assisting W. C. Cooper with the engineering work in West Virginia, has accepted a position as mine engineer with the Superior Coal Co., Superior, W. Va.

William C. Moore, of Terre Haute, Ind., resigned Feb. 1 as assistant state mine inspector. Mr. Moore has served for the past three or four years, working chiefly in Vigo and Clay Counties.

D. H. Frazier, for the past seven years superintendent of the Turkey Gap Coal and Coke Co.'s mines at Dott, W. Va., has resigned and is now with the Mallory Coal Co., in Logan County, as general manager.

H. G. Happersett, until recently cashier of the Bank of Matoaka, Matoaka, W. Va., severed his connection with the bank and has accepted a position as superintendent of the Bradshaw Coal Co. Bradshaw, W. Va.

E. J. McKiernan, chief clerk at the Alliance Colliery of the Alliance Coal Co., has been promoted to the position of sales manager for the Alliance, Harewood and Cranberry Creek companies, with offices at West Hazleton, Penn.

John W. Smith is the new general superintendent of the Ingram Branch Coal Co. operating in Raleigh County. Before becoming associated with the Ingram company, Mr. Smith was the superintendent of the Alpha-Pocahontas Coal Co., at Alpoca, W. Va.

Edward H. Coxe, of Pittsburgh, Penn., has been appointed general manager of the Snowden Coke Co., to succeed Isaac Taylor, of Uniontown, who was recently elected president of the company. Mr. Coxe will be located at Brownsville, and have his office at Braznell, near Brownsville.

George Fraser has resigned the position of superintendent of the coal-mining operations at Cassidy's, Vancouver Island, of the Granby Consolidated Mining and Smelting Co. **George Hargreaves** also has resigned the position of mine manager. The duties of both the foregoing offices have been assumed by **R. R. Wilson**, formerly general superintendent of the Crow's Nest Pass Coal Co. Mr. Wilson is a son of W. R. Wilson, general manager of the Crow's Nest Pass Coal Company.

C. M. Moderwell has been appointed "Manager for the Receivers" of the O'Gara coal properties in Southern Illinois. The receivers are to be congratulated on their choice, as Mr. Moderwell is a man of very great experience in the coal industry, especially in Illinois. For a long time he was president of the United Coal Corporation, operating mines in the Franklin County district. When those mines were sold to the Old Ben Coal Corporation, he was connected with that concern in the capacity of vice president. Later on he resigned, and gave all his time to C. M. Moderwell & Co., a firm engaged in the jobbing business in Chicago.

Obituary

John B. Frost, superintendent of transportation for the Uniontown (Penn.) mines of the Oliver & Snyder Steel Co., died recently at his home at Uniontown. Mr. Frost had held that position for 18 years.

Joseph Earl Beury, one of the leading coal operators of the New River field of West Virginia, succumbed after a brief illness to an attack of influenza on Saturday, Jan. 25, at Turkey Knob, W. Va. Mr. Beury leaves a widow and five children.

William Ernest Minor, vice president and general manager of the Reliance Coal Co., Cincinnati, Ohio, died on Jan. 25 at Washington, D. C., of appendicitis, following an operation as the result of an attack which occurred as Mr. Minor was preparing for a hunting trip. Mr. Minor was widely known in the coal trade, with which he had been long and successfully connected. He was a Yale graduate of 1900, and was for a time connected with the Standard Oil Co. Mrs. Minor and four children survive him. He was 41 years of age.

Coming Meetings

Northern West Virginia Coal Operators' Association will meet at Fairmont, W. Va., Feb. 11. Secretary, F. J. Patton, Fairmont, W. Va.

Appalachian Coal Operators Association will meet at the Seelbach Hotel, Louisville, Ky., Feb. 14. Secretary, James E. McCoy, Knoxville, Tenn.

New England Coal Dealers' Association will hold its annual meeting March 19 and 20 at Worcester, Mass. Secretary, C. R. Elder, Boston, Mass.

National Foreign Trade Council will hold its sixth convention at the Congress Hotel, Chicago, Ill., April 24-26. Secretary, O. K. Davis, 1 Hanover Square, New York City.

Canadian Mining Institute will hold its annual meeting March 5-7 at the Windsor Hotel, Montreal, Canada. Secretary, H. Mortimer-Lamb, Drummond Building, Montreal, Canada.

American Institute of Mining Engineers will hold its 119th meeting Feb. 17-20, 1919, in the Engineering Societies' Building, New York City. Secretary, Bradley Stoughton, New York City.

American Institute of Electrical Engineers will hold its annual midwinter convention Feb. 19-21 at the Engineering Societies Building, New York City. Secretary, F. L. Hutchinson, New York City.

Stoker Driving Mechanism. M. Alpern, assignor to American Engineering Co., Philadelphia, Penn., 1,271,649, July 9, 1918. Filed Oct. 2, 1914. Serial No. 864,620.

Gas Producer Feeding Mechanism. C. W. Lummis, assignor to Morgan Construction Co., Worcester Mass., 1,270,962, July 2, 1918. Filed Mar. 10, 1916. Serial No. 83,396.

Means for Operating Overhead Valves of Coaling Apparatus. W. E. Hale, assignor to R. H. Beaumont Co., Philadelphia, Penn., 1,272,037, July 9, 1918. Filed Dec. 5, 1917. Serial No. 205,520.

Publications Received

Miners' Safety and Health Almanac for 1919. Compiled by R. C. Williams, Assistant Surgeon, United States Public Health Service. Miners' Circular 24. Department of the Interior, Bureau of Mines. Illustrated, pp. 48, 5⅜ x 9 inches.

Natural Gas: Its Production, Service and Conservation. By Samuel S. Wyer, of Columbus, Ohio. Smithsonian Institution, United States National Museum. Bulletin 102, Part 7. The Mineral Industries of the United States. Illustrated, pp. 67, 6¼ x 9¾ inches.

Trade Catalogs

Economy Drawing Tables and Sectional Filing Cases. Economy Drawing Table and Manufacturing Co., Adrian, Mich. Catalog N. Pp. 32, 7 x 10 in., illustrated. Sectional filing cases and specialties of a kindred nature.

Lakewood Clam Shell Buckets. Lakewood Engineering Co., Cleveland, Ohio. Bulletin No. 26. Pp. 24, 8½ x 11 in., illustrated. The principal features of the design and construction of Lakewood clam shell buckets are pictorially described.

Jacobsen Balanced Horizontal Screen and Picking Table. Jacobsen & Schraeder, Inc., Chicago, Ill. Bulletin. Pp. 4, 8½ x 11 in., illustrated. Describes the operation of the equipment and enumerates some of the advantages of the Jacobsen balanced shaker screen.

Sullivan "WA-5" Air Compressor. Sullivan Machinery Co., Chicago, Ill. Bulletin 75-D. Pp. 12, 6x9-in., illustrated. Describes a small, reliable steam-driven compressor built for standard pressures in capacities from 100 to 500 cu. ft. of free air per minute.

Fairmont Railroad Car Retarder. Fairmont Mining Machinery Co., Fairmont, W. Va. Bulletin No. 10. Pp. 4, 6 x 9 in.; illustrated. Describes a device for handling railroad cars under the tipple, the car being at all times under the control of one of the trimmers on the car. Possesses features of safety, economy and efficiency.

The Theory of the Storage Battery. General Lead Batteries Co., Newark, N. J. Technical Bulletin No. 28. Pp. 16 + cover; 6 x 9 in.; illustrated. Aims to give those who are interested in storage batteries and their construction an account of the recent improvements in manufacture, and to correct some erroneous ideas regarding their performance.

For Fuller Acquaintance. Beckwith Machinery Co., Pittsburgh, Penn. Circular. Pp. 12 + cover; 9½ x 12¾ in.; illustrated. Just what its title implies—information relative to the company's organization facilities in Pittsburgh. Interior and exterior views of the factory and warehouse are given, with a partial description of the machinery handled.

Industrial News

Indianapolis, Ind.—The Morris Coal Co. has increased its capitalization from $10,000 to $30,000.

Jasonville, Ind.—The Jasonville Fourth Vein Coal Co. has increased its capital stock from $10,000 to $40,000.

Freeburg, Ill.—The Mulbery Hill Coal Co., of this place, has increased its capital stock from $7,200 to $60,000.

Terre Haute, Ind.—The Glenjean Coal Co. has been incorporated with capital of $100,000, to engage in coal mining.

McArthur, Ohio—The Ferris Coal Mining Co. has been chartered with a capital of $25,000 by George L. Ferris and others.

Oakland, Cal.—The Merchant Calculating Machine Co. announces the opening of an Eastern sales office at 237 Railway Exchange Building, Chicago, Ill.

Toledo, Ohio—The Zanesville & Western Coal Co. has been chartered with a capital of $50,000 by I. W. Sharp, B. S. Brady, J. G. Backman, A. Cullen and H. A. Mullen.

Louisville, Ky.—The Louisville Coal and Coke Co. has filed notice of an increase in its capitalization from $15,000 to $25,000. to provide for general business expansion.

Indianapolis, Ind.—The Indiana and Eastern Coal Co. has been incorporated with capital of $25,000 to engage in the mining of coal. The incorporators are Edward A. Ogle, Ward H. Hackleman and Burrell Wright.

Raven Run, Penn.—The Raven Run Coal Co. has filed articles of incorporation with a capital of $1,000,000 to operate coal properties in the Raven Run district. H. B. Price, Philadelphia, is the principal incorporator.

Louisville, Ky.—The Louisville Coal and Coke Co. has filed amended articles of incorporation increasing its capital stock from $15,000 to $25,000. The amendment was signed by M. M. Kling, H. J. Kling and J. L. Eyl.

Terre Haute, Ind.—The Youngstown Coal Co. of Indiana, has been incorporated with capital of $10,000 to engage in coal mining. The incorporators are Arthur Shelburne Robert Orme, Albert Ferguson, A. J. Orme and Charles Baker.

Shelburn, Ind.—The Shelburn Coal and Mining Co. has been incorporated for $100,000, to mine and sell coal. August H. Skoglund, Carl S. Carlson, Leonard H. Skoglund, Ernest P. Nelson and Edward Hagelin are the incorporators.

Connellsville, Penn.—S. R. Goldsmith, of Connellsville, has acquired coal properties in Preston County, West Virginia, including plant for operation, and is arranging plans for the installation of additional machinery to increase the present capacity.

Buckhannon, W. Va.—F. E. Harne, of Cumberland, has been elected president of the Buckhannon Valley Coal Co., which will shortly begin development work at Sago, the company only recently having been organized with a capital of $20,000.

Peoria, Ill.—The Urbandale Coal Co., of East Peoria, has filed a certificate with the Illinois secretary of state of an increase in capital from $5000 to $50,000. The president of the company is Isaac Kommers, Jr., of Chicago, nad the secretary H. Schradzki, of Peoria.

Morgantown, W. Va.—The Chaplin-Keener-Kerr Co. has been incorporated with a capital of $25,000 to engage in the development of coal properties in the Grant district of Monongalia County. B. M. Chaplin, J. L. Keener and Raymond E. Kerr are the incorporators.

Fayetteville, W. Va.—Fayette County is to be the seat of operations of the Herndon Coal Co. just organized. About $100,000 is to be expended by the company on the construction of a plant. Charleston men interested are C. C. Lewis, L. C. Summerfield and Angus McDonald, and Fayettsville men are C. C. Herndon and James D. Boone.

Charleston, W. Va.—Mining operations in Boone County will be conducted by the Ashford Coal & Coke Co., made up largely of Charleston business men who have capitalized the new company at $25,000. The general offices of the company will be located in Charleston. The principal figures in the new company are J. L. Johnson, W. D. Holmes, George D. Cochrane, and R. A. Stewart, of Charleston; W. C. Delaney, of St. Albans.

St. Louis, Mo.—The municipal dock at the foot of North Market St. is nearing completion, and the first sailings of the St. Louis-New Orleans fleet will be from there. An electric crane has been installed and connections made with the railroad tracks. Loading of barges will begin in a few days It is expected that with the development of the river traffic quantities of coal which have heretofore gone by the rail routes will be handled by river.

New York, N. Y.—Nearly five million dollars, or to be exact $4,367,107.55, was disbursed in pensions by the United States Steel and Carnegie Pension Fund during 1918. Of this amount $215,021.59 went to pensioners attached to the various coal companies of the corporation, the H. C. Frick Coke Co. receiving $69,442.44; Hostetter Connellsville Coke Co., $1,041.60; United States Fuel Co., $137,400, and the Tennessee Coal, Iron and Railroad Co., $7,137.55.

Heiner, Ky.—Papers have been filed with the Secretary of State of Ohio increasing the authorized capital of the Daniel Boone Coal Co. from $325,000 to $575,000. The additional capital is to be used in taking care of the opening of a new mine, known as No. 3, at Heiner. This mine was put into operation soon after the first of the year and has a capacity of 1500 tons daily, making the total capacity of the three mines approximately 3500 tons daily. The mines are located on the Louisville & Nashville Railroad.

Cleveland, Ohio—On Sept. 17, 1918, the steamer "Col. James M. Schoonmaker," of the Shenango fleet established a new high record for coal. At Huron, Ohio, she took on a cargo of 14,767 net tons and 1100 lb. for delivery at Duluth, and thus displaced her record of 14,751 tons as made Sept. 26, 1917, by a little more than 16 tons. By this performance the "Schoonmaker" now has established her sixth coal record since 1913 and has gradually increased the high-water mark in this commodity by 1039 tons during the five years.

Nashville, Tenn.—The East Laurel Mining Co., 1 Arcade, has been incorporated with a capital of $50,000 to engage in general coal-mining operations at its properties near Gernt, Tenn. It is proposed to develop about 1800 acres for initial operations, to have a capacity of 500 tons daily. The company is arranging plans for the installation of the necessary machinery including tipple screens, air punches, slope hoist, mining cars and other apparatus. John P. Williams, Jr., is president-treasurer; J. P. Pearson is vice-president, and I. F. Ligon is secretary-manager.

Buffalo, N. Y.—Delaware & Hudson coal interests will again have direct representation here by the opening of an office at 1028 Prudential Building by J. B. McMurrich, the company's representative at Oswego. His son, K. D. McMurrich, Jr., will be in charge. When the office was discontinued in 1902, the Lake trade was dropped and the state and Canadian business was divided between McMurrich at Oswego and Millspaugh & Green, of Syracuse. Mr. McMurrich has long felt that in Buffalo he would be in closer touch with his Canadian trade than at Oswego.

Charleston, W. Va.—A coal-weighing bill similar to one introduced at the last session of the Legislature has been introduced in the House of Delegates by Representative G. R. Blizzard, of Fayette County. This bill provides in brief that every person and corporation operating a mine in which ten or more men are employed shall pay miners by weight and, therefore, that all operating concerns shall have duly tested scales at their plants, the county sealer of weights and measures being required to test the scales twice a year and oftener when occasion shall require it.

Kansas City, Mo.—The Consumers Coal and Mining Co. has been organized in Kansas City by J. M. Grodzins, president; J. J. Rooney, vice president; J. R. Barber, secretary, and A. H. Rapp, treasurer. The capital stock is $250,000. The mine is at La Cygne, Kan., and coal is now being shipped. The peculiar feature of the company is that it is advertising "a way to obtain cheap coal," that way being by purchasing stock in the company. A stockholder secures a reduction of 10 per cent. on cash transactions and 5 per cent. on charge accounts. A local firm has taken the exploiting of the proposition and is advertising it extensively. The La Cygne mine is expected to produce 200 tons a day.

Birmingham, Ala.—Adams, Rowe & Norman, Inc., have announced the opening of a coal and coke sales agency, Feb. 1, with offices located on the seventh floor of the Brown-Marx Building. The new firm is composed of three of the best known and most successful men connected with the trade in this district. W. C. Adams, for the past several years sales manager for the DeBardeleben Coal Co., is president; E. J. Rowe, sales manager of the Yolande Coal and Coke Co., is vice-president and secretary; and J. A. Norman, formerly of the Bonnyman-Norman Coal Co., is vice president and treasurer. These men will sever all other business connections and devote their entire attention to the activities of the new firm, having already contracted for the distribution of the output of mines.

Charleston, W. Va.—Under the terms of a bill introduced in the State Senate by Senator Lewis of Fayette County, it is made unlawful for any coal operator or his agent to employ any one but a sober engineer or drum runner in the operation of any hoisting or lowering machinery in connection with any mine worked by shaft, slope or incline. The bill also stipulates that such an engineer shall not permit any person, unless he be specially deputized, to interfere with the operation of machinery. Intimidation of the engineer or drum runner is also forbidden by the bill. Where a mine is operated by shaft or slope not more than ten persons are to be permitted to ride in a cage or car, and where a cage or car is loaded no one is to be permitted to ride on a cage or car. It is made mandatory upon the operator where ten or more men are employed under ground to have on hand a stretcher, woollen water-proof blanket and all necessary medical requisites.

Charleston, W. Va.—Under the terms of a bill introduced in the Senate of West Virginia by Senator Morton, of Webster, it is provided that whenever the mineral or other interests in or right appurtenant to land in this state have heretofore passed or shall hereafter pass in any way from a claimant in possession of the surface of the land, the continuity of the possession of mineral interests and rights shall not be deemed thereby to have been or to be broken, but the possession of the surface by the original claimant from whom such mineral interests or rights passed or by those claiming through or under him or by virtue of a judgment against him in an action to which the holder of said mineral interests or rights was not a party sha be deemed to have been and hereafter to be the possession of such mineral interests and rights in said land for the benefit of said person, his heirs and assigns to whom said mineral interests or rights have or shall have passed as already stated.

FOREIGN MARKETS AND EXPORT NEWS

Cut in Ocean Freight Rates

On Jan. 22 the Shipping Board announced a reduction in ocean freight rates over various routes, including some special rates on commodities to Belgium. This will afford an opportunity to American manufacturers to compete on even terms with foreign industries in the race for world trade. The British and French rates have already been lowered, and it was imperative that American rates be lowered to enable the expansion of the industries of this country. The American coal industry has reached greater productive capacity than ever before, and operators must seek an outlet for their product in foreign markets or else fall back on a plan of decided curtailment. The new rate for coal from American gulf ports to Chile is $16.50 a gross ton, while coal from Hampton Roads to the Hawaiian Islands is $20 a ton.

Great Britain's Coal Exports

During the war England was forced to abandon between 5,000,000 and 6,000,000 tons of her annual coal export of about 7,000,000 tons to South America. The United States increased its coal exports to Argentina, Brazil and Uruguay from 440,000 tons in the year ending June 30, 1914, to 1,619,000 tons for the year ending June 30, 1916. Something of the magnitude of the disorganization wrought in the British coal trade by the advent of the war may be perceived by a glance at the statistics dealing with the rush of mine workers to the colors when the war began. In the first year of the war 191,170 miners enlisted and in June, 1916, the total had risen to 285,000. On the latter date the net loss of mine labor had been reduced to 133,000 men through extraordinary efforts to return soldiers to the mines, but this program was interrupted early in 1918 by the necessity of returning 75,000 miners to the battle lines.

To	1913	1914	1915	1916	1917	1918 (To Nov. 30)
France	13,014,000	12,497,000	18,281,000	18,080,000	19,283,000	16,954,000
Italy	9,906,000	8,895,000	5,947,000	5,937,000	4,435,000	3,873,000
Norway	2,335,000	2,660,000	2,824,000	2,653,000	1,192,000	1,311,000
Sweden	4,837,000	4,533,000	2,749,000	1,674,000	622,000	1,010,000
Denmark	3,102,000	3,246,000	3,297,000	2,457,000	897,000	1,007,000
Holland	1,998,000	1,732,000	1,796,000	1,347,000	381,000	76,000
Spain	2,721,000	3,259,000	2,255,000	2,141,000	836,000	465,000
Portugal	1,358,000	1,068,000	926,000	803,000	254,000	141,000
Belgium	2,245,000	1,173,000	.....	.....	.....	.....
All others	35,173,000	22,767,000	7,695,000	5,566,000	9,991,000	7,090,000
Total exports	76,689,000	61,830,000	45,770,000	41,158,000	37,801,000	31,927,000
Consumed at home	210,741,000	203,834,000	207,436,000	215,217,000	210,672,000	176,800,000
Total production	287,430,000	265,664,000	233,206,000	256,375,000	248,473,000	208,727,000

The accompanying table (see above) gives the British coal exports for the past five years. The figures are in gross tons of 2240 lb. and include coal, coke and briquets. England's export restrictions, aside from keeping within the country the necessary quantity of coal for war operations, made an effective weapon in the conduct of the war, not only in assisting her allies, but in exacting favorable terms with neutrals.

Foreign Trade in 1918

The year just closed was a record maker in foreign trade, although exports fell a shade, 1.2 per cent, behind those of 1917. December exports were only three times exceeded in previous months and years, but the year's total, $6,150,000,000, while 12 per cent. larger than in 1916, dropped $76,000,000 below 1917. Imports for 1918, which totaled $3,031,000,000, were 2.6 per cent. larger than in 1917, but still were less than half the size of the exports. Total trade in merchandise in 1918, $9,181,000,000, exceeded 1917 by only about $3,000,000. Silver exports in 1918 broke all records, totalling $253,000,000, or three times those of 1917. Gold exports were only one-ninth those of 1917, the record year, while imports were only one-eleventh of those of 1916, the peak year in this respect.

Why Great Britain Dominates the World's Coal Markets

In the foreign commerce of England coal occupies an exceedingly important place. This can readily be realized when it is known that the value of the coal exported from the United Kingdom in 1913 was no less than 8½ per cent. of all the goods exported by England that year. In fact, the British overseas trade in coal is more than twice that of the whole of the rest of the world put together.

In seeking the causes of the astonishing growth of British exports of coal during the last half century, one finds that the increase is attributable first to the growth of the demand in Europe (due to industrial activity following the settling of political difficulties) and South America, and next to the improvement in the means of transportation.

England disposes of 87 per cent., or nearly the whole of her exports of coal, to the European and Mediterranean market, ports in Belgium and to the north of Belgium taking some 26 million gross tons; the French and Mediterranean ports (including North Africa) take 30 million gross tons; South America takes well over 4 million gross tons.

Great Britain's distant markets, as a whole, are comparatively unimportant to her except to one coal field—South Wales—because of the high freights required by long voyages; it is only the high quality of the Welsh steam coal which gives it the exceptional position it occupies in foreign markets. Physically the Welsh steam coals are semi-bituminous, quite hard and durable, and capable of standing shipment well.

Another thing that favors England is the fact that her two richest coal basins—those of Wales and Newcastle—are handy to tidewater. The average railroad haul of the Welsh coal produced for export is less than 50 miles. Contrast this with our long haul to shipping points! English coal owners can load and ship their product in the most economical manner and consign the cargoes to any point overseas. Ocean conveyance, too, is cheaper in English commerce because of the tremendous amount of raw and other material she imports in her returning vessels.

Foreign Freight Rates

W. W. Battie & Co.'s coal trade freight report for Jan. 27 states:

The scarcity of orders to the West Indies still continues, and naturally but a few charters are being effected. We have numerous boats asking for such business both prompt and February loading. The South American market is very dull, owing to the scarcity of tonnage. We would quote the Chartering Committee's rates as below:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 3000 tons dis.; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Guantanamo, $8.50, 500 tons fuegos, $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge.

Sail (maximum) — Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net; Santos, $19.50 net; Buenos Aires, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. (Gross rates $1.50 per ton in excess of net rates.) On all the foregoing rates, charterers pay vessel's towage to coal port. To Nitrate Range, $16.50 gross prepaid. (Same rate steam.)

The Chartering Committee's rate by steam is $19.50 net to Rio or Santos, $18.50 net to Buenos Aires and $19.50 net to Montevideo.

Markets in Which American Coal Can Compete

If the problem of ocean freights and adequate shipping facilities can be worked out satisfactorily, the markets given in the tabulation below would be thrown open to American coals on a competitive basis. The figures given are as of 1913, before the world war disturbed the established channels of trade, and they approximate the tonnages that are imported in normal times by the respective sections named.

	Gross Tons
Atlantic and Mediterranean ports	35,767,749
West coast of Africa	567,037
Asia, Pacific Islands and Australia	433,062
East and west coast of North America	189,332
East coast of South America	6,334,553
West coast of South America	605,345
Bunker coal	19,161,267
Total	63,058,345

It will be perceived from the table that were the United States to enjoy a complete monopoly of the world's coal markets it would amount to about 10 per cent. of our total annual production of bituminous coal. This monopoly, of course, is impossible; and to set our cap at the South American mar-

How the Government Will Help Solve Your Export Problems

COAL operators who are desirous of obtaining more definite information regarding the extensive plans of the Department of Commerce in relation to the expansion of our foreign trade can avail themselves of the vast fund of knowledge possessed by our own Government agencies. The possibilities of the application to industry of the organization created by Secretary William C. Redfield of the Department of Commerce is shown in the diagram. From reports of the various trade commissioners now returning to this country it is felt that the work of the Department should be of infinite value to those who are seeking foreign markets. Aside from the information given in the chart, there is being issued a monthly index on statistics pertaining to specific articles of import and export, as well as general information on markets for given products. Application for information regarding export business should be addressed to the Bureau of Foreign and Domestic Commerce, Washington, D. C.

kets alone would mean an outlet for little more than 1 per cent. of our annual output. Everything being equal, England's hold on the European market cannot be broken; but at the present time Great Britain is experiencing considerable difficulty with her coal miners, and her output has fallen off to an abnormal extent. Herein lies America's opportunity. Whether we succeed in retaining permanently the foreign markets that we will assuredly enter in the near future is problematical. There will be every advantage in England's favor when the world once again settles down to normal. In the event that we should succeed temporarily or permanently in entering foreign coal markets, it is a foregone conclusion that grades equal to New River and Pocahontas would enjoy the bulk of the export trade, as these coals not only possess characteristics that should find favor with foreign consumers, but they can be advantageously transported to tidewater. The State of West Virginia alone, with an output of more than 97,000,000 short tons of soft coal in 1918, could more than take care of the entire world's fuel markets.

Canadian Ocean Rates

The freight rate on steamships plying regularly between Canada and the British Isles has dropped to $1.50 a cubic foot, it was announced in Montreal on Jan. 23. Canadian shippers say that vessel space will soon be seeking cargoes, thus reversing the conditions which have prevailed for four years. The rate before the war was 30 cents a cubic foot.

Coal Shortage in England

To relieve the shortage Great Britain is turning attention to the potential coal resources of Ireland. Operations are about to be commenced in County Tyrone and borings will be made at Coalisland and in the district between there and Lough Neagh. Lignite abounds in the region and its utilization is to be undertaken at once. It is to be stripped from its bed by rotary cutters and made into briquets by a secret process, which is said to make lignite a good coal substitute. Machinery already installed will be capable of producing 15,000 tons of briquets weekly.

Coal Needs of France

Considerable discussion is prevalent in French circles as to the position of France with respect to her future coal supplies. The suggestion has been made that Germany should supply France with some millions of tons of coal, to be set off against indemnities and as compensation for the havoc wrought by Germany on French territory.

France, in normal times, imports about 23,000,000 tons of coal annually. In the future she expects to eliminate the necessity of importing coal by the exploitation of the coal beds which she will claim from Germany as being part of her own territory, and which she looks forward to as eventually coming within her own borders. Not only has France advanced the claim that Lorraine rightfully belongs to her, but she also states that the new boundaries should include the region of the Saar.

If France succeeds in gaining her demands, about 18,000,000 tons of the 23,000,000 tons she now imports annually would be available. This, in turn, would have a far-reaching effect on the coal trade of England, for France is Great Britain's largest customer for coal. It would seem that not only would the French market be considerably restricted so far as British coals are concerned, but that plans (or visions) of a large export of American coals to France will suffer quite some modification.

German Coal Situation

For the present the coal situation throughout Germany is so threatening that all other questions are overshadowed. The daily production in the Ruhr district is less than 10,000 tons, against 24,000 tons during the war and 33,000 tons in peace times. Upper Silesia is producing 2000 carloads daily, against 11,000 carloads in war times and 14,000 carloads under peace conditions. The reserve supplies of coal in the hands of consumers are virtually exhausted.

As a result of the coal shortage large factories in many German cities are already closed down, and it is thought that a number of the biggest plants in Berlin will have to suspend operations if the situation does not improve soon.

The lack of sufficient rolling stock to transport even the comparatively small quantity of coal being mined further aggravates the situation. Labor conditions, too, have served to complicate matters. A strike epidemic is prevalent in the coal districts, and it is impossible to get enough workers at the mines.

MARKET DEPARTMENT

Weekly Review

Bituminous Production Falling Off Through Lack of Demand—Prices Lowered on Some Grades of Soft Coal—Operators Investigate Foreign Markets—Anthracite Mines Curtail Operation—Impending Labor Troubles.

NO ONE seems to worry much about production statistics these days, though as a matter of record it should be stated that the output of soft coal has fallen considerably below current consumption. An overstocked market, poor weather conditions (from the operator's and dealer's viewpoint) and the elimination of all control by the Fuel Administration are a combination of demoralizing circumstances from which the coal industry can expect no immediate relief.

It is still too early to judge of the full effects an uncontrolled competitive market will have on coal prices. If the statements of a number of prominent bituminous operators can be taken to mean anything, however, the nation will witness the closing down of many mines sooner than a reduction in the price of coal that will force them to operate at a loss. This is not to be taken to mean that the last ruling Government maximums are being adhered to as standard. In fact, reports of cuts in prices and offerings at considerable reductions below former figures are common, though in the majority of cases this is true only of the medium- and low-grade coals.

In the hope that it will enable them to furnish an outlet for the full productive capacity of their mines, many soft coal operators are investigating the opportunities and possibilities afforded by foreign markets. England, to which the European continent and South America had formerly looked for their fuel supply, now finds itself hard put to it to meet her coal obligations. Labor troubles and a multiplicity of other social and political ailments have served to hamper British coal output to an abnormal extent; and it is not at all improbable that if the Federal Government comes to the aid of American coal producers by establishing ocean shipping rates that will enable successful competition with English shipping, the United States will gain a worthwhile hold on the foreign coal markets.

At home no improvement in the demand for soft coal is expected until well along in the spring. Even then much depends on the manner in which industry in general resumes activity. The railroads, the largest consumers of coal in the country, have stopped making requisitions on the mines, and the national association of bituminous operators has made concrete proposals to Director General Hines looking to a speedy settlement of the vexing question of railroad fuel prices. No decision has been made as yet, though Mr. Hines promises to devote his attention to the matter after he gets through with his hearings before the Interstate Commerce Committee of the Senate.

Operators, as a rule, are optimistic regarding the future, believing that once the political situation in Europe is cleared the long pent-up flood of orders for a vast quantity of material will be let loose, and that the United States will come in for a goodly part of the new world's business.

The anthracite end of the coal industry was surprised on Jan. 31 by Dr. Garfield's announcement that all prices and restrictions on hard coal were to be removed, effective Feb. 1. In concrete, this means that Government supervision of the entire coal industry is now a thing of the past. Control is unnecessary, for there is little if any demand for any grade of anthracite coal. It is becoming more and more difficult for the anthracite mines to dispose of their output. A number of collieries have shut down completely, while many others are working only three and four days a week. So listless is the demand for hard coal that the railroads have ceased the movement of coal trains on Sundays. Offerings of steam sizes of anthracite have been made at marked reductions from the so-called Government prices, but these have met with exceedingly little buying response.

To put the matter concisely, the market activity in both hard and soft coal is conspicuous by its absence, with a consequent slowing down of operation at the mines. That this will have a bad effect on mine labor is almost a foregone conclusion; already the murmurings of discontent grow louder and louder. Only the active resumption of industry on a large scale will ward off impending labor troubles in this country. Preachments and admonishments to sit still and "not rock the boat" are of no avail whatsoever. Only real, live tangible work will give employment to thousands now unemployed. When the country is busy, and then only, will our coal mines be called on to operate at top-notch efficiency.

WEEKLY COAL PRODUCTION

A considerable decrease occurred in production of bituminous coal during the week ended Jan. 25, the output declining to the low level of 9,159,000 net tons. This production, which falls approximately three quarters of a million net tons below the preceding week, and approximately one million net tons below the corresponding week of last year, is at the rate of 475,000,000 net tons per annum and is considerably below present consumption. Many consumers are now using coal accumulated during last summer and the present good weather enables certain consumers to await the outcome of the raising of the zone and price restrictions by the U. S. Fuel Administration before placing their orders.

The daily production of bituminous coal during the current week, estimated at 1,526,000 net tons, is below the daily average for the coal year to date and behind the daily average for the same period of last year. The total production for the period Apr. 1 to Jan. 25 is now estimated at 485,656,000 net tons and is 34,855,000 net tons in excess of last year's production for the same period.

The production of anthracite increased considerably during the week ended Jan. 25, and was slightly in excess of the average weekly production for the coal year to date. Preliminary estimates place production of anthracite for the current week at 1,886,000 net tons as against 1,786,000 net tons during the week of Jan. 18, and as against 1,719,000 net tons during the week of Jan. 25, 1918. The daily average during the current week, estimated at 314,000 net tons, is a slight increase over the daily average for the coal year to date, and but 3000 net tons behind the daily average for a similar period of last year.

Carriers' reports show a decrease in cars loaded in all districts compared with the preceding week, with the exception of Alabama, where the increase was slight. Material decreases occurred in western Pennsylvania (800 cars), in Ohio (2800 cars) and the district including Illinois, Indiana and Western Kentucky (5300 cars).

New England Shipments—Bituminous coal shipments to New England, during the wek ended Jan. 25, are estimated at 344,112 net tons, an increase of approximately 33,000 net tons, over the shipments of the week preceding. This improvement occurred entirely in the receipts through the rail gateways, the increase in this tonnage for the week amounting to approximately 44,000 net tons, over the week of Jan. 18. Tidewater shipments declined during the week approximately 11,000 net tons, and was brought about chiefly by the low tonnage loaded at Baltimore.

Tidewater Shipments—Shipments of bituminous coal from Atlantic harbors for the week ended Jan. 25 amounted to 683,994 net tons, and, as in the case of New England, tidewater shipments fell slightly below the performance of the week of Jan. 18. Shipments from New York and Philadelphia were in excess of the preceding week, while shipments from Baltimore and Hampton Roads fell considerably behind.

Beehive Coke—Production of beehive coke for the week ended Jan. 25 is estimated at 575,000 net tons, an increase of 18,000 net tons over the week preceding, and 75,000 net tons over the same week of 1918. The average production per working day for the current week is estimated at 96,000 net tons as compared with 83,000 net tons during the week of Jan. 25 of last year. The

operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production at 280,767 net tons of beehive coke and the operation of their plants at 74.6 per cent. of their full time as compared with 76 per cent. during the week of Jan. 18. Considerable improvement occurred in labor conditions during the week. The same operators produced 163,650 net tons of coal.

Byproduct Coke—Byproduct coke production in the United States for the week ended Jan. 25 is reported at 558,876 net tons as compared with 559,298 net tons during the week ended Jan. 18, and 366,208 net tons during the corresponding week of 1918. During the current week the ovens of the country were operated at 84.6 per cent. of their full time, operating conditions remaining approximately the same as the week preceding. Loss of capacity attributed to lack of market increased slightly in Massachusetts and Minnesota. In the former state approximately one-half of the capacity is now lost on account of this lack of business.

BUSINESS OPINIONS

The Iron Trade Review—The industry is being obliged to make further curtailment of operations to square itself with the light volume of buying. A canvass of the pig iron situation shows that at the present time thirty-nine active stacks with an estimated daily capacity of 15,000 to 20,000 tons, have been blown out or banked, most of these since Jan. 1. Mill activities are not far from 60 per cent. on the average. The best showing appears to be in plates, sheets and merchant mill products.

Bradstreet's—Wholesale and jobbing trade is still at a waiting stage. Retail trade is less active, and the industrial pace, particularly in textile and iron and steel lines, is slower. Even collections are rather more tardy, and the number of unemployed is officially reported larger, this being confirmed by the advices of reduced active mill, blast furnace, and mine capacity from a number of points, of old orders running out, and of munition works turning over capacity to peace lines.

Dry Goods Economist—From most sections of the country come reports of good business despite the unseasonable weather, a falling market and a probability of strikes in some centers. Retailers are steadily reducing stocks. As a rule they are buying a little more freely than of late, but conservatism is the rule, except where manufacturers guarantee to maintain their prices for a definite period. The attitude of labor in textile and garment manufacturing plants is probably the most disquieting feature of the week's business.

The Iron Age—Export inquiry is awakened by the sharp cuts given to ocean freight rates on both sides of the Atlantic. The disparity of British and American charges has not been materially reduced but the change is sufficient to cause concern abroad, particularly over the possibility of United States steel and iron being imported to the exclusion of the home product. Some thousand-ton lots of finished steel for England are now in storage here awaiting favorable vessel rates, and stocks there made at high costs are not yet liquidated. In open competition an American mill has sold tin plates to Japan. The British fixed price is $43 a ton higher than the Pittsburgh quotation, and a less freight differential is all that is necessary to throw the business to the United States on a price basis.

Atlantic Seaboard

BOSTON

No significant developments. Continued anxiety on part of shippers over tidewater situation. Coastwise movement extremely light, especially of steam grades. Increase all-rail due to high rates by water. Gas coals also show better receipts. Railroads taking clean-up shipments on old contracts. Operators try to induce buying, but market unresponsive. Several Hampton Roads shippers practically without orders. More steamers tied up. Railroad supply comes forward in barges from New York at lower rates. Boston retailers reduce steam prices. Anthracite receipts show increase all-rail. Cancellations now the order of the day. Current deliveries at retail much reduced.

Bituminous—The market is at a standstill. Removal by the fuel authorities of all restrictions as to price and movement seems to have no appreciable effect on the current situation. Certain of the higher grade coals from central Pennsylvania are still being sold in a very limited way at the recent Government figure, but the inferior grades on the other hand can hardly be disposed of as a gift. As low as $2.25 f.o.b. mines per net ton has been heard, but it is not believed that any considerable tonnage can be placed even on that low level. The attitude of interests here who control mines is to sell what the market will absorb at a fair figure and then shut down until conditions improve. It is of course true that a large number of small operators who were able to make shipments last year now find mining too expensive, and in this way a fairly considerable tonnage will be lost this season. From present indications, however, it will not be missed, for New England consumers are still loaded up to the risers with coal taken during the scare last season.

The wide differential between rail and water delivery throughout this territory continues a source of great anxiety, especially to shippers from the Southern ports. The present decline in prices of the Pennsylvania coals is all the more disturbing, and all hands seem powerless to provide a remedy. In Boston today, in what is normally a market almost exclusively for Hampton Roads coals, a large proportion of Pennsylvania coal is now being used, and bought through channels other than the regular retail distributors. This is purely because of the great difference of price, and it is in recognition of this situation that Boston retailers who deal in Pocahontas and New River have already reduced prices, in some cases $1 a ton. There have been rumors that the Railroad Administration would be asked to advance all-rail rates as a remedy, and strange as it may seem something may be carried through on this line. It is at least in line with current enconomic theory.

Receipts by water of all the steam grades are extremely light. Little coal is being shipped from Baltimore for this territory, and dumpings at the Virginia piers have also been reduced to a minimum. A large number of mines have been embargoed because of failure to dump coal at the shipping port, idle operations are increasing in number from week to week. Deliveries inland on contract are limited to only a few cars daily, even from points like Providence, Boston and Portland, and with high-grade Pennsylvania grades open to the few buyers who are in the market it is easy to seen why they are not enthusiastic over paying premiums of $2@$2.50 for Pocahontas and New River.

Strenuous efforts are still being made by operating interests to induce buying in New England, but steam users are likely to continue unresponsive for a long time to come. Talk about possible labor difficulties and shutdowns fails to budge them, and with all the textile mills practically on a five-hour daily basis, it can readily be seen that present stocks will serve for a good many weeks beyond what was estimated last fall.

There are several Hampton Roads agencies that are practically without orders. Groups of mines are shut down until coal now accumulated at the Norfolk and Newport News piers is moved. Prices have shaded quite radically, one quotation being rumored at $2.25 for New River as compared with $2.70, the recent maximum. One or two shippers are venturesome enough to send coal forward "on the market," but recent experiences are not at all encouraging. Conferences are being held, but no solution has yet been reported.

The number of steamers tied up because of the lack of orders is steadily increasing. Steam colliers supplied to shippers in place of bottoms requisitioned last year for overseas are also being tied up at the expense of the party holding the charter, and meanwhile the Shipping Board gives no intimation of a possible change in rates. The ocean freighting situation has been somewhat cleared up during the week, but no further announcement has been made of any interest to coastwise shippers. One of the sidelights on this peculiar situation is the extent to which railroad-owned barge transportation is being used to freight railroad fuel to the eastern railroads. At current rates this transportation costs the railroads something like $1 less per ton than Shipping Board steamers, aside from the heavy demurrage clauses that apply to the latter, and a considerable tonnage has come forward in this way that would otherwise be freighted in steamers.

The Boston retail dealers reduced the price of bituminous in teams to $9.25 per net ton, this being a drop of $1 from the price that prevailed all winter.

Anthracite—Receipts of domestic sizes continue to show an increase all-rail. For the last eight days of January the average daily movement was 511 cars, a figure that had not been reached for some months. By water, too, shipments are in much better volume. Recent cargoes show an increasing proportion of stove and chestnut, now that the demand for these sizes is easing up from the big city markets.

Retail demand throughout New England is much reduced. In many cases deliveries to consumers were only about one-third of what had been estimated for January, and, as has so often been the case, just at the time when the shippers are in position to furnish what the trade has been howling for during the months past, orders are melting away like snow in July. Cancellations are now the order of the day in every direction, and we are in for a dull spell in anthracite as well as in bituminous.

NEW YORK

Removal of restrictions fails to affect local market. Plenty of coal available. Demand slow and dealers are not willing to place new orders. Independent coals quoted below company schedule. Anthracite steam coals in oversupply. Bituminous in good supply with demand slow and prices easy. New demurrage rules go into effect. Bunkering slow due to diversion of vessels to other ports. No immediate improvement expected.

Anthracite—Receipts of domestic sizes strictions on maximum prices of anthracite had little effect on the local situation. The announcement, which came as a surprise, had been anticipated for the past few weeks, but it was thought it would not be forthcoming until the middle of February at the earliest. Coming as it did at a time when coal is plentiful and demand slow, it did not affect market conditions.

The trade has been marking time. Weather conditions during January were anything but suitable for a heavy consumption of coal. Its accumulation has been such that producers and distributors have been receiving nearly as many cancellations as new orders, and consequently shipments from the local tidewater docks have been slow. Deliveries to inland dealers have improved considerably, these dealers having much better facilities for storing coal than the New York dealer has. These conditions are reflected in the report of cars dumped here during the week ended Jan. 31. For that period 4569 cars of anthracite were dumped as compared with 6558 cars the previous week, a decrease of 1989 cars. During the first month of the year 23,756 cars were dumped as compared with 26,261 cars in December, a decrease of 2505 cars.

The lack of demand is reflected in production, many of the mines being idle, and others having their working hours reduced. Reports received here are to the effect that most producers are storing the smaller sizes.

There is no desire on the part of dealers here to stock up. Most all have their coal pockets filled, and even with cold weather would have enough to meet all requirements for several weeks. Instead of the buyer seeking the seller conditions are the reverse, and in some instances inducements have been offered to move the coal. Quotations show many variations. Independent product has for several weeks been quoted at company or lower prices. All domestic sizes, including pea coal, are plentiful.

The steam sizes are on the toboggan. Little headway is being made to reduce stocks, and considerable storing is being done. Buyers are being favored with heavy concessions, but there is no demand.

Dr. Garfield's order resulted in a reduction in the retail prices of coal in Manhattan and the Bronx. Domestic coals, including pea coal, were reduced an average of 25c. per ton and steam sizes 35c. per ton, the change taking effect Feb. 3.

Delos W. Cooke, State Fuel Administrator, issued an order that the removal of the restrictions did not affect the regulations governing the sale and distribution of coal in less than half-ton lots in the City and State of New York, and that for the rest of the winter the price of coal in less than half-ton lots shall not exceed 60c. a hundred pounds at the cellar, when called for, and 70c. when delivered. Wagon venders and other peddlers must sell at the same prices. At retail dealers' yards the price is 55c. a hundred pounds on the cash-and-carry basis. In all other parts of the state existing rules as to the price and distribution of coal in less than half-ton lots shall continue in force until further orders.

Current quotations, per gross ton, f.o.b. Tidewater, at the lower ports are as follows:

	Circular	Individual
Broken	$7.80	$8.55
Egg	7.70	8.45
Stove	7.95	8.70
Chestnut	8.05	8.80
Pea	6.55	7.30
Buck	5.10@6.05	5.90@6.25
Rice	4.65	5.10
Barley	4.15	4.30
Boiler	4.60	

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—No immediate change in local conditions is anticipated as a result of the suspension of price and zone regulations on Feb. 1. The trade was notified on Jan. 17 that the Government would relinquish supervision of the industry, and it was prepared to adjust itself to the new conditions should it have been necessary. For several weeks past it has been well nigh impossible to obtain the Government maximum prices for almost any grade of coal unless it was of the very highest quality, and the fair and cheaper grades have been offered at prices considerably below the Government figure.

The situation has resolved itself into one of supply and demand. Conditions have not been favorable for coal consumption and most manufacturers are well stocked. In addition most textile factories have cut down their hours of operation, which in itself has considerably lessened consumption.

Operators and shippers are striving to land orders for immediate delivery, but their success is small. Consumers in the main are filled up and nothing save big inducements could make them add to their stocks. Indeed indications are that notwithstanding predictions of increased prices for certain grades it will be possible to buy at lower prices than present quotations before May 1. Hardly any shipper expects improvement before June 1.

Bunkering of vessels has slowed up due in part to the diverting of many bottoms to other ports. This has caused an easing in prices for high-grade coals.

Little attention is being paid to the making of contracts. As most of the consumers expect cheaper coal in the spring they are not anxious to sign up for next year's supply at anything like the present quotations. Some selling agents believe that contracts will not be signed up until June.

The new method of apportioning demurrage charges went into effect on Feb. 1. This method contemplates the charging of demurrage against those shippers to the pools on whose coals the charges have accrued after giving them the benefits of credits earned by those who have moved their coal in less than the free time.

The dumpings of bituminous coal at the local tidewater docks for the week ended Jan. 31 were 6187 cars as compared with 6103 cars the previous week, a decrease of 84 cars. For the month of January the dumpings amounted to 23,769 cars as compared with 25,169 cars in December, a decrease of 1400 cars.

Current quotations, based on Government prices at the mines, per net ton f.o.b. tidewater, at the lower ports, are as follows:

	Mine, Gross	F.o.b. N. Y., Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

No improvement in market conditions. All dealers carrying comfortable stocks of all the domestic sizes. Shippers continue to receive requests to suspend shipments. Practically no egg and pea coming here. Some individual coal being offered at company circular with few buyers. Steam sizes weak and causing much concern.

Anthracite—Conditions in both the wholesale and retail trade do not improve as the season advances, because the unseasonable weather does not warrant the forcing of fires for the consumption of family sizes. Owing to the unsettled condition of many of the industries, the steam coal market is demoralized, due to overproduction and the large stocks on hand.

The yards are comfortably fixed, and the dealers cannot believe they will not be emptied before spring. They are now ignoring the unfilled orders on their books, and are only making the deliveries when called upon. It is a satisfaction to note that so far they are holding the domestic market together, and while they are doing considerable advertising are not cutting prices. It will be remembered that their present gross margin of profit was not granted them by Mr. Lewis until he had the books of all the representative dealers examined by expert accountants. To cut into this now would not only be a reflection on the office of the local fuel administration, but would show that the dealers were insincere when they claimed they could not remain in business unless it was granted them.

It is plain that the individual operators are in a far more serious quandary than the dealers they supply. After the successful fights they waged in Washington to obtain, and retain, the differential allowed them by Dr. Garfield, it is not to be supposed they can now gracefully absorb it, even if their mining expenses warrant it.

We have it, however, on high authority, that there is some price-cutting among the smaller operators. At this writing, the practice is not at all general, and we are satisfied that where prices have been reduced it has brought little or no new business. The largest buyers in the city report having bought no coal from the individuals at company circular, and insinuate, that prices being equal, the big companies will receive the orders for any coal they may require between now and spring.

Restriction of production seems to be the only solution. The dealers have been paying their bills promptly because they have been quickly turning their coal into cash. Now, to persuade the trade to buy, when they are selling little, is to encourage longer credits. The retailers freely admit that where they are asking their customers to store more coal they are not receiving the money for it. It would not take long to have the buyer and the seller drop back into old habits, and this the wiser heads are anxious to avoid.

Shippers report that more dealers held their orders this week. By now there is practically no egg and little pea coal coming here. Whatever business remains is on stove and chestnut, but there are few yards without a supply of all sizes. Several dealers report selling horses this week, at a sacrifice by the way, and while in other years they have always dreaded snow, we have heard several express the wish for any change in the weather that will bring business.

The steam sizes show no improvement whatever, and we hear of buckwheat being offered around $3. There seems almost no demand for the smaller sizes, and the prices are correspondingly low. The companies continue to stock these small sizes.

BALTIMORE

Coal trade, back on a strictly competitive basis, finds new problems. Oversupply of soft coal here. Anthracite easy and demand light.

Bituminous—Many new problems—or old before-the-war problems in new dress—are facing the coal trade here in these days when the removal of Government restrictions has thrown business back on a strictly competitive basis. In the first place there is an oversupply of soft coal in this territory. Some hope is held out for the ready absorption of that part of the coal that can be classed as of better grade; but there is a tough road ahead for the other kind.

The demand that exists now is discriminatory. Jobbers, urged by mine connections, are working hard to convince consumers that now is a favorable purchasing season. This move, it must be admitted, has not been universally successful. Meanwhile there come reports of additional mine closings to await a more favorable market. Some mining sections have entered into a sharp competition.

Some days ago there were reports that Fairmont ¾ in. was offering as low as $2.40 to $2.50, as against the old Government maximum of $2.75, with little or no call at all for run-of-mine, which was a quarter less under the late Government figures. Freeport coals were also quoted as low, although the general run was a little better, a decided cut from the old figure of $2.75 as set by the Government. Then Pennsylvania coals entered into active competition, and in some cases fuels that had held at $2.95 maximum were offered at $2.75 and, in fact, less at times. These figures were too near production cost or below, and did not suit some operations, which have closed as a result. The trade feels that the congested market will gradually clear up and that then a better price will be maintained.

Anthracite—The demand remains light for anthracite in the face of the unseasonably warm weather. Dealers will be a little cautious in purchasing between now and spring, with cash costs undoubtedly at maximum. Few are willing to run the risk of being caught with any considerable reserves should a cut come in the wholesale rate. The supply here at present is more than adequate, and the only complaint heard is in regard to the light run of chestnut.

Lake Markets

PITTSBURGH

Sharp curtailment in production. Advanced prices announced. Coöperation of miners.

On the occasion of the relinquishment of price control by the Fuel Administration Pittsburgh district coal operators put out the following prices: Slack, $2.35; mine-run, $2.50; ¾-in., $2.60; 1¼-in., $2.75, per net ton at mine, Pittsburgh district. Government prices, which expired Jan. 31, were: Slack, $2.10; mine-run, $2.35; screened, $2.60. Thus mine-run is advanced 15c. A fact of prime importance is that about 70 per cent. of the mine capacity of the district is shut down. That is the form of expression, rather than that the capacity is merely idle.

On behalf of the operators it is asserted that some have been producing coal at a loss, selling at Government limits, and that under Fuel Administration regulations the Pittspurgh district was given a lower price, relative to cost of production, than almost any other coal-producing district in the country. It is asserted that some districts were given prices that were notoriously high, simply for the purpose of stimulating production, while the Pittsburgh district did not need, or at least was not active, in demanding at Washington, such an incentive.

Close relations are stated to exist between operators and miners in the district. The miners have large funds, which in an emergency they could use against the operators in a contest against wage reduction, but which they are quite ready to use in coöperation with the operators in an effort to secure a good price for coal, with such mine idleness meanwhile as is necessary to produce the desired results.

The market is not fully developed as yet, but it appears that standard grades of gas coal are selling at the adopted prices, as noted above. As to steam coal, there is no demand, and it is said that there are no sales of importance at lower prices, though cuts to the former Government price of $2.35 for mine-run may easily occur. For the time being the market seems quotable at the announced prices, based on $2.50 for mine-run, and gas coal may be regarded as steady at that figure.

BUFFALO

Market still exceedingly dull. Not much prospect of early improvement. Mines shutting down to reduce surplus. More anthracite as weather remains mild.

Bituminous—The dullness continues. Consumers will not buy to any great extent, for they have large supplies on hand. A Buffalo jobber sent out a salesman lately to sound the trade, but every card report sent in noted large stocks everywhere. Not a consumer visited was in need of coal, and nobody would buy.

At the same time the feeling, at least so far as the operators are concerned, is more confident than it was, for they believe they can reduce production enough to hold the prices substantially where they are. Occasionally a cut price comes in, but it is declared that the Pittsburgh price is absolutely firm and can be held after the Government control is dropped. There has been more doubt as to the chances of holding the Allegheny Valley price, for the price is not only higher, but the coal is hardly as popular as Pittsburgh and cannot be used as generally as a rule. The jobber with no close mining connection is hit hardest, for he will get no concession and his ability to find consumers who need coal is small.

Anthracite—The mild weather has added another snowless and almost frostless week, which means that anthracite is in greater

supply than the demand. Some distributors say that a sudden cold snap would be likely to send every consumer with a small supply looking for an immediate filling of his order, but no one is afraid.

The prospect of a surplus of anthracite is so good that shippers have in one or two cases made some inquiries about lake tonnage; but they have gone no further. They say that if the winter continues mild another month they will have coal to load into vessels, and maybe before that, but nobody really looks for a frostless February.

Reports from Canada agree that the surplus of all sorts of fuel except anthracite is still large, and it may turn out that there is enough of that, in which case the dealers will have a large quantity of miscellaneous stuff to carry over, for the demand for bituminous is smaller than it is here.

CLEVELAND

No. 8 operators are showing more backbone and conversationally, at least, are adhering to Government prices. The tearing down of Government barriers has not yet affected the market, though many expressions are heard that price reductions all around are inevitable not later than Apr. 1. Lake coal shippers have agreed with upper dockmen that the Great Lakes coal pool must be abandoned, and are seeking the Railroad Administration's aid in making this possible.

Bituminous—With the closing down of more mines in southern and eastern Ohio, the surplus of bituminous has become less apparent. Consequently, operators are talking once more of the proposition that price cutting will not serve to increase demand, hence the futility of asking less than the Government price. Such talk, however, is confined to the larger operators, who are well backed by contracts. Scarcely a day passes that a job lot is not offered at a marked concession to move it in a hurry, to keep a step ahead of car service, or that some No. 8 operator is not willing to let go of a small tonnage for 25c. or so under the maximum. All that is necessary to buy steam coal under the Government maximums is to "shop" for it.

One peculiarity of the present situation is that there is next to no demand for slack, making the coarser grades scarce in proportion. Usually, the reverse is the situation. Retail dealers especially are being besieged with "bargain lots," which, however, the larger dealers seem averse to taking on because of the difficulty of explaining the old price when the job lot has been disposed of. The steam coal market is feeling no effects of the dropping of all Government restrictions. The retail market is expected to be shaken up about the middle of February, when shipments of Pocahontas are due. The coming of cold weather has not spurred the retail market greatly, while more and more industrials are tapering off operations. The net result is that the bituminous market daily is becoming more slack. Only the feeling that they should preserve an optimistic outlook prevents the larger operators from using the adjective "stagnant" in its fullest force.

Anthracite—Dealers continue to compete for anthracite business. Some of the larger retailers are long on furnace grades, which seem much more plentiful than stove sizes. Anthracite shipments continue to increase, but demand is stationary because of the absence of real winter weather.

Lake Trade—As forecast, the final word concerning the Great Lakes coal pool, which in the 1918 season was conducted by the Ore and Coal Exchange, Cleveland, of which Herman M. Griggs was manager, is to be said by the United States Railroad Administration. Meeting in Cleveland, upper lake dock operators and lake shippers agreed that the pool, must not be continued in 1919. From an operating standpoint the pool has proved 100 per cent., but the mixing of coals is too great an evil to be tolerated again—was the unanimous opinion. Individual sales and shipping should be restored at the earliest moment possible, was the sense of resolutions adopted. The one stumbling block is excessive demurrage. Formerly, shippers were granted 5 days' free time at lower lake docks, with demurrage $1 a day thereafter. Now, however, only 3 days' free time is allowed, and the demurrage beginning with the fourth day is $3 a day.

DETROIT

Termination of zone rules and Government price control of bituminous coal creates a rather unsettled market, with fear that some operators may make Detroit a dumping ground.

Bituminous—With heavy stocks of bituminous coal in reserve piles of most of the large steam plants, and filling the storage yards of the greater number of retail dealers, the ending of the Federal Fuel Administration's zone restrictions and removal of Government price control are productive of considerable uncertainty among the coal trade in Detroit. There is a feeling, however, among jobbers and wholesalers that the restoration of an open market on bituminous is not likely to be productive of any immediate increase in their volume of sales in Detroit. Some of the jobbers anticipate that the lifting of the zone rules will enable them to move considerable coal into points in Indiana, which were inaccessible under the Government limitations.

Among the retail dealers there is just now more of a desire to cut down present stocks than to bring more coal into Detroit. Their attitude is caused by the fact that a large proportion of the stock on hand is of low quality, and a good deal of it in the shape of mine-run or other forms of bituminous that are not regarded as desirable fuel for household use. The coal was purchased by the retailers when predictions of an impending shortage were being circulated, followed by bulletins from the Fuel Administration urging that any coal be taken to assure an adequate supply for household consumers.

With the better grade of coal from West Virginia and Ohio mines now to be had, there is some anxiety lest operators in those districts, in their eagerness to sell coal, use Detroit as the dumping place for speculative consignments. Such shipments coming into competition with the stock already here, it is feared, might produce disastrous results for many of the retailers, who, because of the unusually mild weather this winter have made little progress in clearing their yards.

Anthracite—Not much anthracite is being received, and some of the dealers are not putting forth very strong efforts to increase the supply as they realize that customers who are now being supplied with bituminous likely would insist on getting anthracite. The plentiful supply of coke is taking the place of anthracite with many householders.

COLUMBUS

Weakness still characterizes the coal trade in Ohio. Warm weather is retarding domestic demand, while steam demand is held down by extra large stocks in reserve. Prices are cut to a certain extent.

The coal trade is still weak. The continued warm weather has caused a lull in domestic demand. In fact it now appears that much coal will be carried over by householders, and that will affect the trade next summer and fall. Another point brought out is the fact that many consumers stocked up on an inferior grade of coal, which is causing some trouble. Thus consumers will be slow to buy until rather late in the season. Retail prices are pretty generally maintained, as dealers are still selling high-priced coal. Some instances of cutting are reported, but these are not sufficient to demoralize the market. Pocahontas is still in good demand, but other grades are not wanted in large quantities. Retail stocks are still large. The lifting of the zone restriction will mean a general movement of Pocahontas to northern Ohio points, from which section it was held away by Government restrictions.

The steam business is dull. Stocks are still large, and since large consumers are rather slow in getting on a peace basis, there is little demand expected before April. Rubber plants are well supplied, and the same is true of iron and steel factories. Public institutions have sufficient tonnage for some time to come. Purchasing agents are following the policy of waiting until their stocks are consumed. Railroads are only buying a small percentage of former requisitions and are still bearing down prices wherever possible. Many mines producing steam grades exclusively have been closed down indefinitely.

CINCINNATI

Demand remains dull in all departments of the market. Removal of zoning restrictions will not immediately stimulate business, as shipments West are not regarded as advisable.

There has been no change in the state of the market during the past week or so, and there is at present no indication that there will be any change for some time to come. The dominating factor in the situation remains the fact that coal in storage is of much larger volume than usual, and with the winter nearing its end and comparatively mild weather the rule all through the Middle West, prospects of any considerable amount of consumption in the remaining weeks of the winter are not bright.

The removal of the zoning restrictions, heretofore confining West Virginia and Kentucky coal marketed through this point to a field much more narrow than normal, will naturally have some effect upon the situation, enabling shippers to go into the markets in the West where their fuel formerly went as a matter of course.

This effect, however, will not be felt at once to any considerable extent, both for the reason that these shippers and operators will not immediately be able to resume connection with the channels through which their coal formerly moved, and that the same situation exists in the West as here, with reference to the supply of coal in the hands of consumers. In fact, shippers in this section have received direct appeals not to make shipments into the Western markets just now, as it is feared by the trade there that such a move would tend to demoralize the market utterly, by bringing about a large supply of unneeded spot coal. The situation will, therefore, work itself out only very slowly, and it is not by any means cheerful.

LOUISVILLE

Domestic demand slightly better, due to small stocking running low and slightly colder weather. Steam demand very weak. Domestic values up slightly due to lack of steam demand to take care of screenings. Mines operating three days.

There has been some slight improvement in domestic demand during the past few days, due to small stocks beginning to run low and slightly colder weather. However, at that the retailers are far from busy, some reporting that they are not working half of their equipment capacity. Some houses report that customers stocked so heavily that they have not used half of their coal as yet, and that business is dull. Collections are fair only.

The general demand for steam coal shows little improvement, and there is not much encouragement just now. Discussions of the prospects for early shipments to the lake region have brought out the fact that the North is still well stocked, and may not start buying before midsummer, unless severe weather develops within the next month or two. In the local field there is little demand, as industrial concerns are not busy, some being almost down. Practically all of them have good stocks on hand.

Mines are in operation about three days a week as a maximum, many putting in only two days. These mines for the most part are the large ones which have good sales organizations. The small mines in many instances are not attempting to turn a wheel, being unable to secure business.

Prices on steam coal are being shaded by many operators at the present time on immediate delivery stock, especially screenings. However, some of the large operators have already advanced prices 15c. to 25c. a ton on domestic coal, due to the fact that it is costing more money to get it out, and they have no market for the resulting screenings. However, prices are generally well maintained in the local market and field. Retailers are holding on firmly, feeling that price cutting would not really get them anything in the long run.

BIRMINGHAM

Inquiries for steam coal slacken, but domestic market remains strong. Better grades of steam coal moving fairly well, while the poorer grades are not being so readily absorbed. Shortage of domestic fuel still very pronounced.

There is not an active demand for steam coal in the Birmingham market at this time, though sufficient business is being booked to take up the output of the mines prodcing the better grades of fuel, taken in conjunction with the contracts on hand. There is some accumulation of cheaper grades of steam coal—Big Seam and the like—though the surplus is not yet sufficient to affect market conditions. Coals of the poorer quality are being moved with more difficulty than formerly. The present hesitancy in the market is not due to any decrease in requirements, but to a desire on the part of consumers to await the transition from Government control to the normal influences of supply and demand, and such price adjustments as will necessarily follow, based on quality instead of cost of production. The prices of some grades will probably be lowered slightly while others will be advanced.

The supply of domestic coal has been so pronounced since Apr. 1, 1918, that the removal of Government regulations will undoubtedly pave the way for an increase in prices of the higher grades. Although the present winter has been an exceptionally mild one so far, there is little coal stocked on local yards, retailers delivering the fuel to customers as fast as received.

Coke

CONNELLSVILLE

Further market decline. Settlements on contracts. Operators restricting production.

The furnace coke market has weakened farther and is now quotable at $5@5.50, the Government limit, which expired with January, having been $6. There has been little activity in the open market, but spot coke of fairly good quality has been readily available in the past few days at $5, and possibly in most cases with a margin to brokers besides. There has been little buying, furnaces being well covered by contracts, with a few exceptions, and depending on contracts to keep them supplied.

There have been active negotiations in connection with contracts calling for an agreed price from time to time whenever Government control should come off. These negotiations are regarded as establishing the real value of coke better than the odd lot sales that may occur in the open market. Service plays an important part in determining coke values, as it is expensive to the blast furnace to receive either too much or too little coke from day to day, and thus higher prices may be paid willingly on contracts, than the prices at which odd lots could be picked up. One prominent coke producer has proposed to contract holders that $5.50 be the settlement price for February deliveries, and it appears that most of this interest's contract holders have accepted the proposal. In other quarters, however, settlements have been made at not over $5.25, and in some instances $5 appears to have been done.

The coke operators express decided determination to regulate production to demand and avoid the dumping of any coke. The present experiment may be more successful than some past attempts. Operators recognized that there should be a decline from the Government limit and insist that the decline that has occurred does not presage a continually declining market.

The foundry coke market has not really been developed, demand being so light. Under no particular pressure makers of standard foundry coke have reduced their price 50c. from the Government limit, and there are indifferent brands available at less, The market is quotable at $5@5.50 for furnace coke and at $6.50 for standard grades of foundry coke, per net ton at ovens.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Jan. 25 at 277,324 tons, a decrease of 14,008 tons, and shipments of raw coal at 189,707 tons, a decrease of 5986 tons.

Buffalo—The demand is light. The furnaces do not get the cue yet as to what is expected of them, and they are not ready to buy in advance. With lighter running the local byproduct coke plants can about supply the needs here. With another plant running the demand ought to be taken care of in that way. It will be some time, though, before that is ready. Fuel coke will remain slack till there is a better movement in bituminous coal, which may not be right away. Vessel owners are getting no offers of rates on ore, but look for about the same rate and season in general as last year.

Middle Western

GENERAL REVIEW

Matter of prices now occupies chief interest. Region saturated with coal and practically little tonnage is moving. Franklin county operators talk of price increase.

The topic of the week is prices. On the one side there are the operators, who are face to face with their costs, know exactly what their properties can do, and are afraid to indulge in any price-cutting tactics. On the other side are the purchasing agents, with the big steam users, public utility plants, etc., who are confidently looking forward to a break in the market. They are doing everything they can do to bring about such a break. They claim they are taking their cue from the railroads, who, by the way, are the largest coal-consuming public the operator has to look to. What the result of this struggle will be no one can accurately foretell. Of course, there will be readjustments here and adjustments there, and in certain isolated cases prices will undoubtedly advance.

If common gossip is to be believed, the operators are not in a position to make any concession in regard to price, and at the same time operate their mines on a money-making basis, no matter how narrow the margin may be.

The weather has been miserable, so far as the coal man is concerned; in fact, the weather has been so mild that it is not necessary to go to Florida to enjoy the spring breezes. We are getting them right here in Chicago and the Middle West. This warm weather is a tremendous factor, as it affects both the domestic and steam consumer. If any actual figures are kept of the coal consumed this year, we venture to predict that these figures will be far below the average.

So far as actual market activities are concerned, there is practically no coal moving. The tonnage reports from the Geological Survey, for the first two weeks of the new year, were rather encouraging, as they showed a decidedly upward trend, but we do not believe that this upward movement will be maintained, as the country has reached a state where it is practically saturated with coal.

One of the purchasing agents for a railroad, having a huge mileage in this territory, was approached with the idea of selling him some coal. He listened attentively to what the operator had to say, and showed an intelligent interest in the problems that the operator was face to face with. He did not have much to say, however, and toward the end of the interview he remarked that if coal was offered to him for 10c. per ton, he would be unable to avail himself of the bargain, because his railroad has on hand as much coal as it can possibly use, both now and in the near future. This example shows pretty accurately the condition of the market.

There is considerable talk going around that the Franklin County operators, effective Feb. 1, will increase the prices from $2.55 per ton, f.o.b. mines, to $2.75 per ton, for the prepared sizes and that this 20c. per ton increase will be general on all the coal they produce. The Franklin County people have been well and favorably known for the excellence of their product, and if anyone is to obtain an increase over the Government price, after Feb. 1, these people are in a position to do that. This experiment is going to be watched with interest by the rest of the coal men.

When the news first came out, to the effect that the zone restrictions were to be lifted after Feb. 1, there was a lot of promiscuous buying of Eastern coal; but this buying has practically all stopped, as the users of Eastern coal realize that the coal season is practically done. It is safe to say that the majority of tonnage of Eastern coal moving into the Mid-West territory is shipped for domestic purposes only.

It has now been from eight to ten weeks since there was anything like an active market in the Mid-West territory, and it is believed that this inactivity will have resulted in the reduction of a great many storage piles, and that a substantial number of steam users will once more be in the market. It is hoped that this will be the case, because not much more is to be looked for this year from the retail trade.

CHICAGO

Retailers making every effort to dispose of their low-grade stocks to make room for Eastern fuels. Little signs of activity in steam trade. No concern about anthracite.

The retailers of Chicago are bending every effort toward cleaning up their yards of low-grade Illinois and Indiana coals, preparing to receive a new stock of the high-grade Eastern products, which they ordered to be shipped around Feb. 1. It is believed that whatever Eastern coal is to move in here has already been ordered, as the dealers have come to the conclusion that they have nothing more to expect from the winter months. This season has been the mildest experienced in many years, and it will not be an exaggeration to say that the average retailer will go into next year with a considerable supply of this year's coal on hand.

The Chicago steam trade is showing little signs of life. The best that can be reported is a car sold here and a car sold there, practically no sales being made of any substantial tonnage. The anthracite situation has ceased to be a factor in the market, as the public is geting all the anthracite at this time that they wish, and getting it without restrictions.

MILWAUKEE

Little doing in coal on account of mild weather. A drop in bituminous coal expected in February. Pocahontas reappears in the market.

"Nothing doing" is the laconic answer to all inquiries as to the state of the coal market. Mild weather has put a damper on both city and country trade, and deliveries are at such a low ebb that most of the trucks and teams formerly employed in the business are out of commission. Consumers of anthracite who were supplied with only two-thirds of their normal supply are refusing the remaining one-third, claiming they have sufficient fuel to last. Shipments to the interior are also nomiral in character.

Dealers predict a cut in prices of soft coal in February, following aggressive marketing on the part of Western producers, whose output has been greatly stimulated by the demands of the war period. There is no prospect of a letting down of anthracite prices, however. The nearest approach to a cut in this grade of coal was made by one dealer who receives his supplies by rail and who has waived the premium of 40c. per ton which has been allowed on rail coal.

A return of zero weather would help matters, but the spring will have to be unusually protracted and inclement to exhaust the piles of coal on the docks.

Pocohontas promises to become a factor in this market again. Dealers are receiving offers of the screened product at $3.25 at the mines.

ST. LOUIS

A demoralized market continues on everything. Summer weather prevailing and no steam or domestic demand.

The market situation in St. Louis is still demoralized, owing to the mild weather. There is practically no demand for domestic coal of any kind. Some Standard is moving into the poorer sections of the city, and the little anthracite that was ordered is being delivered, but a goodly portion of these orders have been cancelled, the consumer feeling that the weather conditions will not justify the putting in of any high priced coal at this time. The result is that the dealers are going to have a lot of anthracite egg unless cold weather comes in.

The country demand for domestic coal is similar to that of the city demand. Steam business is almost at a standstill. Many steam plants are working only half time, and some are not working at all. The storage piles are being used in many places, and even the railroads are not buying as they intimated they would. Instead they are resorting to their storage supplies. Never before at this season of the year has the market been in anywhere near as bad a condition as at the present time.

Car supply is good on practically all roads, but the movement on some roads is slowing up for no apparent reason. In the Standard district mines are idle for as long as ten days at a time. Screenings are piled up so that nothing else can be loaded, and seem to be the only size right now for which there is no market of any kind. The price got down to $1.20, and that does not move them. Two-inch Standard lump is still around $1.50 to $1.60, and 6-in. lump from $1.75 up. There is not much prospect for better times ahead in the Standard field.

In the Mt. Olive district prices, as a rule, are holding up to the Government maximum of $2.55. This field, however, is not working much better than the Standard field, although a fairly good tonnage is moving north. The tonnage coming into the St. Louis market seems to decrease on account of the difference in price between Mt. Olive and Standard.

In the Carterville field, Williamson and Franklin Counties, the past week showed a decided change for the worse. Many mines are idle because they have no orders, and others because they cannot move the screenings and nut. In a general way the Franklin County prices are being maintained, while in Williamson County there has been some cutting.

Effective Feb. 1, the Williamson and Franklin County organizations, under the leadership of F. C. Honnold, raised the price of domestic sizes to $2.75. These organizations, it is understood, will be merged as one, with Honnold as the directing head, J. L. Kieflein having resigned as secretary of the Williamson County organization.

A break in the price of these fields cannot be expected. These operators are convinced that they should get more money for their coal and they are going to demand it. The Government price on this coal has been $2.55, with special preparation of 10c. in some cases. There is much resentment among the retail trade and the steam users over this action on the part of the operators, but inasmuch as the operators are organized solidly in Franklin County, there is not much chance to make a change.

The conditions in these fields will improve rapidly with colder weather. Car supply is plentiful and movement fairly good.

COAL AGE

Volume 15 New York, February 13, 1919 *Number* 7

Enlarging the Coal Operator's Field for Profits

THE inherent ambition of every coal producer to dispose of his product direct to the ultimate consumer is just as much of a fundamental law in industrial life as is that physical law which concerns the action of gravity. Though the process may be slow and circuitous, the final result need never be in doubt; it is all a matter of evolution.

Unlike a great number of commodities which readily lend themselves to a direct exchange between producer and consumer, coal has always been a product which necessitated the services of an intermediary. First it is bulky and difficult to handle; then there is the wide geographical distribution of the product. Furthermore, the vast army of consumers scattered over the United States are but slightly acquainted with the source of the coals they use, and they so limit their sphere of activities and their knowledge of fuel matters that the middleman naturally came into existence and has performed a valuable service.

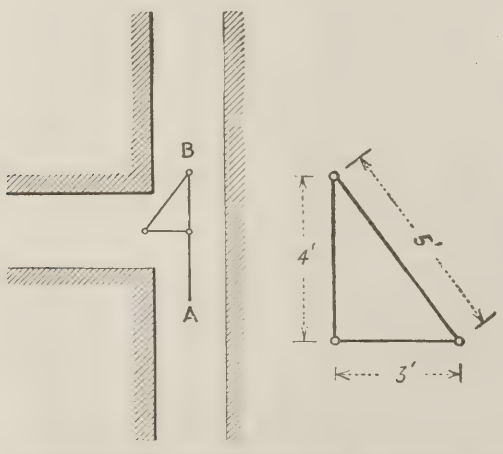
In truth, the middleman in the coal industry would be a permanent fixture were it not for the fact that severe competition and stern labor demands render it necessary for the operating companies to extend their sources of income. One way for the producer to do this is to assume the functions of the middleman. Competition always means consolidation. The middleman is the only factor acting between the producer and the consumer of coal upon whom a "saving" operation can be performed. Production costs have been reduced to a minimum, and with the return of bitter rivalry for markets there arises a need for increased profits. The logical way out is for the operator to add distribution to his field of productior

No one familiar with the situation can honestly question the value of the service which the middleman has performed. His is a work that must be recognized as indispensable even by those who regard him with disfavor. He may be eliminated, but the service he performs cannot be done away with, although the producer may take over his job in the ordinary evolution of things.

For several years there has been a decided trend along this line. More and more of the larger producing companies are establishing selling agencies in the various important cities. These agencies, however, up to the present time have catered mostly to the large consumers, including the railroads, leaving the small consumers to the middleman. The disturbed markets of today are causing the coal operators to reach out for this business, which individually does not amount to much, but in the aggregate totals a large tonnage. In nearly all states retail establishments are either being erected or are being purchased by the coal producers. New England in particular has witnessed such an invasion of the distributing field.

The coal industry for several reasons has never stood high in public favor. It has had few friends at court and has always been the popular object of newspaper attacks. Mine operators are only just now commencing to see the wisdom of standing together. Diffidence must disappear if profits are to remain. The public must know the true story of coal. Nothing is gained by an attitude of submission and silence.

Real efficiency will only come when the coal producers learn the art of distribution as thoroughly as have the meat packers and the oil refiners. Genius for organization is not confined to any single line of business. Anticipating such a process of development, the alert middlemen are fortifying themselves against approaching extinction. Some are becoming the sole owners of new and promising mines; others are consolidating their interests with those of friendly producers. In other words, coal distributors are not defying the inevitable, but are meeting it halfway. Thus the middleman in name may be eliminated, but his function will still go on, like John Brown's soul.



IDEAS AND SUGGESTIONS

Method of Driving Rooms Without the Aid of Regular Sights

BY OSTEL BULLOCK
Cleaton, Ky.

There are many men who study out the easiest and the quickest way to do things. In the mine where I am employed at present we have an engineer who does not get around oftener than once a month, and sometimes it is longer than that. Consequently, we had trouble from new rooms getting off centers before we could get sights put in them. This was annoying, as in such a case we would have to relay the road and retimber the places. Furthermore, getting off center weakened the pillar on one side and left a lot of coal on the other. I finally made a contrivance that answers the purpose. It can be constructed by any one in a few minutes and is accurate enough for driving short distances where no engineer is at hand to set points.

I took three small rings, as shown in the diagram. I then cut three lengths of small string—3, 4 and 5 ft. long respectively. After fastening these three strings to the three rings, I had a "triangle." To use this I take any two points *A* and *B* on the entry center line in front of a roomneck opening. Between these two points I strike a chalk line. Then, having found the intersection of the roomneck center line and the chalk line already struck, I place the ring forming the intersection of the 3- and 4-ft. strings at this point with the 4-ft. string extending along the chalk line in the entry. The 3-ft. and 5-ft. strings are then drawn taut. The room

HOW TO DRIVE ROOMS WITHOUT REGULAR SIGHTS

sights will be along the 3-ft. string. Then, by putting in a spad at the end of the 3-ft. string, and one on the entry, the set of sights thus made will serve for driving 60 or 70 ft. with only a small error.

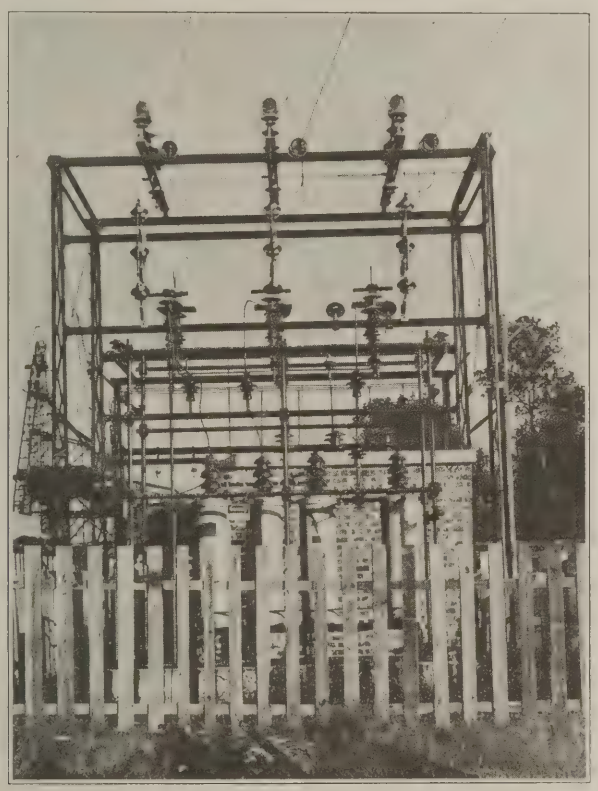
Much of the accuracy obtained depends upon the care taken in placing the sights and the size of the strings and rings used. To turn at a 45-deg. angle it is only necessary to sight from the same point on the entry to a point in the center of the 5-ft. string.

To Remove a Broken Handle from Hammer or Sledge

BY A. P. O'CONNOR
Homer City, Penn.

Much annoyance is occasioned by the breaking of a hammer or sledge handle when there is no means at hand wherewith to remove the piece that remains in the eye. A good way in which to remove the troublesome piece is to place it in such a position that the eye is directly over a hole dug in the bottom, or one end may be placed on top of a rail and the other end on a tie (or similar arrangement), so that there is nothing to hinder the piece from coming out. Then throw a handful of dirt on top of the eye and pound it with a pole, ax, hammer or some such tool. Repeat this operation as rapidly as possible and note the surprising ease with which the piece will be driven from the eye.

REMOVING PIECE OF BROKEN HANDLE



New Type of Outdoor Substation to Meet Severe Service Requirements

BY H. W. YOUNG
Chicago, Ill.

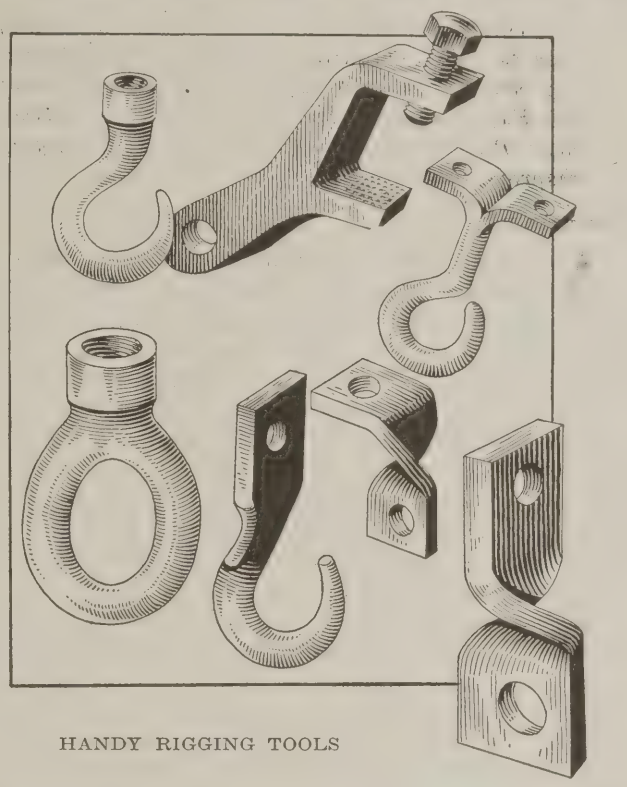
The increasing tendency of coal-mine operators to purchase power has resulted in the development of outdoor substations to meet the severe requirements of this service. There is a growing recognition of the fact that insulation should be of high quality so that heavy deposits of dirt will not cause failure by insulation leakage. This means that the equipment should have what is generally termed an abnormal factor of safety. This can be secured by the use of higher rated insulators than are ordinarily employed.

A new type of outdoor substation designed to meet the imposed conditions is herewith illustrated and a description of this equipment will be of interest at the present time. The power is made up of expanded steel sections heavily coated with rust-resisting paint, and so designed that it is shipped in sections easily bolted together at the point of installation. At the tower base is located a house of such dimensions that the high-tension auomatic oil switch and metering equipment can be easily installed and operated therein. The transformers on the opposite side of the tower are located within a steel inclosing frame which also carries the bus supports for both high- and low-tension transformer buses.

Control of the high-tension side is secured by means of a three-pole air-break switch operated from ground level by means of an interlocking switching mechanism. Lightning protection is secured by means of choke coils mounted on the switch base and so connected that incoming disturbances are reflected to the electrolytic arresters where they can be quickly discharged to ground. Between the line and the arrester are mounted

NEW TYPE OF OUTDOOR SUBSTATION

three single-pole disconnecting switches with limit fuses. By opening these switches the arresters can be safely inspected and adjusted. In case of arrester trouble, the limit fuse will operate and prevent excessive current flow.



The high- and low-tension transformer buses are carried on bus supports having insulators of the same type as are used on the switching equipment. The general design is such that unskilled labor can be employed for both installation and operation, thus keeping costs at a minimum.

"Reputations are easily made; character must be hammered out on the solid forge of time."

Rigging Helps for Quick Erection of Block and Tackle

By Charles H. Willey
Concord, N. H.

The handy rigging tools shown in the accompanying illustration are all quite simple, yet they have proved useful; for with this assortment in the tool box or locker a block and fall or chain tackle can be rigged up

HANDY RIGGING TOOLS

readily and quickly almost anywhere. There is no need of dimensions or descriptions of these devices, as they must be made to suit local needs. However, a couple of clamps such as those shown have proved the handiest of the lot. The hole in the lug should be sufficiently large to receive a tackle hook, and if heavy work is to be handled the clamp should have two securing screws.

Carbon and Commutator Wear

By R. E. Hellmund
East Pittsburgh, Penn.

Carbon manufacturers, as well as builders of dynamo-electric machinery, have made numerous tests to determine contact resistances, friction losses, etc., of various brushes. While such tests are of interest, they contribute little toward the real practical need; namely, a substance that can stand high current densities and high sparking voltages with small wear.

In order to develop carbons having such qualities, it would seem essential to first make tests to determine how the wear is affected by current density, sparking voltage and peripheral speed. Present indications are that with many commercial carbons appreciable densities can be used if there is no sparking voltage, while sparking potentials up to 15 or even 20 volts across the brush cause little wear at certain speeds, if the current density is low enough. More data along this line should be of great advantage.

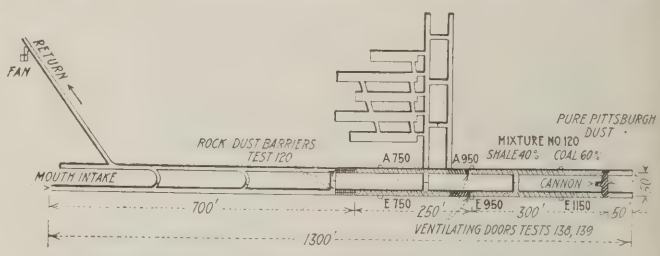
Effect of the Velocity of Ventilating Current Upon Mine Explosions

By G. S. RICE and W. L. EGY
United States Bureau of Mines, Washington, D. C.

SYNOPSIS—*A pet theory of many mining men is that ventilation should be reduced during firing. Certain experiments carried on at the Experimental Mine of the Bureau of Mines near Pitsburgh, Penn., would tend strongly to disprove this theory.*

A LARGE number of mining men, particularly in the Southwest, are of the opinion that the velocity of the ventilating current has a great influence in the origination of coal dust explosions. On this account they recommend that the fan be slowed down at shot-firing time, and in some cases have advocated closing the mine openings. The supposed basis for this theory is that a high-velocity air current would furnish more oxygen for the development of the explosion than a low-velocity air current; and further, that if the openings of the mine are not closed, air might enter and, traveling toward the advancing explosion, furnish it with more oxygen.

It is evidently assumed that the oxygen in a quiet atmosphere or in a current moving in the same direction as the explosion is not sufficient to feed the explosion and that a supply from other points is necessary for its development. In connection with this theory a number of tests made in the Experimental Mine of the Bureau of Mines are of special interest.



The great majority of the explosion tests in the Experimental Mine have been made with low-velocity air currents, the velocity being about 100 per minute. There are also many tests in which the velocity ranged from 100 to 200 ft. per minute. There are three tests, however, which were made under conditions which should certainly have shown some result of the velocity if this were a factor; these are tests Nos. 138, 139 and 120, in the Experimental Mine series.

In test No. 138, pure coal dust was distributed from the offset in 1250 cutthrough to E and A 950 (see accompanying diagram), at which points the entries were closed by rock-dust-protected ventilating doors, the entry door opening inby and the aircourse door outby. These doors were closed during the test so there was no air current moving in the explosion zone. The explosion was originated by firing the usual charge of 4 lb. of black blasting powder from the cannon in the offset, and the resulting flame or explosion velocities were high, and pressures strong.

In test No. 139, the arrangement of igniting the shot and the zone was similar, except that outby a coal dust ignition zone, in the 1250 cutthrough a mixture of 50 per cent. shale and 50 per cent. coal was distributed at the rate of 4 lb. per foot to E and A 950. No difficulty was encountered in this test in obtaining an explosion, the development being roughly symmetrical in the two branches with pressures of 25 and 17 lb. at E and A 950 respectively.

If closing the explosion zone so near the origin had no effect in preventing the origination of an explosion, closing the openings of an operating mine which may have large areas of open workings underground from which air would be available to assist in the explosion, were the theory mentioned correct, would certainly have no influence. These two tests show that for the development of a violent explosion there is no necessity for oxygen supply other than that present in the air in the explosion zone.

In test No. 120, June 11, 1914, which was made in the presence of many of the members of the Mine Inspectors' Institute of America, a high-velocity air current was used. The ignition zone in the 1250 offset and cutthrough was prepared with pure Pittsburgh coal dust, while in the entry and aircourse outby to E and

SHOWING HOW ROCK DUST WAS DISTRIBUTED

A 700, a mixture of 60 per cent. coal dust and 40 per cent. shale dust was distributed at the rate of 3½ lb. per foot. Barriers of various kinds limited the explosion zone at different points. An air current with a velocity of 850 ft. per minute was intaking on the main entry and returning on the aircourse. The arrangement permitted a comparison of the development of an explosion in two parallel entries, with dust distributed in the same manner and amount in each, but with the main entry swept by a high-velocity air current traveling toward the origin, while in the aircourse the air current traveled away from the origin.

When the shot was fired, dust clouds came from both entry and aircourse openings. Inspection of the flame recorders indicated the explosion had reached the end of the zones in the two entries. The explosion was a relatively weak one, with low velocities, as was intended. This was attained by using a high percentage of shale dust in the dust mixture.

When the instrument records were plotted it was found that the development of the explosion in the two entries was quite similar, the velocities in the aircourse, which was the "return," being a little greater than those in the entry, which was intaking. It required 3.2 sec. for the flame to reach E 1150 and 2.9 sec. to reach A 1150, while the records at E 750 and A 950 respectively were 6.5 and 5.1 sec. It will be seen that the velocity of flame from the origin to A 1550 was only a little greater than

that to E 1150. The average, as indicated by time of melting of foils, in entry and aircourse between stations 1150 and 750 were 182 and 121 ft. per second respectively. The pressures developed were light, being 5 lb. at E 1150 and E 750, 2 lb. at A 1150 and A 750. Thus there was practically no difference in the development of the explosion in the intake and the return.

It is believed from this and other tests that the velocity of the air current has no appreciable effect on the development of the explosion. The first effect of the shock wave of the igniting shot is to send out a pressure wave radiating in all directions, which reverses the direction of the air current when the latter is in the opposite direction. This is clearly shown by the pressure diagrams and records of the air vanes in many of the Experimental Mine tests.

It therefore makes no difference, so far as the propagation of an explosion is concerned, what the velocity was before the shot was fired, since immediately afterward the movement is away from the shot in all directions. After an explosion has passed any point, the current of gases and residual air reverses and flows back toward the origin, followed by fluctuations until equilibrium of atmosphere pressures is established throughout the mine.

It is therefore concluded that the theory of slowing the fan or closing the mine openings to reduce the possibility of the origination of an explosion is founded on false premises, and there is no reason in favor of following the practices founded on this theory. On the contrary, there is great reason for not doing it since the slowing down of the air current may permit the accumulation of gas in some parts of the mine and fail to carry off effectively the gases resulting from the shotfiring.

Algerian Market for American Coal

By Consul Arthur C. Frost
Algiers

With the exception of a negligible quantity of lignite and bituminous deposits, Algeria is dependent upon other countries for its coal supply. Before the war this commodity was imported principally from Great Britain. France, Germany, Holland, Belgium and the United States supplied the remainder. Since 1916 a large portion has come from France, in accordance with the policy of tonnage conservation.

Due to the difficulties of transportation, the imports of coal have rapidly dwindled since the beginning of the war. The total imports into Algeria, including bunker coal, have been as follows: 1913, 2,251,000 metric tons; 1914, 1,692,000 tons; 1915, 1,491,000 tons; 1916, 1,153,000 tons; and 1917, 757,000 tons.

For interior consumption the quantity and value of the coal and coke imported into the colony were as follows: 1913, 530,622 metric tons, value $2,073,000; 1914, 427,624 tons, value $2,685,000; 1915, 313,937 tons, value $3,722,000; 1916, 325,798 tons, value $6,661,000; 1917, 228,262 tons, value $8,310,000. Although the quantity received in 1917 but slightly exceeded one-half the quantity received in 1913, the value was over four times as much.

According to the statement of an official of the State Railways, Algeria was receiving monthly about 20,000 tons of coal the latter part of 1918. The State Railways are charged by the Government with the distribution of coal to all industries as well as to the railway lines in North Africa, including certain lines in Morocco. Double this quantity is needed to enable industrial establishments and public utilities to resume normal operation and to supply householders, who have been almost deprived of coal for the past two years.

Because of higher freight charges, American coal has in the past been unable to compete to any extent with British coal. The quantity and value of the coal imported from the United States from 1912 to 1915, the latest year American coal was received, follow: 1912, 3810 metric tons, value $17,000; 1913, 24,917 tons, $112,000; 1914, 22,062 tons, $102,000; 1915, 6455 tons, $68,000. In the spring of 1917 negotiations were practically completed for the purchase of 150,000 tons of American coal for delivery within a year. Owing to the entrance of the United States into the war and the requisition of tonnage this contract, arranged with the American coal companies through the Société Internationale d'Expansion Industrielle et Commerciale, 32 Avenue de l'Opera, Paris, France, could not be fulfilled.

The construction of a large American merchant marine presents an opportunity for the development of the coal trade of North Africa. In addition to coal for internal consumption in Algeria, the United States should be in a position to supply bunker coal, especially for its own ships. Before the war Algiers was one of the principal coaling stations on the Mediterranean. Due to war conditions, however, the number of vessels calling here for supplies has steadily dwindled, and, in fact, during the past two years Oran has exceeded Algiers in supplying vessels.

Furthermore, Algeria presents opportunities for return cargoes perhaps greater than certain other Mediterranean regions offering markets for American coal. To a large degree American exports to the Mediterranean consist of bulky commodities, such as cotton, grain, coal, petroleum, machinery and metal products, and exports from this region are largely made up of articles of small volume but of relatively high value, notably food products. The result is that most vessels westbound are in ballast or carry small cargoes only.

Algeria, however, exported before the war considerably over a million tons of iron ore, and the full resources of the colony in iron ore are yet to be realized. The region about Bougie has been called the Algerian "Bilbao." The colony exported as well considerable quantities of zinc, lead and some copper. Manganese, mercury, and antimony are also found. A great part of Algeria's minerals were before the war exported principally to countries other than France. England and Holland were the best customers, followed by Belgium, Germany, Austria-Hungary and the United States.

The coke production of the United States in 1917 was about 56,000,000 tons, of which approximately 34,000,000 tons was produced in bee-hive ovens and over 22,000,000 tons in the byproduct type. If the 34,000,000 tons of coke had been made in the byproduct oven, some 9,000,000 tons of coal might have been saved; this saving represents about 10 per cent. of the coal used for domestic purposes in 1917.

Missouri Coal Trade Conditions in 1918

By E. J. WALLACE
St. Louis, Missouri

IT WAS NOT with a flourish of trumpets that 1918 was ushered in by the coal trade. In fact it was unlike the incoming of the two previous years, for the Fuel Administration had a firm hand on the coal business in St. Louis.

The steam trade as a whole fared better in St. Louis than it did in any other city in the country east of the Rockies. No record has been made of any factory or industry going down for the actual need of coal. This was due chiefly to the splendid work of the St. Louis Fuel Committee, which was helped materially because Lieutenant-Governor Wallace Crossley, Fuel Administrator for Missouri, had jurisdiction over the East St. Louis, Ill., switching limits. As a result the available coal was distributed so that everyone got some.

The domestic consumer began the year with a hope that sufficient coal would come in to enable the delivery of more than half-ton lots. Things were more critical with the householder than with steam plants. There was little coal in the homes, and for the first few weeks the city was sorely beset. At this time the city opened its municipal coal yards in the poorer sections, and coal was sold in small lots to the needy.

Little Carterville coal came in as the year opened. The same applied to DuQuoin. The railroads seemed to get most of it, from the St. Louis viewpoint. Mt. Olive was the chief high grade, and Standard coal, which in normal times was beneath recognition for general domestic use, became a highly esteemed fuel.

Railroads Bought a Large Tonnage

The railroads drained both the Mt. Olive and Standard fields of an enormous tonnage over what they had taken in the past. The Terminal Railway of St. Louis, which was without any storage supply through lack of foresight, confiscated coal indiscriminately and was called to task by the Fuel Administrator. Incompetent railroad fuel agents were brought into the limelight, and for once their plan of holding up the operators proved their undoing and an expensive problem to their companies. There was no Pennsylvania anthracite coming in during the first few weeks of the year and no smokeless at all.

The coldest weather for 30 years was experienced in January, and the snow at times tied up everything. The Laclede Gas Light Co. was ordered to take conservation measures on account of its storage being used up. The Anheuser-Busch Brewing Association was ordered to sell to the gas company any part of 14,000 tons of Pittsburgh coal that it had in storage for the past 14 years. This saved the day for the gas consumer in St. Louis. The closing order affecting non-essential lines of business issued by the State Fuel Administrator saved gas and also light.

January was the real critical month in St. Louis and the territory adjacent. Mines in the Standard field, upon whose output St. Louis depended, were idle for from a week to ten days at a time through many causes, principally poor rail management.

February brought somewhat easier conditions. The Fuel Committee on Feb. 1 estimated that St. Louis was getting along fairly well with a shortage of 95 cars per day. The steam and domestic requirements were shown to be 550 cars per day. The retail demand was from 250 to 300 cars per day. There were 243 essential food and war contract plants that had to have 12,000 tons per week, and 227 other essentials needed 15,000 tons per week.

Much improvement was apparent as the month progressed, in spite of the Illinois Central R.R. and the St. Louis Terminals going to pieces. Embargoes were put on by the carriers and removed by the Fuel Administration. Cars were furnished mines one day a week, and it was almost another week before they were moved and from one to two weeks before they were delivered. There was much uneasiness over the proposed zoning and the elimination of the jobbers' margins. This affected the country trade seriously. To help them out, especially in southern Illinois and Arkansas, the Missouri Fuel Administrator diverted several cars of coal from St. Louis.

Roads Confiscated Domestic Coal

No Carterville came into St. Louis, and on the Missouri Pacific lines in southeast Missouri, Arkansas and Louisiana the situation was alarming. No rates from other than the Carterville field were in effect, and the Missouri Pacific confiscated nearly all the domestic coal that went that way.

Toward the end of February the weather moderated and conditions became easier. Some 1500 tons of anthracite had moved in, but no smokeless, and nothing from Arkansas. The carriers did not, however, show much improvement in their work. Mt. Olive coal had become easier, and Standard was available for some storage supplies although the carriers were apparently taking more tonnages from all fields than in the previous month. The mines supplying St. Louis for this month averaged from nine to twelve days' work, the poorest showing being on the Louisville & Nashville and Illinois Central lines.

At the close of the month retail conditions were easy, and when March opened the situation did not occasion any worry. The early part of March presented the weakest link in the chain, the Louisville & Nashville putting on embargoes without any valid reason. This carrier and the Illinois Central rendered extremely poor service until after the middle of the month, when there was an improvement. At this time the Terminal situation became somewhat like normal, and more prompt delivery resulted.

The supply of Mt. Olive coal became more plentiful, and at the end of the month there was an oversupply. However, it moved in heavy tonnages to Nebraska and the northern market. Carterville was scarce, little coming in at any time, while Standard became a drug on the market with unbilled coal at the mines and at East St. Louis, with some slight price reductions here and

there. The steam trade bought somewhat begrudgingly, and steam sizes were also heavy. The domestic demand was good in the early part of the month, but at the close it was not a factor. During the month about 3000 tons of anthracite moved in. There was no smokeless and no Arkansas.

The matter of contracting was purely a gamble, but many contracts were made during March. Most of these indicated that the shipper had less faith in future high prices than the consumer. The usual contract called for a maximum and minimum tonnage of the screened sizes, with the understanding that if conditions warranted it mine-run could be shipped at the Fuel Administration's price at time of shipment. These contracts for the most part just assured the buyer of his fuel at the Government price. It was a protective policy. The big railroad contracts were made at less than Government figures. This was where the operator was not so sure of the future as the consumer.

Opening of Coal Year Discouraging

The coal year opened in a most discouraging way to the shippers. There was no steam market. It could not be made. Even price would not do it. Sizes that were unavailable for many months, like No. 2, No. 3, No. 4 and No. 5, were going begging. Embargoes against Chicago by the Wabash and Chesapeake & Ohio was the principal cause, and the country demand ceased so suddenly that it hurt the feelings of some shippers who had saved postage by refusing to answer country inquiries for many months prior to Mar. 1.

For a few weeks previous to Apr. 1 an enormous tonnage of all kinds of Illinois coals eased the St. Louis situation. During April the St. Louis market was glutted with this coal, and prices on Standard coal were cut to suit the buyer if one could be found. With the same Government prices in effect as on Jan. 1, Standard lump went down to $2.25 and less, with mine run at $1.90 and screenings at $1.65. This condition prevailed to the end of the month.

Mt. Olive coal was plentiful during all of April, and it held to the maximum Government price. The Carterville situation was discouraging. In an effort to induce the public to buy the most available fuel, and to induce the retailer to store as much as possible, the St. Louis Fuel Committee increased the price of retail coal 30c. per ton. This was 21c. less than the retailers asked, as they produced figures to show that it cost $1.45 to sell coal at retail. The hauling charge is $1 of this. The prices set were a surprise to the public, who had expected a reduction.

Retail demand became good on Carterville coal, just the opposite of what was expected. Dealers had more orders for this grade than they could possibly fill in three to four months. It took from two to three weeks to get a car from the Carterville field, 100 miles away, to St. Louis over the Missouri Pacific and the Illinois Central. The general impression was that some of the roads were trying to render such service as would cast a reflection on Government control. Even the Terminal slipped back several notches, and conditions were trying. There was a good movement of anthracite during the month, several thousand tons coming in, but no smokeless and no Arkansas except the bituminous variety.

In May there was practically no anthracite moving in except some off-grade, off-size stuff, and no smokeless and but little Arkansas. The transportation problem remained as in April. The local steam market went down to its low ebb, and there were hundreds of cars of screenings unbilled that kept down the delivery of screened sizes. The Standard field showed improvement in other sizes as the month advanced, and there was a better tone to the market. This was helped by the railroads coming in for fuel. As a matter of fact they saved the Standard field from absolute demoralization. Railroad fuel is mine-run, and the screening problem therefore vanished. There was plenty of 6-in. lump and somebody got a lot of 6-in. mine-run.

The domestic demand from apartments and off-the-rail plants improved. The Mt. Olive situation was similar to the Standard on screenings, but it improved toward the end, aided by railroad orders and a much better domestic call.

The Carterville condition became alarming toward the close of May. Many dealers were far oversold, and the tonnage became smaller week after week. Then the operators refused to take on more orders until they caught up with those on file. The same applied to the DuQuoin field. There was a break in the maximum prices on Carterville screenings, which went as low as $2, with DuQuoin at $1.75. Standard went to $1.40 at this time.

At the close of the month there was a slipping back to former conditions apparent in the Standard field. This became more pronounced in the early part of June, at which time railroad buying let up. When the roads came into the market again coal was cheaper. So it was for everyone else who could use Standard, but the tonnage moved was nothing to what the condition required.

Freight Rates Advance on Coal

There was a fair movement of everything but screenings for a few days prior to June 25, when the freight rate advanced 20 per cent. on all coal. The Standard market pulled through June in somewhat worse shape than in May. Mt. Olive held its own. There was just demand enough for the supply. Some of this went into storage, while practically no Standard was considered. The Carterville and DuQuoin situation seemed to get worse. The railroad tonnage of these coals became greater, so did the domestic demand, which was insistent.

The heart-breaker to the St. Louis territory was the "no-more-anthracite-west-of-the-Mississippi" order that came in with the month of June. Over 40,000 tons were booked, with no chance of getting any. This caused a furore that was hard to down. The Chamber of Commerce held a protest meeting, but the local fuel committee explained it away on the promise of plenty of coke. Thousands of hard-coal burners were replaced by other stoves, for the coke supply did not materialize in time, and when it did the price was unreasonably high to the consumer. There were spirited contests for what little anthracite was stored. Transportation improved toward the end of the month.

In St. Louis, outside of the zone for Illinois coal, there was a continued demand for Illinois fuels. Some

moved to Nebraska in box-cars, and a little went into western Missouri on special permits. This was soon stopped when the privilege was abused through district representatives sending Carterville coal to their relatives while others who actually suffered for the lack of it went without. During all this time the mines in the Standard field were idle because of no market.

July brought some pleasant surprises. Instead of the market lagging, it picked up. To replace the 40,000 tons of hard coal orders began to come in, and it takes over two tons of Illinois coal (nearer three tons of some grades) to replace a ton of anthracite. So the domestic business resumed. A promise was made of 25,000 to 30,000 tons of coke for the remainder of the season, and the future looked brighter.

The Standard market was affected but slightly at first, but it improved as time passed. However, it was not a healthy proposition at any time during the month of July. The outside country call was good, with fine prospects, because the outlying sections could get no coal of higher grade. The steam demand was poor, and this handicapped the operators. There was some small storage of Standard coal reported, and the railroads waded in now and then when conditions were right and brought relief.

Mt. Olive Market Proves Steady

The old reliable Mt. Olive proved the steadiest of all; not an oversupply, but just enough to swing the call. The Carterville problem seemed to grow. The orders piled up and the incoming tonnage grew smaller. Many consumers were induced about this time to change from high grade coals to coals of a lower grade, which proved a help. Considerable so-called Arkansas smokeless moved in, with some Arkansas anthracite.

It was suggested at this time that too much urging for early storage might be harmful in St. Louis proper. The public was getting anxious about its coal at the end of July, and the dealers were unable to cope with the demand for prompt delivery.

In August it was much the same as in July with regard to Standard coal. Toward the end of the month it became weaker, even though the State Fuel Administrator permitted thousands of cars of this coal to be shipped to Michigan. This helped to steady the market. The Mobile & Ohio was in bad shape for the entire month. Prices for Standard coal were about the same as in July, and the domestic storage of this grade was pretty well taken care of. Steam storage was not so good.

Mt. Olive coal was the steady-going grade, with no changes from the July condition. Carterville and DuQuoin seemed to get worse. Orders kept piling up on the dealers for these fuels. The supply was getting smaller for many reasons, but principally because of decreased production. The railroads drew heavily on this field.

A survey showed that St. Louis was the best coaled city in the country for domestic, and perhaps the poorest in steam storage. No eastern coals came in and but a small tonnage of Arkansas. The latter went up $1.50 per ton, which almost made it prohibitive in St. Louis, although farther west it seemed to move. There was up to now a shortage of coke, but gashouse got easier, with little byproduct available. Country business began to pick up in August, and toward the end of the month transportation improved on almost all the roads.

The lightless day and night orders were a farce here. Mines were idle because of an overproduction of steam coal, and yet at the same time regular avenues of consumption were being eliminated. There was much sarcastic comment on the part of the public over the lightless night order and the skip-stop system. For a while these conditions threatened to create such a surplus of screenings that the price of Standard and Mt. Olive lump almost justified a higher Government price that would permit the screenings to be dumped as in Arkansas, in order to get out any lump at all. Chicago proved to be a good outlet for these cheap screenings.

Fuel Administrator Crossley at this time succeeded in getting Washington to cancel the order preventing brick and other nonessential industries in Missouri from procuring coal for storage and current needs. The Federal Fuel Administration sustained the plea of the State Fuel Administrator through C. E. Morrow, of the St. Louis Fuel Committee, and E. J. Wallace, advisor to the committee, that the basis for gashouse coke prices in the St. Louis and mid-west section should be on the rate from the Earlington, Ky., field and not from Pittsburgh. This rate was $1.70 or $1.85 under the Pittsburgh rate, and coke came down from $9.60 to $7.70 ovens at St. Louis with a refund dating back to July 8.

The market continued easy all through September on Standard domestic sizes. Steam was heavy, and screenings as usual were a drug. The railroad orders helped some, in fact these were life-savers for many mines. Retail business was off, other than for apartments and buildings, which were storing up all the the coal they could get. Mt. Olive moved along tranquilly as usual.

Situation Shows Signs of Easing Up

The Carterville situation showed some signs of easing up for the future, although little coal moved in. DuQuoin coal proved somewhat freer. Retailers began slowing up in their desire to fill every coal bin in St. Louis when the fuel committee announced that fully 75 per cent. of the domestic coal needed up to Jan. 1 was stored. Dealers began to figure out a winter of idleness if it continued that way, and eventually they found they were correct.

Country business was good in the St. Louis territory in September. Failure to get Carterville up to now begot a desire to play safe and take what was offered. This was Mt. Olive, if available; if not, Standard went. At some places in the territory steam plants that could just as well burn Standard were using Carterville, while whole communities could get neither on account of there being no Standard rates in effect to the places where Carterville was used for steam.

The new retail price on gas coke was set at $11.25 with byproduct at $13. The producers agreed to cut this to $12.50, which would be the anthracite price. The producers, however, did not keep their promise, and byproduct later became plentiful because the public would not submit to that kind of a policy. Some Arkansas anthracite—a few hundred tons—and about twice as much Arkansas smokeless came in, but no eastern fuels.

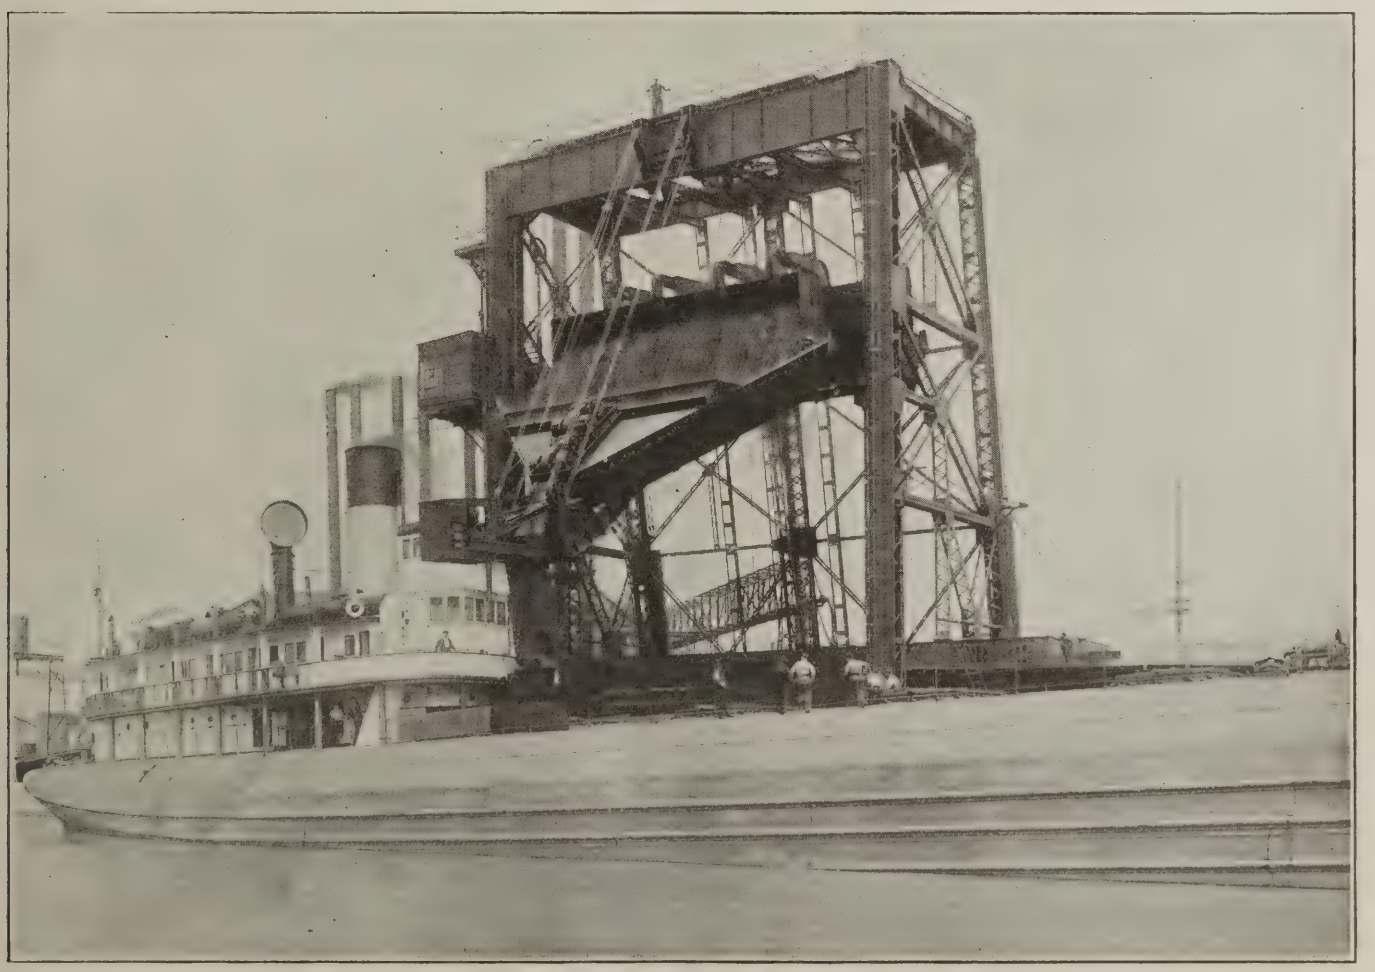
In October the shoe was on the other foot, as the operator began to worry. The market began to slump.

Standard conditions grew worse. Steam buying was light and slow. There was little done in the domestic line. Railroad business practically kept the Standard field going during October. The month was depressing, with an oversupply of all kinds of coal.

Mt. Olive fared better, but showed a weakening. There was some domestic business here, but it was railroad orders and a tonnage to the north and Canada that saved St. Louis from a broken Mt. Olive market. Even Carterville began to ease up toward the last, and the St. Louis territory began to get some. This tonnage gradually increased until at the end of the month some dealers asked that shipments be held up.

Contrary to expectations there was no cold weather in October. This was unusual and was the cause of a slowing up in the outside demand. At this time there were light shipments of Arkansas smokeless.

As November progressed conditions became still more depressing. There was a day or two of chilly weather during the latter part of the month but otherwise it was a record-breaking month for summer weather and no business. Standard mines were idle. Railroad tracks were congested and the yards were full of coal. Plants with storage stocks began to cut into them, and both wholesale and retail prices went to pieces. The latter suffered a cut of 50c. to 75c. and soon brought a like reduction on all other coals.



No call for either steam or domestic coal put the market squarely up to the railroads, who waded in splendidly for a few weeks and then laid off to use up their storage piles. Mt. Olive coal fared somewhat better than the other grades. It moved out and north with a railroad tonnage that stayed.

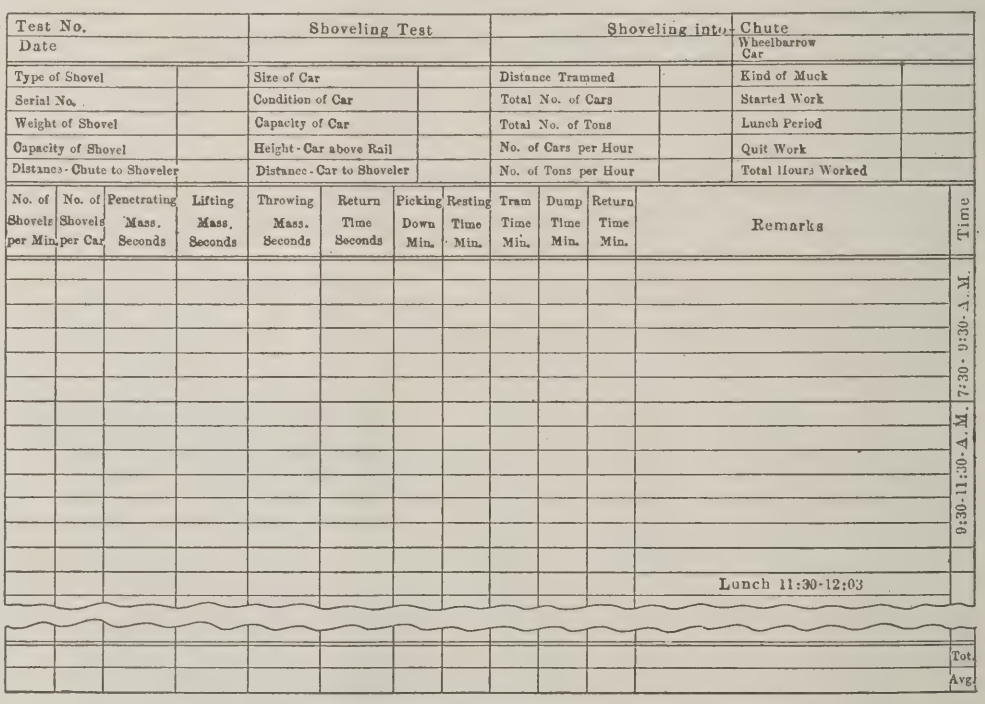
Carterville coal was virtually a drug on the market. On this grade, and also on Mt. Olive, the jobbers' margins were allowed by the operator. Standard got down to $1.40 for screenings, with $1.75 for 2-in. lump to $2 for 6-in., and these prices remained to the end of the year.

December weather conditions were remarkable, not a single cold day being registered during the entire month. It was the mildest winter since 1877. Dealers had nothing to do; domestic orders were being made for one-half and single tons. It was a standstill month.

Mines whose output came to St. Louis were idle for over a week at a time. It was usually outside business that helped them at all. The country call was slight, but it was well ahead of the city demand. Transportation, of course, became good, but the carriers still persisted in keeping unreasonable orders in effect, which only served to add to the disappointment.

The year, which had opened under such favorable auspices for the coal industry, proved a disappointment at the close. To the right thinker, the disappointment was acceptable, for it was brought about chiefly through the ending of the war. To the trade this was the one big factor, and all interested parties were glad of the outcome, regardless of its effect on the coal industry. With the coming of a new year vanished the dreams of a great united industry in this section. This will not be brought about until there is a head to each part of the industry that every member can trust.

CAR DUMPING MACHINE OF THE PITTSBURGH, BESSEMER & LAKE ERIE R.R. AT CONNEAUT, OHIO



A Study of Shoveling as Applied to Mining—I*

By G. TOWNSEND HARLEY
Tyrone, New Mexico

SYNOPSIS—*A series of tests was made to determine under what conditions a Mexican laborer would handle the greatest tonnage of muck in a given time, both underground and on the surface. Many factors influence the result, some of which are clearly set forth in this article.*

STOPING methods in which shoveling plays an important part are gradually being replaced by other and cheaper methods. But there will always be considerable shoveling done underground in stopes as well as in drifts, tunnels, winzes and shafts. At the mines of the Phelps-Dodge Corporation at Tyrone, N. M., the cost of shoveling in all stopes in 1917 amounted to 24c. per ton. In the top-slice stopes for the same period, it cost 27c. per ton, or 16 per cent. of the total cost of these stopes. The tonnage for shovelers from all stoping was 9.3 tons per man, and for top-slicing 8.2 tons per man. These stopes were not unduly hot, and there was not more than the usual amount of timber to interfere with the work of the men. The tonnages obtained per shoveler were considered low; first, because of a poor grade of Mexican labor, many of the men having come in from railroad grading camps; and second, because of a poor spacing of raises, especially in the top-slice stopes, where, in general, they were spaced 25 x 66 ft. centers. The average wage per laborer shift was $2.67 during the year. It was thought, however, that even under these conditions the men were not producing the tonnage that they should, so, with the consent of the management, the writer undertook to determine how the general efficiency of the underground shoveling could be improved. No predetermined plan for conducting these experiments was arranged, because we had no definite ideas as to the scope of the work or the number of elements into which the investigation would resolve itself, before all of its phases could be determined. We were sure, however, that any work that would thoroughly cover the ground would have to be in the nature of a systematic time study, combined with a course of instruction in correct shoveling methods and adequate and intelligent supervision of the work.

Two or three companies in the Southwest have done some work to determine the proper shovel to be used underground, but so far as is known the work has been limited to equipping certain parts of their mines with a particular type and size of shovel and thereafter watching the cost and efficiency records. In each case it seems to have been the shovel that held the 21-lb. load that gave the best results. Excepting personal communications from these companies, the only data available on scientific shoveling are contained in F. W. Taylor's book, "The Principles of Scientific Management," and D. J. Hauer's article, in *The Contractor* for Mar. 29, 1918, "A Hundred Hints for Shovelers."

FIG. 1. TIME-STUDY SHEET USED IN THE TESTS

This paper discusses and draws conclusions from several thousand time-study readings, taken both on the surface and in the mines for nearly a year. A sufficient number of readings were taken on each factor in the problem for the plotting of curves of the performances and to obtain accurate indices of the work to be expected from this class of labor. The work here described is not as complete in all of its details as we would like to have it, because we were forced to stop the work temporarily, owing to the number of men going into the national service, and our inability to get others who could make time studies. The results obtained so far, however, have been of such a startling nature that we have decided to submit them at this time, subject to future modification. It is hoped, also, that

*First installment of a paper to be presented before the February meeting of the American Institute of Mining Engineers.

a free discussion of this paper will lead to a disclosure of any errors that may have been embodied and offer some valuable suggestions for the conduct of future work.

As a first step, several weeks were spent underground making a general survey of the field and making time studies on various men, in order to see what points would need to be determined for a full consideration of the subject. The following factors are soon recognized:

1. The type, weight, size and design of shovel giving the greatest shift tonnage without too much wear and tear on the man would have to be determined. This work would also determine the point at which a shovel should be discarded as worn out.

2. A standard of comparison would be necessary if the ill effects of mine air, powder gas and smoke, temperature, humidity and poor light were to be estimated.

3. The layout and spacing of chutes would have to be studied with regard to their effect on shoveling directly into them, or loading into wheelbarrows or cars and tramming to them. This work would determine the proper distance at which shoveling into a chute should leave off and loading into a wheelbarrow or car be taken up. The information would also be of great use in planning the development of a stope.

4. Hindrances to work, such as timber standing in line of throw or closely spaced, men and supplies passing back and forth through working space, etc.

5. Manner of placing the shovelers to obtain maximum results from them, number of men in one working place, and size of working place required per man.

6. The hours of actual work and the cause and amount of delays, such as shoveler interrupted to help in other work, etc.

7. The capacity of a man for work as the day progresses.

* Specially made Test Shovel. E.P. = Eastern Pattern Scoop. W.P. = Western Pattern Scoop.

These average capacities were obtained by repeatedly shoveling a weighed pile of ore with each of the shovels and counting the number of shovel loads required to move it. Table I gives the number of cubic inches of ore in a 21-lb. load, for ore breaking to different volumes per ton; and Table II gives the sizes and types of shovels that will average up to any given content. Owing to the variety of conditions in underground shoveling, such as the material of which the shoveling platform is made, whether of wood, iron or natural bottom; the unsized material shoveled; and the amount of moisture in the ore, causing it to be sticky at times.

These average shovel capacities were found not to accord with actual practice, except over test periods of long duration; for short periods they would vary as much as $\frac{3}{4}$ lb. from the average, while single shovel loads would vary as much as 3 lb. For Burro Mountain are, the tables show that it requires a specially made shovel with a 10 x 13-in. blade to hold the 21-lb. load, or 363 cu.in. In practice, however, we are using at the present time a No. 4 square-point shovel holding 373 cu.in. and a No. 5 round-point shovel holding 340 cu.in. At this time also, a time study sheet, shown

FIGS. 11 TO 13. LIFTING AND THROWING LONG-HANDLED SHOVEL CONTENTS

Fig. 11—Shovelful has been lifted. Fig 12—Preparing to throw shovel contents; a short step has been taken in direction of throw. Fig. 13—Contents have been thrown; note ease of position as compared with Fig. 7

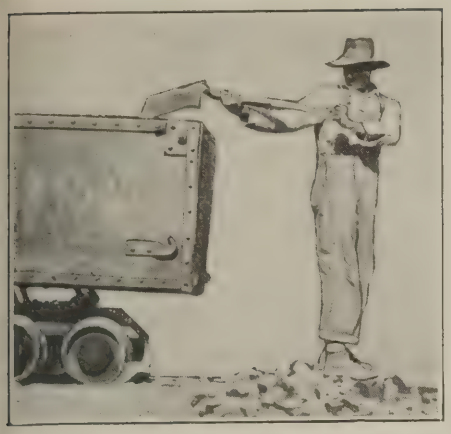

FIG. 14. CORRECT MANNER OF THROWING ORE INTO CAR
Car is only 4 ft. from top of ore pile

in Fig. 1, was developed that was used for all tests. In addition to the data placed on this sheet, an extensive log of the work was carried on. This undertook to explain, in detail, all delays, changes of work, rest periods, changes in conditions that would affect speed, high and low efficiency periods during the day, etc. Each night the study sheets and the log for the day were turned in at the office and the writer totaled, averaged and checked all readings, and entered them on special record sheets and charts in a convenient manner for comparison and study.

During the period of preliminary work, it was discovered that the work of a shoveler can be classified into the following divisions, each susceptible to comprehensive study and analysis, and to each of which can be given a definite relative time value.

Time spent actually shoveling, which may be divided into: Penetrating mass, lifting shovel contents, throwing shovel contents, and return to start of first motion.

Time spent picking down, considered as a rest.

Tramming and dumping time, with wheelbarrow or car.

Time spent resting, divided into: Definite rest periods and delays due to interferences, blasting, men and supplies passing, etc.

Time spent other than in shoveling was not counted in shoveling time. This included delays before starting to work, lunch period, quitting early at end of shift, and time spent on other work, helping machine man, timbermen, etc.

The motions listed are illustrated in Figs. 2 to 17. By studying each motion separately, it was possible to establish a standard time for each and, consequently, a standard of performance for the whole. It was possible, also, to discover which were the most tiring motions and how each was affected by length of time worked, length and distribution of rest periods, size of shovel, design of shovel, and length of throw. It was, of course, impossible to time all the motions made with any one shovelful; consequently these figures had to be obtained in rotation, each figure set down on the sheet being an average of 10 consecutive readings. For example, the day would be started by taking 10 readings of the number of shovels per minute and the average of these set down on the first line of the column of the time-study sheet. Ten readings would next be taken of the time for penetrating the mass, the average of which would be set down on the first line in the third column, and so on throughout the day. All delays and rest periods were timed and all wheelbarrow and car loads counted. As a check on the tonnage handled, a record was had of the number of shovelfuls making up a load, the average capacity of the shovel and of the wheelbarrow or car, an estimate was made of the tonnage in the original pile and, in many cases, the tonnage drawn out of the chute into which the man was shoveling or dumping the ore. At intervals during the day, a line was drawn across the time-study sheet, as in Fig. 1, and all subsequent readings were recorded below this line. This was done to watch the relative efficiency of the men at different times of day.

FIG. 15. PENETRATING MASS WITH HIGH-LIFT SHOVEL
Man not crouching as low as in Fig. 3

In order to obtain some standard of comparison for the underground work, some of the mine shovelers were brought to the surface and a record made of their work under ideal conditions; that is, with good air, good light, no timber to interfere, steady shoveling for various lengths of time, and standard lengths of throw for the muck. A platform was built on the side of the mine-

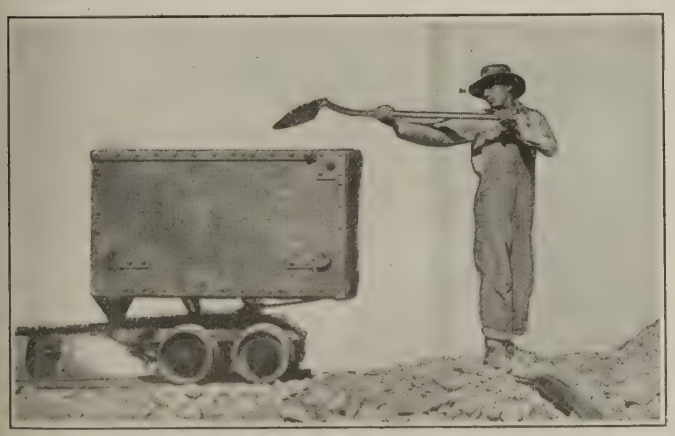

FIG. 16. CORRECT MANNER OF THROWING ORE INTO CAR WITH LONG-HANDLED SHOVEL
Car is 4 ft. from top of pile

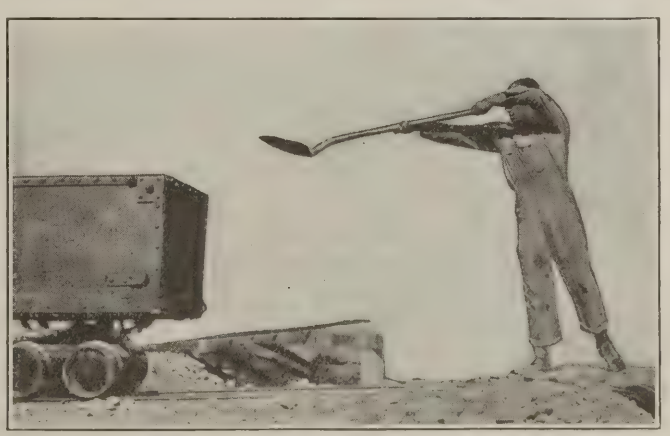

FIG. 17. SHOWING INCREASED EFFORT NECESSARY TO THROW ORE A LONG DISTANCE INTO CAR
Car is considerable distance from pile

waste dump, about 12 ft. below the year level, with a slide from the track above so arranged that no matter what quantity of muck was in the slide the toe of the pile was always in the same place on the platform and the shoveler did not have to move up as shoveling progressed. At several places on the platform trap doors were installed so as to obtain any desired length of throw into what corresponded to a chute in the mine. The muck thrown through these doors rolled down the side of the waste dump, out of the way, so that the opening was always clear. A track was laid along the side of the dump at the platform level, so that tests could be conducted in which the shoveler loaded the muck into a car, which he then had to tram a distance of about 100-ft., dump, and return to the muck pile again.

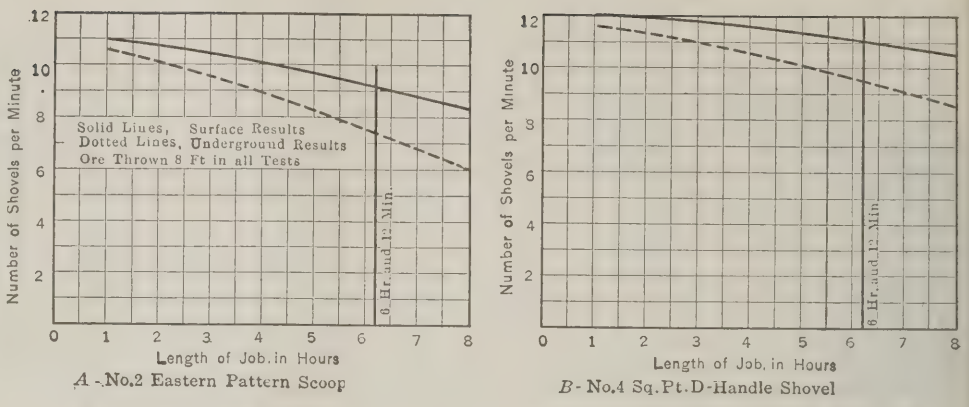

FIG. 18. EFFECT OF LENGTH OF JOB ON NUMBER OF SHOVELS PER MINUTE

In addition to obtaining the comparison standard, it was possible to form some definite conclusions, which were later checked satisfactorily under actual conditions in the mine, as to the most advantageous size, type, weight and design of shovels for general mine use, under the various conditions to be met with there. Tests were carried on for two months, three different shovelers, taken from the mines, being observed. Each of these men was warned that he had to work at his best speed, all during the job, but that he was not to overtax himself. He was told that when he became tired he was to take a few moments' rest, as it was better for him to rest at intervals than to try to work all the time, at the expense of speed and capacity. Later, we undertook to regulate the rest periods, to obtain the proper intervals at which they should occur, and their length. The results of these tests will be discussed in conjunction with the underground work.

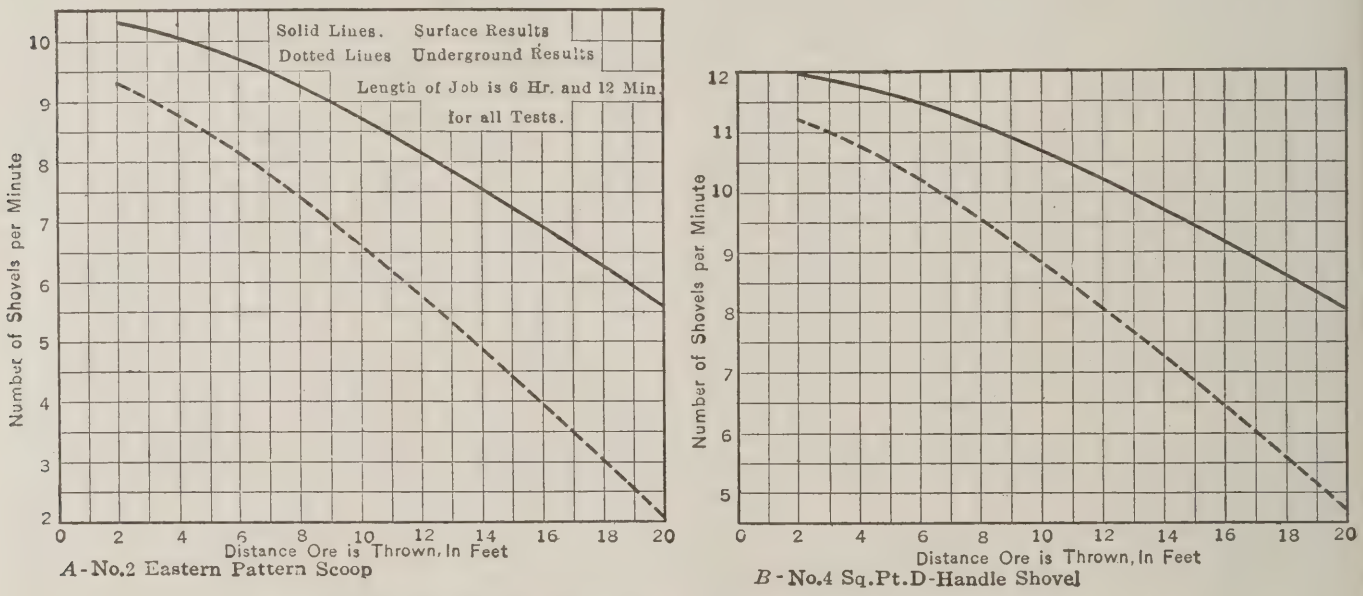

FIG. 19. EFFECT OF DISTANCE THROWN ON NUMBER OF SHOVELS PER MINUTE

All of the underground shoveling tests may be classified under one of three headings—shoveling directly

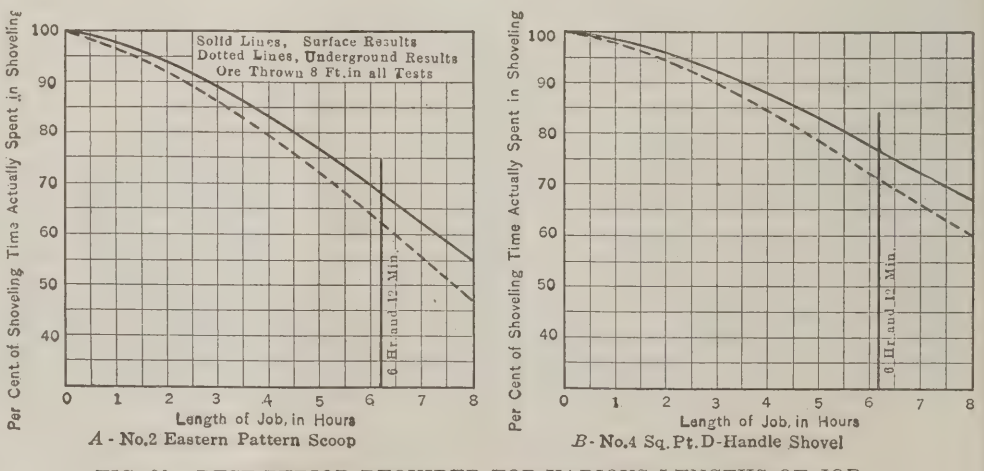

FIG. 20. REST PERIOD REQUIRED FOR VARIOUS LENGTHS OF JOB

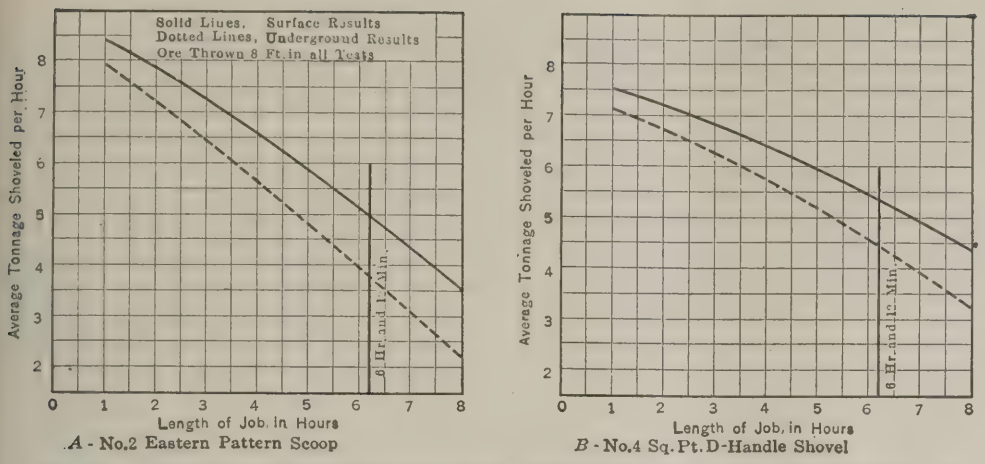

FIG. 21. AVERAGE TONNAGE SHOVELED PER HOUR FOR ANY LENGTH OF JOB

into chutes, shoveling into wheelbarrows and tramming to chutes, and shoveling into cars and tramming to chutes. Each of these series was conducted independently of the others, and was complete in itself. The men under observation worked for periods varying from 1 to 8 hours, and for each length of job they threw or trammed the muck over a wide range of distances, with various types and sizes of shovels. In all the underground tests the work was done under the actual mining conditions, with the one exception that the men were always under observation and consequently were working at a good speed for the full period of the test. In no case did the men overtax themselves, and we feel confident that all tonnages obtained and indicated on the charts are easily obtainable by a good, but not exceptional, Mexican laborer after he has been properly instructed, and under close and intelligent supervision, together with a wage paid in such a manner that he has a constant incentive to do good work.

It soon became evident that the great majority of shovels being tested were not suitable for efficient work, and although we continued to work with them to some extent, we have charted only the work of the No. 4 shovel, which handles the 21-lb. load, together with the No. 2 scoop, which was held in high esteem by many of the men in the operating department. In each of the charts of this series, Figs. 18 to 22, the results obtained during the surface tests are plotted alongside of corresponding results from underground, in order to accentuate the adverse effects of underground conditions on shoveling capacity. In Fig. 18 will be found the number of shovels per minute thrown into a chute at a distance of 8 ft. from the ore pile for jobs varying in length from 1 to 8 hours. In all of these charts, the length of job should be understood to mean the total working time, and when it is said that the length is 4 hours, the man was actually occupied at shoveling ore for 4 hours, and then his work was finished. All points on the curves are corrected averages for the time periods to which they correspond.

In connection with Fig. 18, the following facts will be noted: For all lengths of job, the number of shovels per minute is greater with the No. 4 shovel than with the No. 2 scoop. Both on the surface and underground, the speed of shoveling decreases more rapidly with the scoop than with the shovel, as the length of the job increases. A man working with a scoop underground can perform at only 72 per cent. of his speed on the surface for 8 hours, while with a No. 4 shovel, he can work at 82 per cent. of his surface speed. The percentage reduction in speed between surface and underground work is the measure, in part, of the effect of mine air, powder gas and smoke, temperature, humidity and poor light. Under the same condition of work, the difference in speed between the No. 4 shovel and the No. 2 scoop is due to the difference in the load handled. For short lengths of time, the difference in working speed between a scoop and a shovel is so small that, disregarding rest periods, the scoop is a slightly greater tonnage mover than the shovel; but for longer periods, the difference in speed is such that the shovel with its

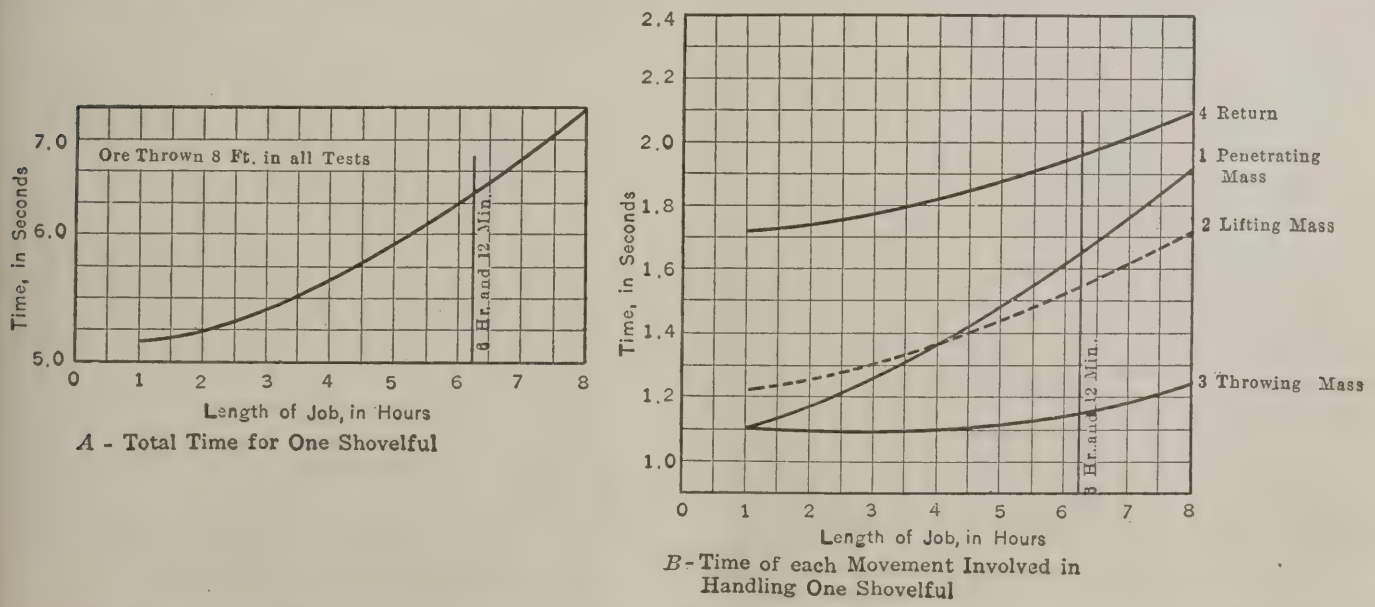

FIG. 22. SHOWING TIME CONSUMED IN HANDLING ONE SHOVELFUL OF MUCK WITH NO. 4 SHOVEL UNDERGROUND

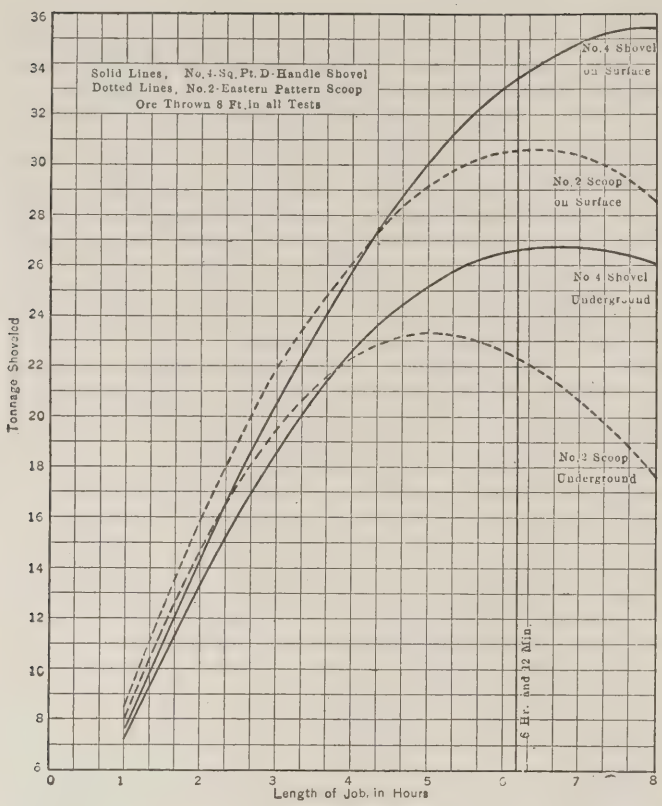

FIG. 23. COMPARISON OF WORK OF NO. 2 SCOOP AND NO. 4 SHOVEL

smaller capacity actually moves more muck than the scoop.

Fig. 19 indicates the manner in which the length of throw will affect the speed of the shoveler. These charts were worked out for a uniform length of job of 6 hours and 12 minutes, and for varying distances, as shown. The same relationship exists between the lines of these charts as on the charts of Fig. 18. The decrease in shoveling speed on the surface amounts to an average of 2.5 per cent. for every foot increase in distance thrown in the case of the scoop, and 1.8 per cent. for the No. 4 shovel. Underground, the working speed is decreased more rapidly, being respectively 4.4 per cent. and 3.2 per cent. per foot increase in throw. The rate of decrease, both on the surface and underground, is greater for the scoop than for the shovel.

To find the average shoveling speed for any length of job and for any distance that the ore has to be thrown, the number of shovels per minute for a throw of 8 ft. for the proper period, can be obtained from Fig. 18; this can be increased or diminished by the proper percentage obtained from Fig. 19, depending on whether the distance is less or greater than 8 ft. As an example, suppose that it is desired to determine how many shovels per minute a man will average, throwing a distance of 12 ft. for a length of a job of 6 hours, using a No. 4 shovel underground. Chart B, Fig. 18, shows that for 6 hours, throwing a distance of 8 ft., a man will average 9.6 shovels per minute. Chart B, Fig. 19, shows that to increase the length of throw from 8 ft. to 12 ft. diminishes the shoveling speed 15.7 per cent.; therefore for a 6-hour job, at 12 ft., the man will be expected to handle about 8.1 shovelfuls per minute.

Fig. 20 shows the amount of rest required for shoveling jobs of various lengths. Here again will be noted the same relations between lines that exist on the other charts in which times are given. The scoop again has a negative effect both on the surface and underground, causing a man to use up more time in resting than with a No. 4 shovel. The rest period, as considered here, is made up of the time consumed in delays, the time actually spent in resting, during which the man may smoke a cigarette and sit down for a few minutes, and the time used in loosening the muck pile, scraping up the dirt on the shoveling plat, or doing other light work; not actually shoveling, but closely related to it.

Over a long period it was possible to demonstrate the feasibility of accurately determining the percentage of the working day that a man will actually devote to shoveling. The working day at the Burro Mountain mines is 8 hours, one-half hour of which is given up to the lunch period, leaving 7½ hours as the total possible working time. It was found that of this 7½ hours, the man actually worked at shoveling for 82.5 per cent. of the time, or for 6 hours and 12 minutes, and on all the charts involving time, this particular length of job has been designated by a special line. The remainder of the possible working time, or 17.5 per cent., is spent on other work, quitting early for lunch or to leave the mine or commencing to work late at beginning of the shift or after lunch. Observations of this character

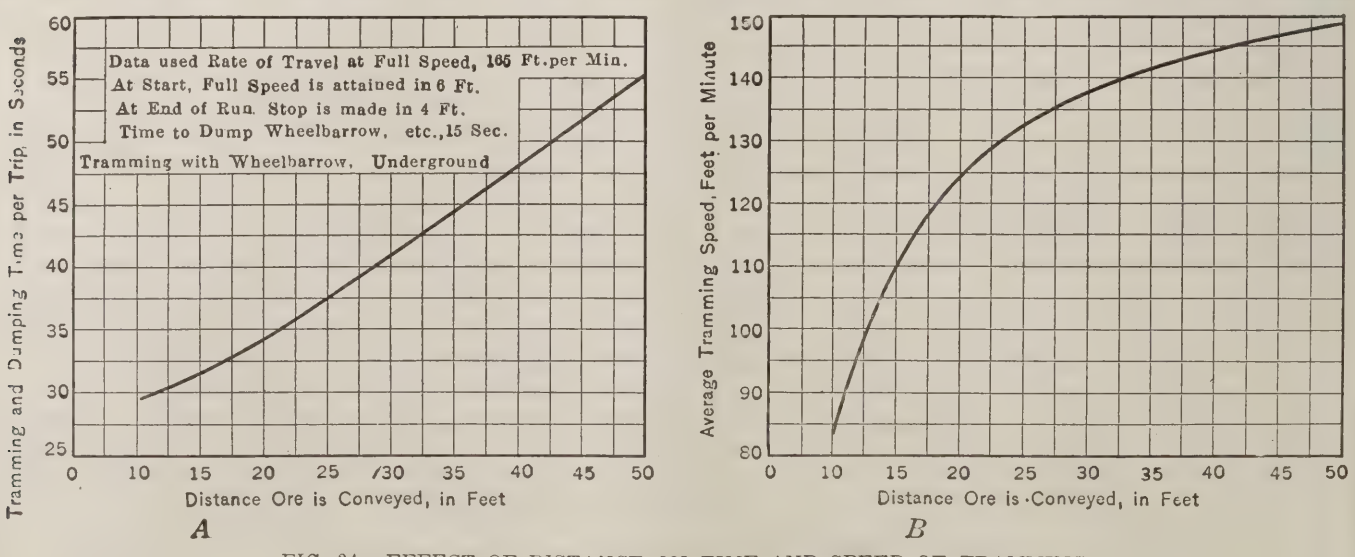

FIG. 24. EFFECT OF DISTANCE ON TIME AND SPEED OF TRAMMING

were gathered by some of the shift bosses, on several hundred-man shifts, and it is surprising how little the figures obtained by each have varied from the average finally obtained.

Fig. 21 gives the average tonnage per hour to be expected of a man throwing the muck a distance of 8 ft. over any period of time; and Fig. 23 gives the total tonnage shoveled for any period, over the same distance. These graphs are corrected to agree with Figs. 18, 19 and 20, but as an illustration of how closely the actual results obtained agree with the charts, the following figures are presented: For a job lasting 5 hours and 30 minutes, with a No. 4 shovel underground, according to Fig. 23, a man would be expected to shovel 26.0 tons a distance of 8 ft. Five representative tests actually gave the following tonnages under average conditions:

Length of job 5 hours and 40 minutes, tonnage.....	28.0
Length of job 5 hours and 10 minutes, tonnage.....	23.0
Length of job 5 hours and 25 minutes, tonnage.....	26.0
Length of job 5 hours and 50 minutes, tonnage.....	34.0
Length of job 5 hours and 30 minutes, tonnage.....	25.0
Average, 5 hours and 30 minutes, tonnage average.....	27.4

Fig. 22 shows how the time of shoveling one shovelful of ore is influenced by the length of the job, with the length of throw remaining constant. In Chart B, the total time of handling one shovelful of muck has been divided into its component movements. The lines representing the work of penetrating mass, lifting shovelful, and return, show a constant increase as the length of job increases. The actual increase in the time of each movement is not due so much, it is thought, to a decrease in the speed of making the move, which probably is fairly constant, as it is to an ever-increasing period of rest taken at the beginning and end of each movement, which, however, was too short to be accurately timed. Throwing the mass in the shovel is not influenced as much as the other moves, as the muck must be thrown along a definite path, which is limited to distance and height, and hence a constant speed must be maintained to carry it over.

The reader will be well repaid by a careful study of Fig. 23, and the following points should be noted:

1. The difference in tonnage handled by the same shovel, on the surface and underground, for any length of job, is the measure of the bad effects of underground conditions. For a job of 6 hours and 12 minutes, with a No. 4 shovel, the underground work is 20.5 per cent. less than on the surface.

2. The difference between the amounts shoveled with the No. 2 scoop and the No. 4 shovel, under same conditions, is the measure of the effect of the difference in load handled by the man.

3. Each line on this chart shows a peak at some particular length of job, and the total tonnage shoveled for

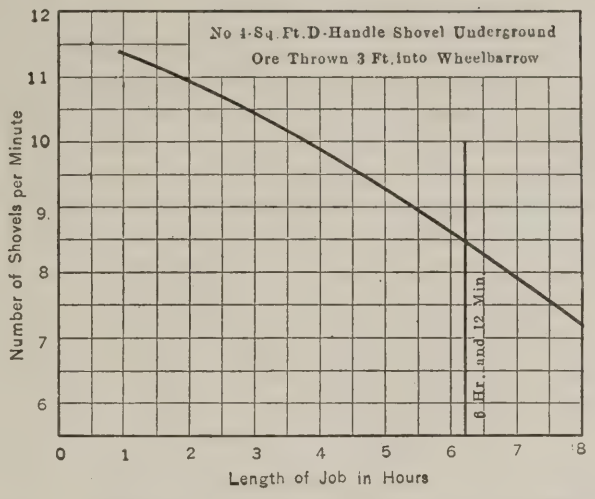

FIG. 25. EFFECT OF LENGTH OF JOB ON NUMBER OF SHOVELS PER MINUTE

any greater period than this is actually less. The point at which this peak occurs should be termed the "economic shoveling day," and a company should not require its men to work at shoveling any longer than this, except in emergency cases.

4. The presence of this peak accords with the experience of many superintendents and managers, who state that their men do more work in an 8-hour day, than they did on an old 10-hour basis.

5. The "economic shoveling day" is about 6⅓ hours, with a No. 2 scoop on the surface, and 5⅓ hours underground. With a No. 4 shovel, on the surface 8 hours is about the proper length of day, while underground 6⅔ hours seems to be about correct. As the men actually shovel only 6⅓ hours per day on an average and as their other work is generally of a light nature, the 8-hour day with the correctly proportioned shovel is probably the best; but with a scoop it is certainly too long.

6. For work on the surface, on jobs lasting longer than 4⅔ hours, the No. 4 shovel is superior to the scoop. Underground the No. 4 shovel demonstrates its superi-

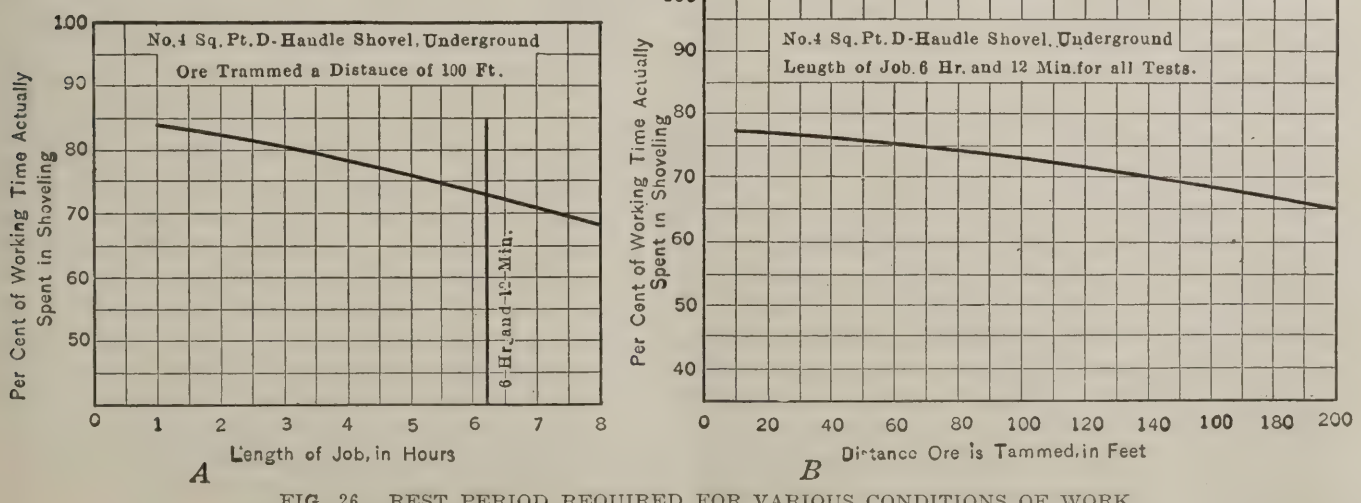

FIG. 26. REST PERIOD REQUIRED FOR VARIOUS CONDITIONS OF WORK

ority for jobs longer than 3⅔ hours. The scoop then may be considered as a task shovel for short-time jobs, but even here, its value is only slightly greater than the No. 4 shovel, besides tiring the man so that he is unfit for other work when the shoveling task is finished. There is also the additional danger of having some men continually trying to use the scoop for the full shift, thinking that the amount of work (and hence the amount of pay in the case of contract and bonus systems) is greater as the size of the shovel increases.

The following formulas show the manner in which use is made of the figures presented in the preceding diagrams:

Let W = Weight of load on shovel, in pounds;
N = Number of shovels per minute, Figs. 18 and 19;
P = Per cent. of time actually shoveling, Fig. 20;
L = Length of job, in minutes;
T = Total tonnage shoveled;
n = Number of shovels per minute for an 8-ft. throw, Fig. 18;
p = Per cent. increase or decrease due to various lengths of throw, Fig. 19.

Then

$$\frac{W \times N \times P \times L}{2000} = T \qquad n = N(1.00 \pm p)$$

Example 1.—What will be the total tonnage handled, using a 21-lb.-load shovel, throwing the ore 8 ft., underground, for a job of 5 hours duration? Chart B, Fig. 18, shows that for 5 hours a man with average 10.1 shovels per minute, and Chart B, Fig. 20, shows that he will actually shovel 79 per cent. of the 5 hour period, therefore:

$$\frac{21 \times 10.1 \times 0.79 \times 300}{2000} = 25.1 \text{ tons}$$

Example 2.—What will be the total tonnage handled, using a 21-lb. load shovel, throwing the ore 15 ft. underground, for a job of 6 hours duration? Chart B, Fig. 18, shows that for 6 hours a man will throw a distance of 8 ft. at the rate of 9.6 shovels per minute. Chart B, Fig. 19, shows that increasing the distance to 15 ft. reduces the capacity by 27.4 per cent., therefore:

$$N = n\,(1.00 \pm p) = 9.6\,(1.00 - 0.274) = 7;$$

hence,

$$\frac{21 \times 7.0 \times 0.79 \times 360}{2000} = 19.3 \text{ tons}$$

Shoveling Into a Wheelbarrow

The charts presented in the series, Figs. 25 to 27, follow as closely as possible the series just discussed, but offer only the results obtained with the No. 4 D-handle shovel. It was soon discovered that a throw of 3 ft. to the wheelbarrow gave the best results so far as number of shovels per minute and rest periods required were concerned, and in all subsequent work the ore was thrown into the wheelbarrow from this distance. It will be noted that, in Fig. 25, for any length of job, the number of shovels per minute is less than when throwing 8 ft. into a chute; this is due to the fact that the shoveler must place each shovelful carefully to keep the wheelbarrow from spilling its contents and to make it ride easily.

Chart A, Fig. 24, shows the length of time consumed in tramming and dumping a wheelbarrow over any distance, and Chart B shows the average tramming speed developed for any distance. For this chart, careful determinations were made of the distance in which it takes a man to acquire full speed and the distance in which, after having attained full speed, he can make his stop. The full-speed rate of travel in stopes will average 165 ft. per minute. The wheelbarrow in use is the No. 7, which holds 3 cu.ft. and stands 21 in. above the floor at the point of maximum height. The maximum load in a wheelbarrow should be about 300 lb. as larger loads are too exhausting, and lighter loads consume too much time in tramming and dumping.

Chart A, Fig. 26, shows the per cent. of time a man will work during any given working period, the length of tram in each case being 20 ft. The rest period is practically a constant proportion of any length of job, as that part of the tramming time in which the man brings the empty wheelbarrow back to the ore pile is virtually a rest period. For long trams, the work of tramming the loaded barrow is so heavy that a greater

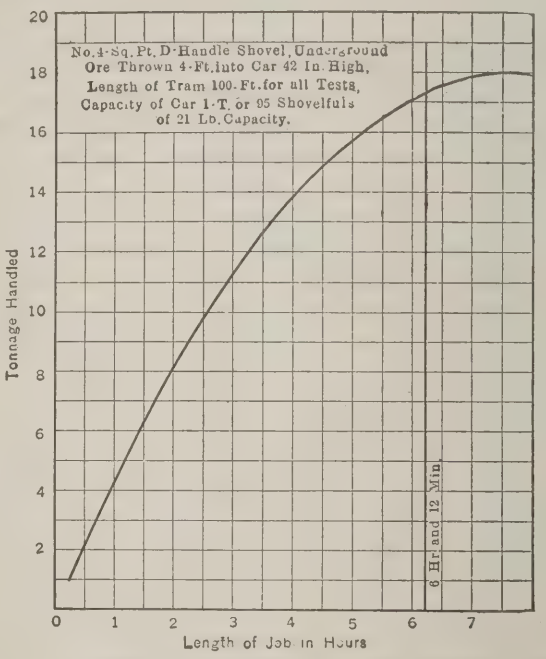

FIG. 27. SHOWING CAPACITY OF A SHOVELER USING A WHEELBARROW FOR VARIOUS JOBS

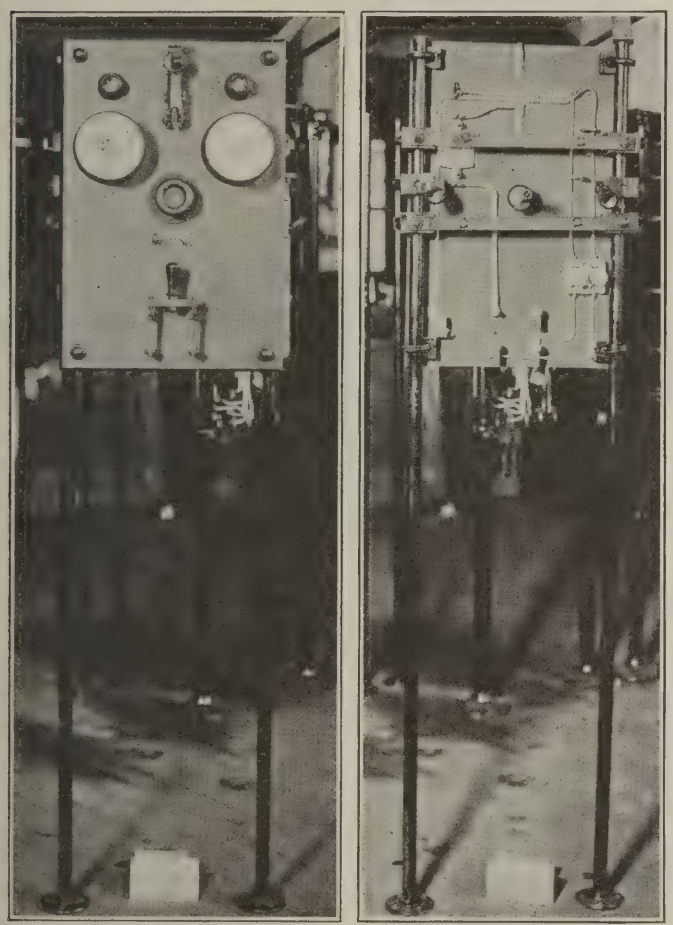
rest is required than is obtained on the return, and Chart B shows how the rest period increases for a constant length of job, as the length of tram increases.

Fig. 27 shows the tonnage to be expected of a man, based on Figs. 24 to 26, for any length of job, the length of tram being constant at 20 ft. This chart shows that the shoveler has not quite reached his maximum capacity at the end of 8 hours. Two reasons are advanced for this: (1) As long as a man can throw the ore into a chute, he has a fairly direct throw from the ore pile to the chute, and with a car he has a definite path to traverse each trip. With a wheelbarrow, however, the direction and length of tram are constantly varying, as is also the amount of interference from other trammers, timbermen, machine men, etc. The retarding influence of these factors increases as the length of the tram increases. (2) The sequence of operations, shoveling, tramming, dumping, etc., is of such short duration and changes so often from one to the other that it is hard to keep up any pace that may be set and probably an unnecessary amount of rest is indulged in for all periods.



(To be concluded)

There are some indications that volatile combustible containing a high percentage of oxygen is harder to burn than one containing little oxygen. Whether the difficulty in burning it is due to the oxygen content or to some other chemical property can not be stated definitely.—*Bureau of Mines Bulletin No. 135.*

New Apparatus and Equipment

Ready-to-Wear Switchboards for Small Installations

The switchboards shown in the accompanying illustration, known as the Westinghouse "ready-to-wear" type, are each suitable for the control of a direct-current generator and three lighting circuits. They are particularly adapted to the smaller installations. One advantageous feature of this type of switchboard is that it can be placed in operation by simply connecting the leads from the generator and feeder circuits to the terminals provided for that purpose. This is in marked contrast with the expense entailed in the purchase of meters, switches, circuit-breakers, slate slabs, framework and the work of designing and assembling the complete panel on the job.

TWO VIEWS OF THE "READY-TO-WEAR" SWITCHBOARD

The installation of the old types of switchboard involved much detail work. First of all each piece of apparatus had to be ordered with careful consideration given to the type and capacity. Drilling templets of each must be secured and a considerable sum must be allowed to cover investment in machines and tools for drilling the slate and bending the copper strap connections. Finally, when the panel was built up and installed, it might operate and it may look pretty good, but one could never be absolutely certain of this from the start.

The accompanying illustration is typical of the types K.D. and J.D. panels, both of which are suitable for 125 and 250 volts in capacity up to 600 amp. They are manufactured by the Westinghouse Electric and Manufacturing Co., of East Pittsburgh, Penn. Both these types of panels permit a choice in the number and capacity of feeder circuits.

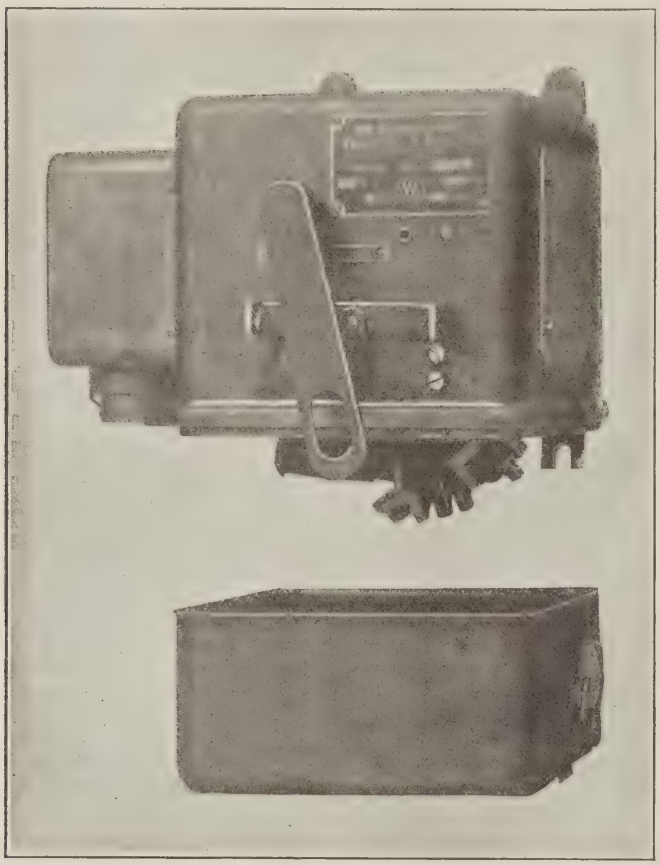
Flexible Quick-Make and Quick-Break Motor-Starting Switch

One of the new pieces of equipment brought out by the Westinghouse Electric and Manufacturing Co. during the past year is an interesting starting switch. This switch is designed for use where squirrel-cage motors are started with a full line voltage. It is known as the quick-make (and quick-break) starting switch, type 816. Its characteristics are 10 to 100 amp., 25 hp. maximum, three-phase, 220, 440 and 550 volts.

This switch is extremely flexible in application. In addition to being a motor starting switch, it can also be used to control feeder circuits; it may be supplied in any of the following combinations, each having the "quick-make and quick-break" feature, for either hand or shipper-rod operation: (a) Nonautomatic switch, (b) switch with low-voltage protection, (c) switch with inverse time element overload protection, (d) full automatic switch with low-voltage and inverse time element overload protection.

The switch is especially suitable for shipper-rod operation on account of the positive action of the contacts. It is impossible for the operator to retard the motion of the contacts after they have started to close—here can be no "teasing" of the contacts. Workmen who are accustomed to starting machines from line shafting by means of shifting belts have no confusing details to learn. They can start the motor-driven machine with the same starting motion they use in shifting belts.

The contacts are opened and closed in oil, thus effectually suppressing arcing. The contact is made or broken so quickly that the eye cannot follow the motion. A rolling action confines the arc to the tips of the contacts and prevents pitting or roughening of the seating parts where final contact is made. A strong spring holds the contacts firmly in the closed position. These features result in greatly prolonged life for the contacts.



Drawn-steel construction is employed, giving maximum strength with light weight, and assuring uniformity and interchangeability when new parts are needed for replacement or repairs. The oil tank is supported by snap ring-latches. Removal of the tank clearly exposes the contacts and makes them easily accessible. When necessary to replace contacts each may be removed by taking out a single screw.

Contacts and contact supports are of the same construction used for Westinghouse Type A auto-starters and magnetic contactors. This minimizes the number of spare parts that should be carried.

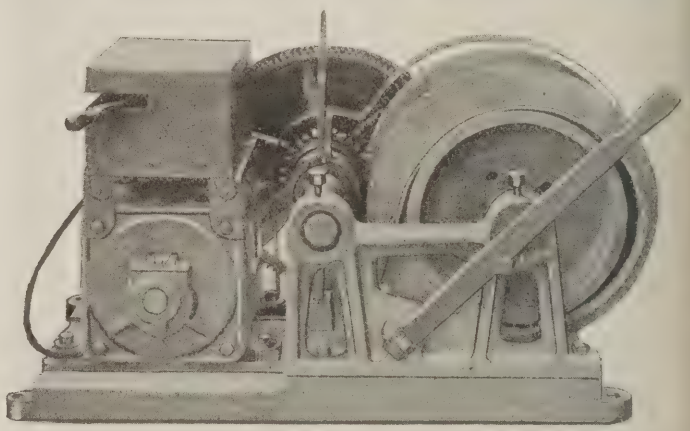
These starting switches are dust-proof. Openings are provided for conduit wiring into the top of the case; terminals for connecting motor and line wires are accessible when the cover at the top of starter is removed.

Micarta insulation is used throughout. Overload and low-voltage attachments may be added with no change to the switch mechanism, as the toggle trip is common to all combinations of this switch.

The low-voltage protection not only opens the contacts on failure of power, but makes it impossible to close

STARTING SWITCH AND REMOVABLE COVER

them again until a return of voltage. Since the low-voltage coil is connected in the line circuit continuously, means have been provided to close the armature of the low-voltage circuit when the switch is in the "off" position, thereby giving protection to the coil and preventing burn-outs. A safety stop may be provided by connecting one or more push buttons in series with the low-voltage coil.



The overload relay is the same as that used on Westinghouse Type A auto-starters. It has the inverse time element feature and is equipped with a regulating device, adjustment of which controls the degree and duration of the overload possible on a motor or feeder circuit. This adjustment can be made without opening the switch cover.

The hand reset is an additional safety feature which makes it necessary to set the mechanism before the switch contacts can be closed. Whether the contacts have been opened through the operation of the low-voltage coil, the overload relay, or by moving the switch handle to the "off" position, it is impossible to close them again until the switch handle has been moved to the "reset" position. Thus protection is afforded workmen and valuable machinery which might be injured by accidental starting of the motor.

New Room Hoist Has Three-Jawed Clutch Instead of Sliding Pinion

The Flood City Manufacturing Co. will shortly place upon the market an improved type of room hoist, facilities for the manufacture of these machines having been about completed. These machines will be built in 3, 5, and 10-hp. capacity. All gears will be cut, the main gear being securely bolted to the hoist drum. This construction insures a certain economy since if, say, the gear is broken or its teeth stripped, it is unnecessary to buy a complete gear and drum, as would be the case if these parts were cast integral.

The bearings of this machine are equipped with interchangeable bronze bushings—that is, one size of

IMPROVED TYPE OF ROOM HOIST

bushing will fit any bearing on the machine. This reduces the number of spares necessarily carried.

An important feature of this hoist is the substitution of a three-jawed tapered clutch in lieu of a sliding pinion, thus obviating the liability of stripping gears when inserting the clutch while the motor is in operation or the current is turned on.

The machines are compact and may be moved easily from place to place about the mine. Equipped with a 5-hp. G.E. motor, one of these hoists will coil 300 ft. of ½-in. rope upon its drum and, if necessary, it may be designed to accommodate greater lengths. With the motor operating at a speed of 910 r.p.m., the average rope speed is 140 ft. per minute, while a rope pull of 1200 lb. is developed.

Allowing a car resistance of 30 lb. per ton, this 5-hp. hoist will handle the following loads:

Level	40 tons
1 per cent. grade	24 tons
2 per cent. grade	17 tons
3 per cent. grade	13 tons
4 per cent. grade	11 tons
5 per cent. grade	9½ tons
6 per cent. grade	8 tons
10 per cent. grade	6 tons
15 per cent. grade	4 tons

The manufacturers of this machine have had a number of them in operation in various bituminous mines, and the reports thus far received concerning their durability and utility are decidedly favorable.

Fuel Administration Activities Now a Thing of the Past

The large Fuel Administration building is almost deserted. Cyrus Garnsey, the assistant fuel administrator, continues to observe regular office hours each day, as do some of the heads of bureaus. The bustle, which was once so characteristic throughout the extensive structure, is gone. The outer offices, which for more that a year were crowded all day long with operators and others interested in the industry, waiting to present their particular cases, rarely are used now. There is no congestion of callers. Such little work as there is to be done generally is performed in a few hours each day, but it is mandatory until the actual signing of peace to continue to maintain the skeleton of the organization.

Preparations Almost Completed for Lignite Treatment Investigations

Plans are being completed by the Bureau of Mines to take up promptly the lignite investigation for which Congress just has authorized the expenditure of $100,000. A survey is being made to determine the location of a plant at a point where the chances of success are greatest. It is practically certain, however, that the plant will be located in the Texas or the North Dakota field. Other deposits of lignite are obviously less suited for experimental purposes.

Only incidental attention is to be given the secondary products of the beneficiated lignite. All the major efforts are to be concentrated on obtaining a solid fuel and a gas fuel. It is realized that once it is demonstrated that lignite is susceptible to treatment which will produce a desirable fuel a a cost permitting of profit for private enterprise, the principal purpose of the investigation will have been accomplished. The matter of developing byproducts would go ahead rapidly once a profitable industry had been established.

It is the object to gather together at a single small demonstration plant those elements that have apparently been successful in the work that has already been done in efforts to utilize lignite. Care will be taken not to dilute the effort by extending it beyond the plant which it is expected to operate.

The work will be under the general supervision of O. P. Hood, the chief mechanical engineer of the Bureau of Mines, and under the immediate charge of S. M. Darling.

Former Railroad Head Recounts Difficulties of Handling Coal and Coke

Reviewing the work of the operating division of the Railroad Administration for the year 1918, W. G. McAdoo makes the following reference to the handling of coal and coke:

One of the heaviest tasks for the railroads during the past year has been in providing necessary transportation for fuel. This has only been accomplished by effective cooperation between the Fuel Administration and the Railroad Administration. It has been necessary to adopt extraordinary measures, and these as a rule have been cheerfully met by shippers, whose rights were at times very considerably affected. Foremost among these measures was the joint action of the two administrations in zoning the distribution of bituminous coal, the purpose being to avoid waste of transportation by prohibiting unduly long hauls to destinations which could otherwise be served and especially where such prohibition avoided the cross hauling theretofore prevailing to a considerable degree. The effect of this zoning has been to assign to each of the producing districts a certain fixed area within which to market its coal, any shipments outside of this area to be made only by permit of the Fuel Administration.

Another factor which worked advantageously in the interest of fuel production was the establishment of the Eastern Railroads Coal Car Pool for handling the coal cars owned by railroads in the eastern section of the country. This pool was created just prior to Federal control, but its administration since Jan. 1, 1918, has been under the direction of the car service section. This method of handling coal cars has some objections, but unquestionably has been very helpful in providing an increased car supply for the production of coal.

Two of the individual coal problems of the country are those of supplying the coal needs of New England and the Northwestern States, the latter from the upper lake docks. The New England movement must of necessity be handled largely by ocean, and this was made difficult in the early part of the year by the lack of shipping. By coöperation with the Shipping Board this difficulty was overcome and by the end of September the New England program, both all-rail and ocean, was so far met that the administrator for that district was unable to absorb coal as rapidly as it was being shipped, and toward the end of October requirements for the year were reduced. The coal for the Northwest must of necessity be handled during the season of open navigation on the Great Lakes, and the program of the Fuel Administration this year has been fully accomplished with less demand for equipment than ever before and practically no congestion of movement.

The foundation of successful operation in the steel industry lies in an adequate supply of coke, byproduct coal and steam coal. Every effort had been made during the year to maintain adequate supply of these fuels at such plants, and it is a matter of record at the War Industries Board that practically all of the transportation needs of coke, byproduct coal, and fuel coal for the steel industries have been promptly and adequately met.

A step of much importance was taken by the establishment of uniform rules for rating of coal mines by which car supply is directed. These were made effective as of Oct. 10, 1918. Previously roads were using different methods and with varying interpretations. On the uniform basis which now obtains a more equitable distribution of cars as between districts, railroads, and mines is possible than heretofore.

A factor which has an important bearing on the question of coal-car supply is the extent to which this type of equipment is used in handling stone, sand, and gravel for construction and road-building purposes, and curtailment of such noncoal use has been necessary. Cheerful coöperation and assistance has been received from all shippers thus adversely affected.

Senate Manufacturing Committee Has Given Up Anthracite Investigation

Temporarily the Senate Manufacturing Committee has given up the investigation of the anthracite coal situation, though Senator Vardaman is in receipt of many telegrams saying that the temporary suspension of operations in the hard coal industry was unwarranted and unjustified.

Senator Vardaman proposes to make a quiet investigation of his own, and if he finds any truth in the accusations he intends to call those responsible to account. Some of these telegrams contain the most absurd statements imaginable, such as there is plenty of empty cars; that the lull in the coal trade is but temporary; that it is the evident intention of the coal companies to continue the scarcity in order to maintain the present prices, and that the coal companies should make every effort to continue operations, so as to avoid unemployment.

Senator Vardaman would have it understood that he is not through with the other investigation either. He proposes to call in the immediate future several independent operators, some miners and a few coal dealers. He could not say just when the hearing would begin, but he thought it would be in the near future.

Railroads Carry Out Less Than Half Their Program for Improvement

Less than half of the Railroad Administration's program for improvement of the roads last year was carried out. Of the $1,218,960,000 authorized capital expenditures for leading lines only $573,334,000 was spent, according to an administration report, including an estimate for December.

For additions and betterments to tracks and property $265,931,000 was spent, and for cars and locomotives $289,388,000. Of the latter amount the railroad companies individually spent $171,872,000 and the Railroad Administration $117,516,000. Only $18,000,000 was expended on new lines and extensions.

Among the larger capital expenditure items by individual railroads were the following: Pennsylvania lines east, $54,037,000; Pennsylvania lines west, $11,765,000; New York Central, $38,421,000; Santa Fé, $22,385,000; Illinois Central, $24,830,000.

A coöperative arrangement has been made between the Geological Survey and C. A. Allen, the state mine inspector of Utah, for uniform collection of coal figures and for the sending out of joint questionnaires.

Research Graduate Assistantships at University of Illinois

To assist in the conduct of engineering research and to extend and strengthen the field of its graduate work in engineering, the University of Illinois maintains fourteen Research Graduate Assistantships in the Engineering Experiment Station. Two other such assistantships have been established under the patronage of the Illinois Gas Association. These assistantships, for each of which there is an annual stipend of $500 and freedom from all fees except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics or applied chemistry.

An appointment to the position of Research Graduate Assistant is made and must be accepted for two consecutive collegiate years, at the expiration of which period, if all requirements have been met, the degree of Master of Science will be conferred. Not more than half of the time of a Research Graduate Assistant is required in connection with the work of the department to which he is assigned, the remainder being available for graduate study.

Nominations to these positions, accompanied by assignments to special departments of the Engineering Experiment Station, are made from applications received by the Director of the Station each year not later than the first day of March. The nominations are made by the Executive Staff of the Station, subject to the approval of the President of the University. Nominations are based upon the character, scholastic attainments, and promise of success in the principal line of study or research to which the candidate proposes to devote himself. Preference is given those applicants who have had some practical engineering experience following the completion of their undergraduate work. Appointments are made in the spring, and they become effective the first day of the following September. Vacancies may be filled by similar nominations and appointments at other times.

The Engineering Experiment Station, an organization within the College of Engineering, was established in 1903 for the purpose of conducting investigations in the various branches of engineering, and for the study of problems of importance to engineers and to the manufacturing and industrial interests of the State of Illinois. Research work and graduate study may be undertaken in architecture, architectural engineering, ceramic engineering, chemistry, civil engineering, electrical engineering, mechanical engineering, mining engineering, municipal and sanitary engineering, physics, railway engineering and theoretical and applied mechanics.

The work of the Engineering Experiment Station is closely related to that of the College of Engineering, and the Heads of Departments in the College constitute the Executive Staff of the Station. Investigations are carried on by members of the Station staff and also by members of the instructional staff of the College of Engineering.

Additional information may be obtained by addressing the director of the Engineering Experiment Station of the University of Illinois, at Urbana, Illinois.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

At length the official result of the election of Dec. 10, 1918, is received, the international tellers having reached a final tally. Frank J. Hayes is reëlected president with 114,355 votes as against 88,507½ cast for John H. Walker. The other offices voted for with the votes recorded are as follows: For vice president — John L. Lewis, 131,798½; Thomas Kennedy, 66,458. For secretary-treasurer—William Green, 144,642; J. L. Sims, 50,336. It will be seen that both Lewis and Green are reëlected.

The time for new contracts is when the war comes to an end or on Apr. 1, 1920, should peace not be declared by that time. Unfortunately the New River and Winding Gulf mine workers want a new scale Apr. 1, 1919, and they advocate a conference during February and March. The old contract undoubtedly requires a meeting 60 days before renewal, but the new contract, being based on a date not known in advance, it is hard to see how a conference can be held, except fortuitously, even approximately 60 days before that date.

The operators are willing to go on paying the present wage rates and think that with the market as it is the mine worker should be satisfied and he certainly should. The decisions of Special Umpire Allison O. Smith of the United States Fuel Administration, as just reported, have all been favorable to the mine workers, so they have not even this cause for dissatisfaction.

Union Cannot Ask Disposition of Fund Not Contemplated by Testator

An old fund, established 40 years ago by Franklin B. McGowan, of the Philadelphia & Reading Coal and Iron Co., for the benefit of employees of that company, ceased operation when the compensation law came into effect. The United Mine Workers of America, District No. 9, want it reëstablished and made operative for the benefit of orphans all over the district.

As this is contrary to the wish and intention of the testator it is not unnatural that the trustees, who would be liable for a breach of trust, declare that they are not disposed to grant what is asked of them. President James Matthews, of District No. 9, and other officials of the same district, fully recognize, apparently, the justice of the statement of the trustees. They understand that, while the trustees would be glad to use the money to alleviate the sufferings of the orphans of the anthracite fields, particularly in District No. 9, or to apply it in part on the expense of building the Locust Mountain Hospital, now being constructed for the treatment and care of men injured in the mines, they cannot make any such provision, for those thus benefited would only in part be the parties in interest.

The trustees pointed out that only those who contributed to the fund were such rightful participants and that any individual member of the company who had paid dues until the fund was discontinued could file objections and bring the trustees and company into court and demand their share of the fund if the trustees and the company gave the money for the purpose requested by the union.

In the course of the discussion between the union officials and the trustees it developed that there was one point of unanimity. They did not at first agree on the purpose to which the fund should be directed, but they all believed the fund should be reëstablished in some shape or other. The company and trustees propose that a form be inserted in the pay envelopes of each employee of the company for the first pay period in February, a signature on which will serve as a request of the signer that the operation of the fund be reëstablished. Mr. Matthews gives this plan his indorsement, and on Jan. 21 he and his coadjutors issued a statement to all the men urging them to sign in favor of the proposition as it will give them and their dependents added protection. The fund will not relieve the company in any way from the past, present or future obligations resting on it under the state Workmen's Compensation Law.

The fund will pay $300 in case of death at the mines by accident, and smaller amounts will be paid those who are incapacitated while working in or about the mines. A sum of from 25c. to 50c. will be deducted from the monthly pay of each employee. The trustees are W. J. Richards, president of the Philadelphia & Reading Coal and Iron Co.; W. D. Pollard, president, Safe Deposit Bank, Pottsville; and former Judge O. P. Bechtel, of Pottsville.

West Virginia Miners Oppose Price War

A plea for coöperation between miners and operators was made a few days ago by F. C. Keeney, president of District 17, United Mine Workers. In it he stated emphatically that his organization would not countenance "cutthroat" competition and the resulting reduction in wages to miners. His statement follows:

"There are certain operators, in the Clarksburg, Fairmont and Morgantown coal regions, asking their employees to accept a reduction in wages, saying that, if the mine workers would accept this reduction, it would enable the operators to get in the market, and furnish the miners steady work. Operators of the type just mentioned are to the fair operators who want to maintain the present prices what a nonunion miner is to the union miner.

"The mine workers recognize, in years that have gone by, that the operators of West Virginia were able to stay in business only by a very small margin, and in many instances bankruptcy was the result of the 'cutthroat' competition. The operators were forced to compel the miners to accept a wage that afforded a mere existence. But since the world war broke out and the United States Government became the determining factor in that great struggle for human rights, the coal industry for the first time in its history has been enabled to get proper recognition.

"The United States Fuel Administration fixed a selling price for coal that allowed the operators a fair profit, while it enabled them to pay the miners a living wage. After this experience it is almost inconceivable that certain operators should want to resort to the chaotic condition of the past. But seeing that certain operators are taking this position, we want the miners' position understood. The United Mine Workers of America will resent with all the force at its command any attempt of the operators to reduce wages.

"The miners want the coöperation of the coal operators and must have it in order to stabilize the coal industry. It is the basic industry of the nation and should have first consideration from the American public. We know that a great many of the coal operators are doing everything in their power to maintain such a selling price for coal as will enable them to give a living wage to their employees.

"We feel that the coal operators who are attempting to unstabilize the coal industry should not be given any consideration at the hands of the United Mine Workers of America, and they will not receive any consideration so far as I am concerned. It is an age of getting together and coöperation, and one in which we all recognize each other's rights; so we may just as well accept now the conditions as they are, as try to amend them and finally accept them later."

EDITORIALS

An Overdose of Reconstruction.

THE United States has a case of nerves. It has been worrying over much about its condition. A great congress of business doctors was called by the United States Chamber of Commerce, and it proceeded to tell Uncle Sam that he had eaten too much, devoured too many indigestible things, and was faced by too much of similar fare that would surely kill him if he attempt to consume it. The doctors assured him that all kinds of reconstruction dope would be necessary if he hoped to survive.

Uncle Sam didn't at first believe that he was so desperately sick. He had symptons, it is true, but then we all have symptoms, even when in the best of health. Straightway, as soon as he was told he was in a hard pass, Uncle Sam set himself down and tried to feel all the diseases the experts told him he ought to feel. He hadn't a spot without a pain, unless, indeed, it was a spot he hadn't pondered over. With such a sensitive bundle of nerves, with such a heated imagination, he could feel pain anywhere by taking due thought. The M.D.'s told him that he ought to feel sick all over, and he did. He has fairly worried himself into the "flu."

Let him bid goodby to his many doctors. The medicine they give may help a little, but it has to be continued and the dose increased if it is going to do any good. Subsidies, unusual Government developments and what not tone the part but wreck the stomach. The medicine soon ruins the whole man. What he need is cheerfulness and faith, and then we can leave in the shadow the old Uncle Sam who contemplates only whoas and woes, and go forward with the new Uncle Sam, buoyant and triumphant.

In this era of world reconstruction the great cry is for increased efficiency. This, of course, means the more general adoption of scientific management. The question is, How can we get this better efficiency and consequent higher individual production if the labor unions persist in their opposition to studies in time and motion in industrial plants? The stop-watch is necessary in the compilation of records to promote individual efficiency. If shorter hours and higher wages are to continue, and labor is going to earn more than formerly, it must be educated to know the necessity of increasing unit production.

Will Prices Go Up or Down?

THERE are a lot of injustices in the world as the result of the world war. Some exceedingly valuable artisans have seen their wages remain stationary when the wages of those in other industries were going up without stint. They read of the plethora enjoyed by other people and went home to every form of stinted fare and meager comfort. The bricklayer and the stonemason heard about the large wages of the riveters and calkers, yet had to be content or leave the industry. They and a number of others will be looking, now that the war is over, for a readjustment in accordance with living costs.

Such adjustments can only be upward, for so long as wages in general are high, cost of living must continue high. The labor unions will not permit the present wage scale anywhere to be lowered. This change in the rates of pay of the artisans who have not hitherto secured increases will make for higher prices. In fact now seems the best time for building. Construction is likely to be more, rather than less, expensive later. The present is the time for much construction work. It can never be done at lower prices

It is a common saying that wages are too high for business expansion. Many wage scales are indeed extremely high as we look backward, but it does not appear that even the highest are anything but normal as we look forward. And the future price of services, as of real estate and goods, is what really concerns us. Why lament that we cannot buy labor at 1913 prices when we have to manufacture or produce to sell during 1919?

The inflation of currency is widespread. If America alone had it we might expect it to fall like a wave in the ocean. But it is found everywhere, and is plainest in those countries where wages used to be lowest. Russia and Germany, which used to have low wages, now compensate labor more largely than ever, though of course the values of the coins in which wages are paid are far more inflated than our own. They are moreover uncertain. They all may be, and some will surely be, lowered when the period of revolution terminates.

But, nevertheless, no one can say that inflation is a purely local condition, peculiar to America. It is an international condition and in large degree it will endure. A little later the cost of living may descend, but the cost of construction is likely to rise. Even the cost

of living will depend on the harvest of the coming year, and conditions this winter may well not be favorable, for mild winters without much snow expose the winter wheat to all the rigors of the season.

All shelves are bare and many raw materials are short. It is said that in the Middle West the department and dry-goods stores were almost swept clean by the Christmas trade. The white-goods trade that followed swept the shelves completely, and buyers made trips to the East to try and replenish their stores, shipping the goods home by express. Everyone is now in need of goods. Most of us have been saving and have the money with which to buy. Banks are well supplied with the wherewithal for loans. What is lacking is confidence, not in credits so much as in the stability of prices. That confidence must soon be re-established, for prices of many things are lower than they are likely to be later. When the fact becomes duly impressed in the mind of the public there is going to be some spirited buying and a further inflation of values, especially in surficial forms of real estate.

The coal-mine manager today can do no more profitable and patriotic work among his employees than to campaign vigorously for a continuation of the thrift habit that secured such a good start in this country during the days of the war. Hoards of agents hawking all sorts of doubtful investments are busy tempting workmen to convert their Liberty Bonds and invest the proceeds in worthless securities. Every obstacle should be placed in the way of these cheaters and every incentive should be put forth to encourage the hard-working wage earners to avoid a return to the ways of extravagance and improvident spending. Nothing will do more to keep the wheels turning and promote a resumption of industrial activity than a continuation of nation-wide thrift. Accumulated wealth reproduces itself, and in doing so labor must be employed.

Because This Is a Government of the People

BECAUSE this is a Government of the people and by the people, it has the psychology of the people. It rises only with great difficulty above and beyond them. When times are good the nation buys, and it jostles to get what it needs. When times are bad it waits. When the public crowds to enter a door, or to circle round a mountebank, everyone else is drawn to do the selfsame thing. Similarly Uncle Sam, who is the American people in composite, will be found trying to go where everyone has gone. Because, by reason of our representative system, he is a cross-section of the public, he is almost sure to have the national psychology as his own.

Thus it is that we find the Government is skimping just now in its buying of railroad material, especially coal, and in its improvement of railroad lines. It is restricting its public building program. It will be found also that cities in the East are hesitating to build sewers, public buildings, disposal works or roads. The national mind, like the corporation mind, is the mind of the people. When the individual halts and fears, we all halt and fear. We all oppose expenditures. Uncle Sam sees John Smith has a wobbling step, and he sets his gait to suit.

However, given a public with hope in its breast, with a strut and with spirit, and Uncle Sam is a new man. He remarks that the day is bracing and spends a billion without much ado; and everyone of his grown children—the states in the Union—and all his smaller children—the municipalities or towns—do the same. So eager is he to get his work done that he rudely jostles the individual or corporation, seeking the same goal.

Too bad Uncle Sam has our psychology. If he had one of his own how he would trim the rocking boat of state! How he could create briskness and cheerfulness out of fear and despondency, and prevent surfeiting and congestion in times of overconfidence! He would serve us better, would our Uncle Sam, if only he were less like us.

Will War Bring a Foreign Psychology?

THE nations of Europe always had a psychology different from ours. No one, perhaps, knows why. Perhaps our energy is the cause. We must be ever up and doing, must make or break, must see things to an early conclusion. Whatever the reason has been, we were the people—the people of all the whole world—who discovered that sometimes it paid to conduct a business at a loss. And often indeed we so conducted it.

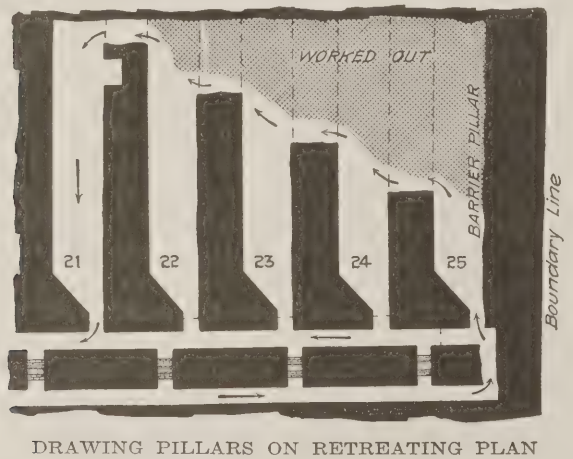
The arguments we had were good; that there is no use denying. We liked them the better because they were a trifle hard for the outsider to understand. But logical and solid in a way they certainly were. No! they will not be repeated here. Better that they should be entirely forgotten, for while they are true for the individual if he alone goes where they lead, they are not true, emphatically not true, for the industry as a whole or for the nation as a unit.

If an individual could induce all other individuals to sell at a profit, and he were to sell at a small loss, then it might be advantageous to him to do it rather than close down his operation. But if the other individuals show a disposition to cut their prices below producing cost, then it is up to the individual, who in a time of depression wants to keep running, with any degree of steadiness, to accept a little further loss. This is the "eternal spiral," if we may quote the expression of the British economists and twist its meaning to suit the present subject. They apply it to wage rises and costs of living. Here it is applied to the acceptance of a loss as a cause of progressively lower prices.

It is untrue, then, that it pays the individual to accept a loss, for he cannot prevent other individuals from doing the same and making other losses necessary. It is better to look at matters with more philosophy. It is better to say that selling for less than cost is a crime against the industry. Worse yet, it is a crime against the state; for if every individual in every industry did it, there would be a using up of capital; and the progress of mankind would be stopped, and civilization itself would be thrust even backward. Profitless operation is a using up of past accumulations. It is a destroying of fluid capital and an acquiescence in the decay of fixed capital.

So we need a psychology that will protect us against cutthroat competition, against our own self-destroying energies. Everyone but the American business man has it, and why not we?

DISCUSSION BY READERS



Drawing Pillars in Machine Mining

Letter No. 3—In looking over the inquiries in *Coal Age*, not long since, I ran across one from a brother foreman who asked for the experience of others who have used the Sullivan shortwall machine, in drawing pillars. Unfortunately, he has neglected to give the thickness of the pillar and some other data that would be of interest; but I am glad to give him my own experience along this line.

During the time that I was foreman of No. 1 mine of the Jefferson & Clearfield Coal and Iron Co., I was ordered to draw all the ribs in a part of the mine known as the "Ninth left." The coal in this section was 5 ft. high, overlaid with a slate roof, and pitched about 6 per cent. across the rooms, which were about 300 ft. long and varied from 20 to 35 ft. in width. These rooms were turned on 50-ft. centers.

Before going further, I want it understood that this work was driven before I took charge of the mine. The shape that it was in was a disgrace to any mine foreman. The mine was a machine mine entirely, no pick miners being employed, and I was obliged to undertake the task of drawing back the pillars with the machines.

After a short study of the situation and the conditions, I decided to adopt the plan shown in the accompanying figure. Starting at the last place on the heading, I determined to take out five pillars at a time, keeping the ends of the pillars a short distance, one in advance of the other next following, as I have shown in the sketch. This gave me a good line of break, more or less corresponding to the strike of the seam.

DRAWING PILLARS ON RETREATING PLAN

My method of attack, as shown on the left of the figure, where the pillar has been cut through at the face and a second cut started, was to cut through the rib, making a 15-ft. opening each time and leaving about 6 ft. of a stub between each cut and the last one. This 6-ft. stub, at the inby end, protected the cutter while at work. Sometimes this could be taken out by the machine, after the 15-ft. cut had been completed. At other times, it would be necessary to take the stump out with picks, which was done before the next cut was started.

One thing is important, and that is to see that all the posts are removed and none left standing in the gob. This is necessary, in order to keep a clean line of break extending across the ends of the pillars. I removed better than 90 per cent. of the coal from these pillars and rescued two-thirds of the timber. Considering the great variation in the thickness of the ribs, in this case, it was better than I had expected. I hope that my experience may be of benefit and help, not only to this brother foreman, but to others who have similar work on hand.

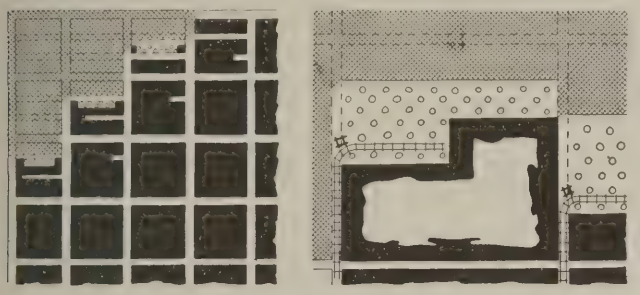
SAMUEL JONES.

Johnstown, Penn.

Letter No. 4—In reply to the inquiry regarding the drawing of pillars in machine mining, *Coal Age*, Jan. 2, p. 32, it would be easier to suggest the best method to apply in that case had the inquirer given the size of the pillars left between the rooms. He gives the width of the rooms as 27 ft. and the depth of cover 200 ft.; but says nothing of the width of pillars that are to be drawn, which is an important matter.

However, I want to give, frankly, a little of my own experience in drawing pillars by machines, in a mine of which I had charge as foreman. In one section of the mine, I determined to try drawing the pillars on the retreating system, keeping one pillar about three cuts in advance of the one ahead of it or outby, thus making the pillar work somewhat after the fashion of a longwall face.

FAILURE REQUIRES ADOPTION OF A NEW PLAN



The coal was overlaid with a strong sandstone roof. For a while, the plan succeeded well and gave good results, although I watched with some anxiety for the breaking of the hard sandstone roof, which had not yet taken place. Much to my dismay, when the roof broke, it broke right up to the face of each pillar, in each case cutting off the straight face of the pillar.

Evidently, another plan had to be adopted if we were to succeed in drawing these pillars, by machines, under this roof. In order to start the work again, I had to cut across each pillar and open up a new face. But, from that time on, there was trouble, as the posts that were stood behind the face were not strong enough to break off the hard rock forming the roof. After some study, I decided to adopt an entirely different plan that I was convinced would give better results and save pillar coal, much of which had been lost in the previous method.

As shown in the accompanying figure, the plan now adopted was a longwall panel system, retreating. Eventually, I tried two systems, both of which are shown in the figure. By the first system, as shown on the right, the face of the panel was taken out in lifts. This

method was fairly successful, but did not give as good results as the second method, which is shown on the left of the figure. The drawing of the posts in one lift was left, until the next lift was finished. By this means there were always three rows of posts behind the lift that was being worked. As shown in the figure, one or two cribs were built at the side of the lift where the track entered, so as to give greater protection at that point.

As just stated, the second method, shown on the left of the figure, was the better of the two. In this method,

SHOWING TWO SUCCESSFUL METHODS OF WORKING

each pillar was split into two or three parts, according to the size of the panel. The hatched portion of the figure shows the portion of the mine where the coal had been worked out, the dotted lines indicating how each panel was split. As shown in the figure, a stump was left at each end of the cut, in order to give better protection for the machine while it was at work. These stumps were afterward taken out with the pick.

The aim in splitting a pillar was to divide it so as to provide two cuts for the machine in each part. These cuts were made on the gob side; but when the two cuts were finished, if the place was in good shape, I would frequently continue and take a cut on the other side, which made a total of three cuts for one split of the pillar.

I consider that this second plan is the safest and most practical method for taking out pillars with machines when the coal is overlaid with a hard rock roof that is difficult to break. WM. DICKINSON, SR.

Oak Hill, W. Va.

Effect of Prohibition in Mining

Letter No. 1—Now that the required number of states have ratified the constitutional amendment passed by Congress a short time ago, and national prohibition will soon be a fact in this country, I recall again the remark made by J. H. Tipton, *Coal Age*, Dec. 12, p. 1087, to the effect that "too much emphasis" has been placed on the matter of intemperance among the miners.

This suggestion was made by Mr. Tipton in discussing the hindrances to coal production. While I agree with most of what he has said and do not want, for a moment, to disparage the numerous good points made regarding the effect of other hindrances to coal production, I must take issue with him on that one point.

Too much emphasis, in my opinion, cannot be laid on the evil effect of intemperance among miners. It has been the cause of the loss of thousands of tons of coal when that was most badly needed. It has been responsible for the personal injury of many mine workers, because a drinker has been permitted to enter the mine when unfit for work and in a condition in which he could not be held responsible for his acts, which endangered not only his own life but the lives, also, of his coworkers.

In his letter, Mr. Tipton offers some important suggestions for overcoming hindrances to the production of coal. He makes special mention of improving the living conditions of miners, and speaks of the need of greater efficiency on the part of foremen in charge of mines. I am convinced that if proper living conditions are provided and some form of amusement and recreation furnished the men, in mining towns and camps, there would be less drinking, and the chief hindrance to the production of coal would be removed.

If one takes the trouble to compare the loss of production due to intemperance in a mining community where these things are provided, with the loss from the same cause in a community where no such privileges are offered and nothing done to keep the miner out of the saloon, it will be found that the loss will be considerably greater in the latter instance than in the former.

Let me repeat what I said in the beginning, that too much emphasis has not been laid on the effect of intemperance to reduce the production of coal. As long as the manufacture and sale of liquor is a legal business and the doors of the saloon are open to miners and other industrial workers, the effect can only be to hinder production in all industries. But, to none will national prohibition prove a greater boon than to coal mining.

Pittsburgh, Penn. EDWARD H. COXE.

Living Condition at Mines

Letter No. 1—As the readers of *Coal Age* all know, labor conditions have been very unsettled, during the past two years at least, and there is not much improvement apparent at the present time. The principal trouble is experienced in isolated mining districts where the dwellers have not the same privileges that are afforded residents of larger towns and cities.

The thought that has been uppermost in the minds of many coal operators, not only in such isolated districts as I have mentioned, but elsewhere, is how hard it is to get labor and to hold it. The labor question, indeed, has caused much thoughtful discussion. Various remedies have been suggested, some of which have been tried out with good results, while others have proved failures.

Having spent all my life in and around coal mines and, for the last 15 years, serving as a mine official, I have been led to make a careful study of the miner, both at work and at play. Let me say then, here and now, that with few exceptions, the natural disposition of the miner is one of pride. He asks no one to give him anything but justice, being proud of his ability to earn his living and pay for all his necessities.

The argument has been advanced that to close the saloon and abolish booze will solve the labor question in mining; but that is only partially true. While it will make sober men out of drinkers, it will not hold mine workers in isolated districts that are devoid of those common privileges that make living worth while, such as schools, churches, good roads and dwellings, with

places of amusement and recreation. Observation while living in such districts makes this conviction, in my mind, a fact.

From time to time, when good men were quitting our mines for work in other places, my inquiries as to the cause of their leaving would almost always bring the following responses: "There are no good roads in this town."—"The schools here are no good."—"There are no churches here that we can attend."—"My family are unable to get what they need at the store," etc. Seldom did it happen that a man would leave because of a simple error in his accounts, which was always quickly corrected at the office and the man satisfied.

When I would take a man to task for getting drunk and laying off he would promptly reply that there was "no place but the saloon" where he could go and spend an hour or so when out of the mine; "no shows, poolrooms, bowling alleys, or even a reading room," where he could spend his spare time. Many would claim that they did not want to stay at home all the time and must go somewhere.

Taking these facts into consideration, let me ask if coal operators have ever wondered why they could get and keep labor with less difficulty where a mine is located close to a town, than where it is located in an isolated district; even though the working conditions in the former were inferior to those in the latter instance. Can anyone deny that it is the duty of mine officials to deal strictly, fairly and honestly with men in their service? Does anyone doubt that that is the only way to get and hold their confidence?

Efforts of Mine Officials Necessary to Promote Satisfaction Among Employees

It may and generally will require much extra effort, on the part of mine officials, to secure for their men these privileges, which are accounted as essential to good living conditions. The question of "good roads" is one to be taken up and advocated strongly by the operator who pays the taxes. Likewise, the matter of providing "good schools" is one that will depend on the influence and the interest that the mine management and officials take in matters relating to the school board.

As to the "church," very often a small donation of either money or ground, on the part of the operator, will encourage the residents of the camp to build a church and pay their share toward the maintenance of its services. Where this is not practicable, at the present time, there are generally two or more houses standing empty that could, with a few necessary changes, be made available for service, both Protestant and Catholic. Other places could be provided as "reading rooms, poolrooms, and bowling alleys."

A wise management will endeavor to provide the occupants of the company houses with such conveniences as they may desire or need for their comfort. Some dwellers may even desire electric lights. Most will desire baths and toilet conveniences. Speaking of baths, however, it must be admitted that there are some, among the foreigners, who will not take proper care of a bathroom should it be provided for them. These should not have such conveniences, until they are educated sufficiently in their proper use and care.

Finally, in regard to the "company store," there should be provided a good uptodate department store, where the miner and his family can procure what they need and desire, at prices at least as low as the same goods can be bought elsewhere. Customers should be treated with the utmost courtesy and fairness.

The education of the miner has elevated him to a standard of living where the conveniences and privileges I have mentioned have become necessities to him and his family. What the miner needs, aside from good working conditions, are home surroundings that he is qualified to appreciate and amply able to purchase, for the comfort of himself and family. All that I have mentioned can, under proper management, be made self-supporting and not a source of expense, but a source, rather, from which will come an increased production of coal.

A. A. Allen, Asst. Genl. Supt.,
Pittsburgh, Penn. United Coal Corporation.

Perils in Reconstruction

Letter No. 2—Now that the war is over and the mines will soon be running full-handed again, we begin to wonder what hindrances will arise in the future to restrict the production at the mines. No one is expecting to witness soon again the conditions that hampered the mining of coal and caused so much suffering a year ago. During all that trying period, miners proved their patriotism and showed that they were worthy of the trust reposed in them.

Now, however, the situation that confronts us is of a different nature than what existed during the time this country was at war. We are now facing a crisis that will demand the best judgment of operators and miners alike. The most difficult of the problems liable to arise is the adjustment of labor questions. Unfortunately, as we are all well aware, there is a dangerous propaganda that is being circulated daily among our miners. If this is not soon checked, it is bound to create conditions that the miners themselves do not desire. Strange as it may seem, the miners are unwittingly permitting themselves to fall victims to what we can describe by no better term than "Bolshevism."

Earnest Appeal to Labor to Make Good

No one doubts, today, that we are entering upon the most important period respecting the future of this and other countries. Regard for one another's welfare must now take the place of selfish ambition and it is for the people of America to prove to the world that the love of one's fellowmen is a more powerful factor in securing equity and justice than is violence and bloodshed, which must follow in the wake of Bolshevism. It is to be hoped that the laboring element of this country will prove all that is claimed for it by the President, who has stated that he considers it the most important asset of the nation.

One condition that it behooves all mine superintendents and foremen to consider carefully and prepare plans to meet is the homecoming of our boys, who responded so nobly to the call of their country in its hour of need. No doubt, the quick return of the boys will change industrial conditions throughout the country; but the effect in coal mining should prove a benefit by displacing some who are unacquainted with mining conditions and whose employment was forced by the urgent need of men to get out the coal.

When we consider that there was enough work for these men before they entered the war, and realize the large number of them who have been slain or crippled for life, and others who will not return because of affiliations formed abroad, it should be clear that there will be work and *steady work* for all.

In closing, let me urge that we give this matter serious consideration and prepare ourselves for the change that is coming and is even now here. Any intelligent foreman will welcome the advice and knowledge to be gained through a practical discussion of ways and means to meet the situation with fortitude.

Plymouth, Penn. JOSEPH R. THOMAS.

Letter No. 3—I have been impressed with the numerous predictions that have been made from time to time, in regard to what was going to happen after the war. While some have claimed that the end of the war will mark a period of unprecedented prosperity, others predict that it will bring a time of trade depression and uncertainty. Still others believe that we shall pass from war to peace as easily as sliding off a log.

Now, while I despise the attitude of a pessimist, the thought that impresses me most is that, looking at things as they are, big changes are in sight. But, before there will be any great change for the better, we shall experience a change for the worse. Everyone, therefore, should put his house in order and prepare himself to meet this change when it comes.

EFFECT OF RECONSTRUCTION WORK IN EUROPE ON LABOR IN THIS COUNTRY

The work of reconstruction in Europe, many believe, will call a large number of our foreign labor home. If this should take place it would undoubtedly imperil many of our industries, particularly the mining of coal. At the same time, it must be remembered that there will be thousands of those in foreign lands who will seek a home on American soil when the first opportunity offers, and this influx may more than offset the loss to us of those who return to their own country.

Also, the anticipated scarcity of labor in this country will be largely counterbalanced by the return to their homes of our 3,000,000 soldiers in training and in service. In addition to this, the shutting down of munitions factories and the slowing down of our shipbuilding will greatly augment the available labor force here. It is well known that thousands of our miners left the mines to work in these factories. Moreover, the slacking down of mills, closing of factories and the cessation of other war activities will greatly reduce the demand for coal. In fact, according to the market reports, there is an increasing amount of coal already on hand; and this, in face of the fact that production at the mines has been greatly impaired by the influenza epidemic, shows that the demand for coal is already falling off.

What will be the effect of our Government withdrawing its protective hand that has, for some time past, controlled both the price and the shipment of coal, it is hard to say. Competition will increase, in the coal industry, with the result that the price of coal will be lowered and this, in turn, will reduce wages, which means a struggle, unless the price of living necessities is likewise reduced. Should these things occur, we would face a new peril in the form of labor disturbances.

No doubt, it will be argued that the building of a great merchant fleet will soon enable the carrying of our coal all over the world and that this will act to stimulate the coal trade. It is asserted that we can produce coal as cheaply as England; but, our country being a self-supporting nation, making larger exports than imports, presents the difficulty that our ships carrying coal to foreign ports must return in water ballast, while English ships will take home a cargo of much needed supplies. It does not take a scholar to estimate the difference in the price of our coal and that of England, in foreign ports, under these conditions.

Let us look boldly at these perils and do what we can to overcome them before they are upon us. We are proud to have brought peace to the war-ravished countries of Europe; let us not fail, now, in securing a lasting industrial peace to ourselves and the world.

McIntyre, Penn. THOMAS HOGARTH.

Quality of Mine Timber

Letter No. 1—Reading the recent letters, regarding the drawing of pillars in machine mining, which have appeared in *Coal Age*, calls to my mind an incident that occurred, a short time since, when the division superintendent, the mine superintendent and myself, were making an inspection of the mine of which I had charge.

On that occasion, we had stopped, in a certain miner's place, for a few moments' rest. While seated there, the conversation turned on the drawing back of pillars, which work had just been started in that section, and the division superintendent remarked that I should be sure to see that the rooms were well posted before ever starting to rob the pillars.

The miner, who was working the place, had been attentive to all that was said and, at this juncture, butted in with the remark, "Yes, but we need better posts than those that were brought in to me today. You would hardly believe that I broke one of them in two, trying to drive it up in place. They are entirely too small and not strong enough to support this roof. They make me think that they were made more for match sticks than for mine posts."

THE TRUTH SPOKEN FRANKLY AND BOLDLY

The miner, whose life was daily in jeopardy by reason of the poor quality of timber sent to him, was more outspoken than most men working in the mine would have been. That he had spoken the truth, however, was plainly evident and it made its impression where the lesson was most needed. It is unnecessary to add that a better quality of posts was sent into the mine from that time forward, particularly where they were needed in pillar work.

I mention this little incident in the hope of drawing attention to the quality of timber often furnished to miners, both in respect to the size of the sticks and the kind of timber employed. Ash, oak and other hardwood timbers are better adapted for use on roads and aircourses where they must remain for some time, while pine, hemlock, spruce and many like soft timbers give better service in rooms where the yielding of the posts is an important factor in observing the movement of the

roof and the pressure on the timbers. However, the size of all post timber, hard or soft, must be such as to give the required strength. FOREMAN.

———, Penn.

Freezing of Shaft in Winter

Letter No. 10—After reading the several letters that have appeared in *Coal Age*, in regard to preventing the freezing of a shaft in winter, it seems to me that half of the writers have forgotten that there are many mines that are equipped electrically and have no steam to use for this purpose. The other half seem to ignore the fact that the one main point that is necessary to be considered is the rise of temperature required to prevent the freezing of the water draining into the shaft.

Now, it does not appear to me that it would pay, where a mine is electrically equipped, to install a boiler for the purpose of generating steam when the weather is sufficiently cold to freeze the shaft, which would be at irregular intervals during the winter. Those who advocate the use of steam argue that this would increase the humidity of the mine air; but it strikes me that, if the air is preheated before passing down the damp shaft, it will absorb the required amount of moisture and accomplish the same purpose.

It is suggested in Letter No. 1, which appeared in *Coal Age*, Dec. 19, p. 1134, that all that is needed to heat the air is a hot-air chamber installed near the top of the shaft. If the suggested 12-in. pipe is not sufficient for the purpose desired, there can be any number of pipes, or a much larger pipe, installed to conduct the hot air down into the shaft.

For that matter, a rectangular pipe 3 x 8 ft. in section, giving an area of 24 sq.ft., could be used. Also, if necessary, two such hot-air chambers could be installed for heating the air. This method appeals to me as being more practical and simple than those suggested.

Holsopple, Penn. MINER.

[This letter will close the discussion on "Freezing of Shafts in Winter."—EDITOR.]

Perplexities of Mine Foremen

Letter No. 10—Among the several letters that have been written describing various perplexities that are the lot of mine foremen, none have impressed me so forcibly as the letter of John Rose, which appeared in *Coal Age*, Nov. 28, p. 1002. As Mr. Rose says, there is a class of miners that are continually on the hunt for the boss to make some complaint.

My experience is that there are few mine foremen who will not listen to a man when he has a serious complaint to make. A good foreman very quickly learns to know who the miners are that are never satisfied but are continually kicking about one thing or another. Were the foreman to attend to every such complaint, he would have little time left to see that the mine is kept safe and the coal moving.

When a mine foreman has done his duty and furnished the necessary material to make a man's place safe and the miner has not done his part to keep up his place, it is no fault of the foreman's that trouble overtakes the man. A foreman cannot waste his time going to look at such a place, especially when he knows that the miner will load no more coal if his place was timbered for him.

On the other hand, a good man can usually get all the help he needs from his foreman, who has come to know the value of the man's service in maintaining the output of the mine. After all, it is the man who produces the most coal who has no difficulty in securing the prompt attention of his foreman when he has a complaint to offer.

It is true that during the recent labor shortage, many mine foremen have spoiled their men by doing more for them than customary. This has resulted in some miners starting to do as they please; and, in a short time, they please to do very little. From fear of losing their men, many foremen have adopted these methods to hold them.

False Claims of Incompetent Foremen

Foremen who are constantly making concessions are prone to boast of their ability to handle men, when, in fact, the man has often proved to be the real boss. I am glad to say it is not so in every case. There are foremen who will not keep a man on the payroll if he does not work to their satisfaction. While such treatment may sometimes work a hardship on the men who wish to do right, by starting unmerited rumors of harsh dealing, good results will be accomplished in the end.

As an illustration of how unreasonable some men are, let me cite an instance that occurred a short time ago. The track on one of the main hallways, in a mine, had just been torn up by the derailment of a loaded car. There were 25 men working on that section and, not to delay their work, I started at once to find the trackmen. They were busy fixing the track in a place where two men were waiting to load a car.

Explaining the situation in a few words, I sent the trackmen to repair the track on the main haul, telling them to then return and fix the track for the two men in the room. I stated that it would not require more than 45 min. to complete both jobs. In spite of everything that I could say or do, however, the two men took their buckets and went home for the day, although their track was fixed and ready for them before they could have gotten out of the mine.

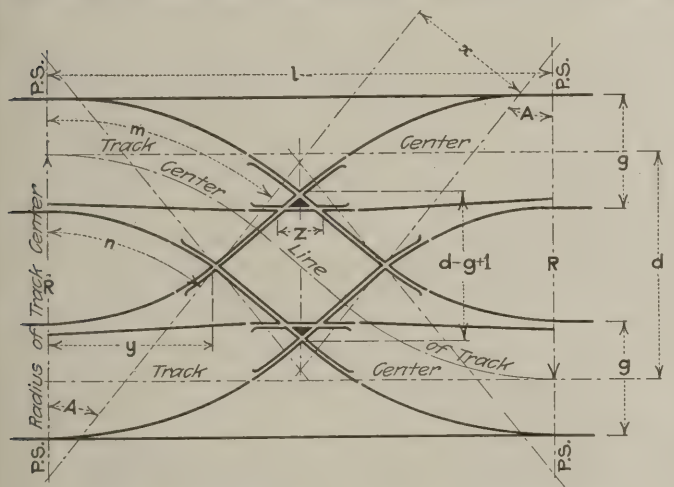
Unreasoning Acts of Men Annoy Good Foremen

It is such acts of unreasonableness on the part of men that perplex and worry mine foremen. The average foreman is full of "pep" and anxious to keep things moving while, at the same time, endeavoring to satisfy his men. He realizes that his chances are small of ever making good unless he can keep a satisfied bunch of men.

While not neglecting too long the little things that require his attention each day, a foreman must give himself chiefly to the larger and more important matters that affect the safe and efficient operation of the mine. The discussion of these conditions that are so well known to mining men has done much, within the past two years, to enlighten the general public and secure a fairer judgment on their part, regarding the men in charge of coal-mining operations.

Cleaton, Ky. OSTEL BULLOCK.

[The discussion of "Perplexities of Mine Foremen" will close with Letter No. 12 now on hand.—EDITOR.]



INQUIRIES OF GENERAL INTEREST

Diamond Crossover in a Mine

As mine foreman, I would like to be able to understand the method of calculating the different dimensions of a diamond crossover, such as is commonly used at a shaft bottom, for cross-caging, to enable the loaded cars to be run on either cage and permit of the removal of the empties. I shall much appreciate the favor if you can give me the formulas required to work out these several dimensions. FRANZ WALTHERS.

Buckskin, Ind.

When a diamond crossover is to be laid, the data commonly given or known are the gage of the track and the distance between track centers. Four frogs are required, two of which lie midway between the two tracks. The other two frogs are cast so that a small triangle of solid iron forms the center of each frog. The three sides of the triangle are parallel to the respective gage lines of the three rails crossing each other on this frog. To insure successful operation, these three gage lines must cross each other at three separate points, corresponding to the three apices of the triangle. The accompanying figure shows the general arrangement of the two main tracks, the crossover rails and the four frogs.

THE DIMENSIONS OF A DIAMOND CROSSOVER

It is important to remember that the arrangement of the tracks in a diamond crossover is symmetrical with respect to its central axes. The gage lines of the switch rails crossing the frog in the main track, each make an angle with the gage line of the main rail equal to the angle subtended by the curved switch rails, or the angle A, indicated in the figure.

The first step is to find the angle A that subtends each of the curved rails of the switch. To simplify the calculation, we will assume that the two gage lines of the switch rails cross each other 6 in. inside of the gage line of the main rail. Then, calling the distance between track centers d and the track gage g, the distance measured straight across the main tracks, between the two points where the gage lines of the two switch rails across each other, is $d - g + 1$, as indicated in the figure. The required angle subtending each curved switch rail is then found by substituting the given values in the formula

$$Cos\ A = \frac{g}{d - g + 1} \qquad (1)$$

The next step is to find the length l, out to out, of the diamond. This is the distance from point of switch (P. S.) to point of switch, measured on the straight track, as indicated in the figure. A convenient length of radius R, which is the radius of the center line of each switch, is first assumed. The chosen length of this radius must be such as to conform to the given track dimensions and the approximate desired length (l) of the diamond.

For instance, the shorter the radius chosen, the sharper will be the curvature of the switch rails and the shorter the diamond. On the other hand, where the room permits a longer radius can be chosen, giving easier curves but lengthening the diamond. Having chosen the radius R, the length l of the diamond is found by the formula,

$$l = 2R\,sin\,A + \frac{d - 2R(1 - cos\,A)}{tan\,A} \qquad (2)$$

The length (x) of the straight piece of rail, joining the opposite switch rails of the crossover, is next found by substituting the given values in the formula

$$x = \frac{l - 2R\,sin\,A}{cos\,A} \qquad (3)$$

It is evident that the radius of the outer curved switch rail is $R + \frac{1}{2}g$; and that of the inner curved switch rail, $R - \frac{1}{2}g$. Then, the length (m) of the outer curved rail, in each switch, is found by the formula

$$m = \frac{A}{180^\circ} \times 3.1416(R + \tfrac{1}{2}g) \qquad (4)$$

Likewise, the length (n) of the inner curved rail is given by the formula

$$n = \frac{A}{180^\circ} \times 3.1416(R - \tfrac{1}{2}g) \qquad (5)$$

In formulas 4 and 5, the value of the angle A must be expressed in degrees and decimal of a degree.

Finally, the distance y, indicated in the figure, or the distance that each center frog is in advance of each main switch point, is found by the formula

$$y = \sqrt{(R - \tfrac{1}{2}g)(d - g) - \tfrac{1}{4}(d - g)^2} \qquad (6)$$

When laying out the triangular frog, assuming that the gage lines of the two switch rails across each other 6 in. inside of the gage line of the straight rail of the main track, the distance (z) between the two frog points (see figure), measured on the main rail, is $z = 1/\tan A$, which gives this distance expressed in feet; or $12/\tan A$, expressed in inches. The center line of the two triangular frogs corresponds to the center of the diamond crossing the tracks at right angles.

EXAMINATION QUESTIONS

British Columbia Examination Second Class, Dec. 17, 1918

(Selected Questions)

Ques.—What would be the danger arising from a blownout shot in a mine atmosphere charged with coal dust and a small percentage of firedamp?

Ans.—The occurrence of a blownout shot and the projection of a considerable volume of flame into a mine atmosphere charged with coal dust, especially when a small percentage of marsh gas is present, would result in the flame of the shot igniting the mixture and an explosion would follow. If methane or marsh gas is present in sufficient quantity to form firedamp the mixture would be fired by the flame of the shot even though no coal dust were present.

Whether the local explosion started by a blownout shot will be transmitted throughout the mine will depend upon the condition of the mine air and the passageways. If these contain accumulations of gas or dust, the explosion may be propagated throughout the mine. The contracted roads and airways in thin seams, by preventing the rapid expansion of the gases produced by an explosion, tend to increase the violence of the blast and extend the explosion. Thicker seams and larger areas provide for a greater expansion of the burning gases, which lowers the temperature and tends to arrest the explosion.

Ques.—In spontaneous combustion in a coal mine, what gases are produced? What are the probable causes of spontaneous combustion and what general precautions would you adopt to prevent it?

Ans.—The gases produced by any combustion in a coal mine will depend on the supply of air. Where this is sufficient for complete combustion to take place, carbon dioxide (CO_2) is formed; but if the supply of air is limited so that the combustion is more or less incomplete, some carbon monoxide (CO) will be produced, the quantity depending solely on the limitation of the air supply. In a close place, the oxygen of the air being partly consumed causes an excess of nitrogen as the result of the combustion.

The primary cause of spontaneous combustion is the generation of heat accompanied with the production of some carbon monoxide in a mass of carbonaceous material, owing to the slow oxidation of the carbon. The action is greatly accelerated where carbonaceous or oily and bituminous matters are stored in a place where there is no ventilation and the escape of the heat is prevented. To avoid the conditions producing spontaneous combustion, no accumulations of oily waste, fine coal dust or other carbonaceous material should be permitted in the mine. In the storing of large quantities of coal, suitable provision should be made for ventilating the pile, so as to carry off the heat and gas generated in the mass.

Ques.—How many cubic feet of marsh gas will be required to be generated in a mine, per minute, to render dangerous a current of 60,000 cu.ft. of air per minute?

Ans.—The answer to this question will depend on first determining what is the danger line in the particular mine in question. In the mining of anthracite coal, the danger line may be assumed to be reached when 3 per cent. of gas is present in the return airway; but steps should be taken to avoid possible danger before this condition is obtained. In the mining of bituminous coal, much will depend on the inflammability and character of the coal in respect to the formation of fine dust. Where the coal is highly inflammable and the mine dusty the danger point is reached when the gas in the return airway much exceeds one per cent.

Therefore, replying to the question in regard to the quantity of marsh gas required, in this case and on the assumed basis, in a bituminous mine, it may be stated that the danger point will be reached when the gas generated is $60{,}000 \times 0.01 = 600$ cu.ft. per minute.

Ques.—The total rubbing surface of a square airway is 150,000 sq.ft.; the length of the airway is 4500 ft. and the quantity of air passing 75,000 cu.ft. per min. What is the velocity of the air current, in feet per minute?

Ans.—The perimeter of this airway is $150{,}000 \div 4500 = 33\frac{1}{3}$ ft. The airway being square, the length of one side is $33\frac{1}{3} \div 4 = 8\frac{1}{3}$. The sectional area of the airway is $(8\frac{1}{3})^2 = 625/9$ sq.ft., and the velocity of the air current $75{,}000 \div 625/9 = 1080$ ft. per minute.

Ques.—The quantity of air passing in an airway is 140,000 cu.ft. per min., and the water gage is 2 in. What is the horsepower producing the ventilation?

Ans.—The pressure corresponding to a 2-in. water gage is $2 \times 5.2 = 10.4$ lb. per sq.ft. The horsepower producing this circulation is, therefore, $(140{,}000 \times 10.4) \div 33{,}000 = 44+$ horsepower.

Ques.—In an airway measuring 7 ft. 6 in. high, 8 ft. wide at the top and 9 ft. 6 in. at the bottom, the anemometer reads 350 r.p.m.; what is the quantity of air passing?

Ans.—The average width of this airway is $\frac{1}{2}(8 + 9\frac{1}{2}) = 8\frac{3}{4}$ ft. and the sectional area $7\frac{1}{2} \times 8\frac{3}{4} = 65\frac{5}{8}$ sq.ft. The quantity of air passing is, then, $65\frac{5}{8} \times 350 = 22{,}968+$ cu.ft. per minute.

Ques.—Describe the various means used for conducting and regulating the air current in mines.

Ans.—The most common means employed for conducting the air forward in mines is a brattice constructed of boards or canvas nailed to a row of posts set for that purpose. The air bridge, either an overcast or undercast, is used to conduct an air current across a roadway or another air-course and thereby avoid the use of doors on the entries. A regulator is a partition built in an airway and having a small hole to enable a portion of the air only to pass.

FOREIGN MARKETS AND EXPORT NEWS

War Board Justifies British Import Restriction

Great Britain's action in applying import restrictions, which cover a wide range of commodities, is fully justified in the opinion of the War Trade Board. In order that the reason which prompted the British to take that action may be better understood, the War Trade Board comments on it officially as follows:

For over four years Great Britain has been subject to the shock and strain of a war which not only required the sacrifice of life and intense human energy, but also necessitated the most stringent economic readjustment and the sacrifice of private business.

It is not strange, therefore, that Great Britain should today wish to make every legitimate effort to keep her commercial and economic status from falling into chaos, and instead to restore it to a state of equilibrium. In fact, to do anything else would be strange.

As a natural result of such a normal, patriotic aspiration, in order to bring her own manufactures to a state of stability approaching that of pre-war days, Great Britain finds it necessary to impose such import restrictions for the time being as will permit her the opportunity to reëstablish domestic business conditions on a normal basis. The import restrictions being imposed by Great Britain are for such purposes and are not to be regarded as of a permanent nature. In making for the return of normal domestic conditions in Great Britain, inducing the social welfare of the empire, such measures will tend toward economic and social stability throughout the associated governments and this country. And such a tendency is today recognized as vitally necessary for the formation of a lasting and fundamentally sound peace.

Simplified Bunker Procedure

The War Trade Board announces that it has adopted a new and much simplified form for use in connection with the issuance of bunker licenses. The new form is a Combined Application and License (No. B-1c), and supersedes Bunker Forms B-1a and B-1b.

When Bunker Form B-1 has been completely filled out and signed by the applicant and approved and countersigned by the agent of the Bureau of Transportation or Collector of Customs, as the case may be, it will constitute a bunker license for all bunker fuel and ship's stores aboard the vessel and those desired to be taken on at the port where the application is submitted, as well as at any subsequent port in the United States or its possessions at which the vessel calls on the voyage for which license is issued, it no longer being necessary to obtain supplementary license at subsequent American ports when additional fuel or stores are desired.

A complete list of bunker forms at present in use follows: Bunker Form B-1c, Bunker Form B-3, Bunker Form B-4, Bunker Form B-5a or B-5b, Bunker Form B-7. Bunker Forms B-1c, B-3 and B-7 are required on all vessels. Bunker Forms B-4, B-5a and B-5b are not required of certain classes of vessels.

For further information, those interested should confer with Agents of the Bureau of Transportation, War Trade Board, or Collectors of Customs at ports where there are no agents.

Coal Exports From the Port of New York During 1918

Complete reports show that during 1918 there were shipped to foreign countries through the Port of New York 82,447 tons of anthracite, valued at $584,087; 48,717 tons of bituminous, valued at $349,369; and 10,937 tons of coke, valued at $174,114. In 1917 the exports from this port amounted to 134,252 tons of anthracite, valued at $987,178; 14,348 tons of bituminous, valued at $91,534; and 21,908 tons of coke, valued at $283,735.

Of the coal exported Canada received 68,763 tons of anthracite, valued at $482,834, an average cost of $7.02 per ton; 5487 tons were shipped to Newfoundland; 4669 tons to Cuba, and 220 tons to England.

France received 7140 tons of coke; Brazil, 1269 tons; Argentine, 2670 tons; and Italy, 220 tons.

The bituminous shipments were sent to many countries. Of the 48,717 tons exported Cuba received 1776 tons; San Domingo, 3988 tons; Canada 192 tons; Brazil, 27,065 tons; Argentine, 3750 tons, Dutch West Indian Islands, 2408 tons; Uruguay, 1750 tons; and the Falkland Islands, 3565 tons.

In 1917 Brazil received 1999 tons of bituminous through this port, and San Domingo, 755 tons. During the same period 98,402 tons of anthracite were shipped to Canada and 9445 tons to Newfoundland.

The shipments by months in 1918, as compared with 1917, are given in the accompanying table.

	Anthracite		Bituminous		Coke	
	1917	1918	1917	1918	1917	1918
January	7,934	490	2,049	530	1,660	1,599
February	4,981	1,184	1,731	2,157	1,211	44

December	6,831	4,614	959	1,213	1,716	2,694
Totals	134,252	82,447	14,348	48,717	21,908	10,937
Valuation	$987,178	$584,087	$91,534	$349,369	$283,735	$174,114
Average cost per ton	$7.34+	$7.08+	$6.37+	$7.17+	$12.95+	$15.92+

Foreign Freight Rates

W. W. Battie & Co.'s coal trade freight report for Feb. 3 states:

In the West Indian business few charters are effected owing to the scarcity of orders. Steamers may be had of most any size and position for this business. Owing to the scarcity of tonnage, the South American market is very dull. The chartering committee's rates are as follows:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge.

Sail (maximum) — Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net; Santos, $19.50 net; Buenos Aires, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. (Gross rates $1.50 per ton in excess of net rates). On all the foregoing rates, charterers pay vessel's towage to coal port. To Nitrate Range, $16.50 gross prepaid. (Same rate steam.)

The Chartering Committee's rate by steam is $19.50 net to Rio or Santos, $18.50 net to Buenos Aires and $19.50 net to Montevideo.

Ships Being Released

Vessels are being steadily released from Government service by the United States Shipping Board and placed back in trade service again. Coupled with the recent cuts in ocean freight rates, this is expected in some quarters to revive the export business. Some confustion is still being reported in connection with chartering and freights. Criticism has been heard of the cut in rates to some French ports when there is no American tonnage available to those ports.

COAL AND COKE NEWS

Harrisburg, Penn.

Sweeping amendments to the Compensation law, are planned by the State Federation of Labor, representatives of which body were in conference on Feb. 5, with Representative David Fowler, and floor leader, for the United Mine Workers. The amendments will be contained in one bill which was scheduled to be introduced in the house during the week of Feb. 10 by Mr. Fowler.

Chief among the amendments will be the increase of compensation to two-thirds of the wages. Under the present law, 50 per cent. is paid. At present compensation commences on the 15th day the person is away from work on account of injury, and from that time on an allowance of 50 per cent. of the person's wages is allowed as compensation. It is proposed to reduce this time to seven days.

It is also proposed that a stipulated number of weeks be allowed for the loss of fingers, toes or ears. At present compensation is allowed for only the time required for the specific injury to heal. According to the labor men, a stipulated number of weeks is allowed for loss of fingers, toes and ears in the provisions of the compensation law now in effect in New York State.

Following a conference at the capitol on Feb. 4, between Governor Sproul and a delegation of business men from the anthracite region, announcement was made that a bill, regulating the anthracite coal-mining industry in the state and aimed particularly at the conditions that exist in Scranton and Lackawanna County, will be introduced in the Senate by Senator Albert Davis. The bill carries with it a maximum penalty of $5000 in fines and one year imprisonment. The bill is wide in scope, taking in any possible damage that can be done by surface subsidence caused by mining operations. Some years back, Mr. Davis, then a representative in the House, fathered the "Davis Mine Cave Bill," providing for the protection to streets and thoroughfares.

Charleston, W. Va.

Production in the Pocahontas and Tug River districts advanced from 365,000 to 390,772 tons during the week ending Feb. 1. This was due in part to a slight improvement in the demand for Pocahontas coal. Labor shortage is still running rather high, having caused a loss of 22,360 tons, other sources of loss in production being negligible. The fact that tonnage produced in the two districts has almost reached 400,000 tons indicates a decided improvement in the Pocahontas region and some revival of the demand for smokeless coal.

A generally dull market has been reflected in the large number of mines which are either shut down or are being operated very irregularly in the Fairmont region. On Saturday, Feb. 1, the number of idle mines amounted to 174 as against about 150 for the previous week. While mines were idle, there was no diminution in the car supply, the daily supply running well over 3000 a day. The amount of coal loaded, however, was far below that, loads running not over five or six hundred a day, with few loads going to the West. Orders here and there, however, were regarded as being an encouraging sign and as reflecting a somewhat improved demand. Railroads, however, are still holding off on fuel orders, and this of course has restricted production somewhat.

In the Kanawha district there has been little change in conditions. If anything, it was duller as far as marketing coal was concerned, during the week ending Feb. 1, than it had been even in previous weeks. While smokeless coal in other districts showed sporadic spurts, there was nothing to stimulate production in the Kanawha district, the market being extremely dull. Prices, on the other hand were holding up well. In the absence of any special demand for coal, the car supply was plentiful. Owing to the flat market, a large part of the mines were not operating or else were being operated during only a part of the week. The total net tons produced was 84,452.

In the New River field there was little change in conditions during the week ending Feb. 1, extreme dullness characterizing the demand for New River coal. However, there was an advance in price despite the fact that the market was so lifeless. New River producers are confident that there will be a resumption in the demand for smokeless coal before other kinds of coal show any improvement. The largest losses in production during the period already mentioned were due to no market.

New York, N. Y.

The Wholesale Coal Trade Association of New York, Inc., has taken up with Walker D. Hines, Director General of Railroads, the matter of demurrage charges on coal at tidewater and in a letter to Mr. Hines states that the present demurrage regulations provide for three days' free time at tidewater, averaged month by month, and $3 per day per car thereafter. The movement of coal over the railroads, the Association says, is so uncertain as to time that it is impossible to calculate with any degree of certainty whatever, when the whole or any part of a shipment will reach the port of transshipment.

Demurrage charges, the Association says, are intended to prevent abuse of equipment, and where the carrier has performed in reasonable manner its obligation of transportation, are undoubtedly proper and beneficial to the shipping public; but in the circumstances under which coal is moved to tidewater their principal effect is to place an additional burden upon the commodity which must be borne by the consumer.

The imposing of these demurrage charges is a discrimination against all users of coal who have to depend on getting their supply by the water routes from the railroad terminals. In addition to raising the price at all times, they will find it difficult to get a sufficient supply, except in time of depression, for the reason that the risk of loss to shippers is so great that they will not send coal to tidewater if they can sell it elsewhere.

The Association believes that transportation charges and penalties should take into consideration the conditions surrounding the handling of a commodity, and those conditions at tidewater for the transshipment of coal are such that unless there is relief in respect of demurrage charges at the ports the result will be to defeat the very purpose of those charges—that is, the quick release and return to the mines of coal carrying equipment—and force the sending of shipments all-rail, tending to longer employment of equipment and further congestion on all railroad lines.

PENNSYLVANIA
Anthracite

Pottsville—Seventeen of the "individual" mines, all shippers via the Reading Ry., are idle in the Schuylkill region. The reason assigned is that they are up against it because of a glut in the market and no place to store the product. All the Reading Coal and Iron Co.'s collieries are in operation with one or two exceptions. Great quantities of coal are being stored at Landingville and Abrahams.

Wilkes-Barre—A complaint against the alleged practice of the anthracite coal companies throughout the region in importing cheap labor from New York City and other Eastern cities will be introduced at the Conciliation Board, it was decided at a meeting of the tri-district board, United Mine Workers, held on Feb. 5. It was learned that the matter will be considered as a general grievance, and if not settled drastic action will be resorted to.

Lansford—Although many mines in the Schuylkill and Wyoming regions have either shut down or are working on reduced time, all the collieries of the Panther Creek Valley operated by the Lehigh Coal and Navigation Co. are still operating to capacity; and there are no indications that they will shut down or work on reduced time. A large proportion of the coal mined by the Navigation company is sent to New England markets via the Lehigh & New England R.R., which is controlled by the Navigation.

Hazleton—Coal operators of the Lehigh field who were interviewed on the curtailment of work schedules at the mines because of the slump in the market due to mild weather and the shutting down of munitions plants, were confident that the conditions would not last long and that the collieries will be back on full shift within four months. They discourage the suggestion that instead of cutting the time from eight to seven hours the mines suspend Saturadys and Mondays, as they fear the three-day holiday each week would give Bolshevik agitators a chance to create trouble among the idle men.

Scranton—Throwing more than 2000 experienced mining men and laborers out of employment, the Delaware, Lackawanna and Western R.R., Coal Department, on Feb. 4, officially closed its three largest collieries operating in this section. Two of the collieries, the Continental and Brisbin, will be abandoned and both breakers dismantled. The Bellevue colliery will close for an indefinite period, throwing 850 men into temporary idleness. The closing of both the Continental and Brisbin collieries will mark another interesting page in anthracite history. The two collieries were among the first operated in the Lackawanna Valley.

West Scranton—Following a dispute relative to the method carried out in the loading of cars, the People's Coal Co. has refused to further handle the output of the See-Rob Coal Co., and as a result the mine of the latter company is closed. Officials explain that the arrangement between the two companies provides that the People's company take charge of the See-Rob company when it reaches the foot of the plane leading into the Five-foot vein of the former company. Certain phases of the contract have been broken, according to officers of the People's Coal Co.

Bituminous

Charleroi—The washeries of the Donald Nos. 2 and 4 mines of the Consolidated Coke Co., Grays Landing, Penn., are being rebuilt and equipped with the most modern machinery. H. R. Blackford, general superintendent, is in charge of the work.

Greensburg—Helen M. Bygate, of Pittsburgh, and J. Fred Kurtz, of Connellsville, have sold a tract of 167 acres of Pittsburgh seam coal to the Whyel Coke Co., of Uniontown. This undeveloped coal land is in North Huntingdon township, near Irwin. The consideration was $175,000.

Uniontown—Edward O'Brien has resigned as a member of the Mine Foremans' Examining Board of the 23d bituminous district, and on recommendation of Mine Inspector Richard Maize, chairman of the board, the Court appointed Joseph Forbes, of Grays Landing.

Waynesburg—Deeds have been recorded of sales in this county to the Cumberland Coal Co. They include 101 acres from Daniel M. Anderson for a consideration of $56,482.91 and the coal under a small lot in Jefferson borough from Malinda Alexander for $143.35.

Meyersdale—The bottom apparently has dropped out of the coal business in the Meyersdale region. Mine No. 4 of the Keystone Coal Co., was closed down recently, and many of the smaller mines such as Stotler, Schell, Meager and others along the Salisbury branch have been idle for several weeks, with no immediate prospects of resumption. The Atlantic Big Vein Coal Co., which operates the old Keystone opening, it is reported, has ordered its miners to remove their tools. It is said that there are at present more than 500 miners idle in the lower end of the Meyersdale region. The mines of the Consolidation Coal Co. in this section are operated only about half time. Many men are leaving the region and going elsewhere in search of employment.

WEST VIRGINIA

Eldorado—With the completion of its plant at this place, on the Coal and Coke Ry., the Foy Coal Co. is going ahead with mining operations, but is storing the coal so mined.

Clay—Having completed the construction of a siding to its lease of 1200 acres in Clay County, the Lima Coal Co. of Lima, Ohio, proposes to proceed with the construction of its plant with a view to the development of the coal under lease.

ALABAMA

Bessemer—The Gulf States Steel Co. is installing electric meters on the long hauls in its Virginia Mines, near here. Electrical machinery has also been placed to generate the power for the haulage and other units which will be operated by electricity in future. A new slope is also being put down to shorten the distance to the workings, which will enable an increased production to be obtained from the mines.

KENTUCKY

Mayking—The Pine Creek Lumber and Coal Co. plans development of timber and coal properties near Mayking, one of the new coal districts of the state. T. L. Tackett, of Enterprise, Ky., and E. R. Hay, of Winchester, Ky., are the principals in this concern.

High Splint—W. R. Grant, of Pittsburgh, Ky., has leased 500 acres of coal land from the Cooper Ridge Coal Co., of Evarts, Ky., and plans development. The Cooper Ridge Coal Co. recently increased its capital to $75,000, for the purpose of developing properties at High Splint.

OHIO

Lisbon—Extensive development of coal lands in Columbiana County is planned by the Glenwood Coal Co., recently formed by M. L. Gailey and John T. Harrington, both of Youngstown. The deposits are located four miles from Lisbon.

INDIANA

Hammond—A new coal bunker, 200 ft. wide, 1000 ft. long and 25 ft. deep, is being installed at the Whiting refinery of the Standard Oil Co. It will have a capacity of more than 125,000 tons of coal.

Bicknell—Mine No. 1 of the American Coal Mining Co. at this place, hoisted 6123 tons of coal in eight hours, filling 128 railroad cars. The American mine, which is owned largely in Terre Haute, Ind., and Brazil, Ind., some time ago set a record for hoisting 5911 tons of coal in eight hours. A few weeks ago an Illinois mine loaded 6008 tons in eight hours. The achievement of the Bicknell mine places it 120 tons in excess of the Illinois mine.

Belleville—Damage to the extent of between $3000 and $4000 was done to the engine room and the gas engines of the Southern Coal and Mining Co. in the Little Oak mine Feb. 6, as the result of an explosion of gasoline. The fire was confined wholly to the engine room and was soon extinguished, but not until two expensive gasoline engines had been badly damaged. The lives of twelve men were jeopardized by the explosion and seven men had considerable difficulty in escaping. About 300 employees were idle for two or three days until the damage was repaired.

ILLINOIS

Danville—The Brady Branch mine, near Tilton, is contemplating several improvements, as it is expected the Wabash R.R. will build a switch to the dump mines and extend an incline from the ravine to the top of the hill. About sixty men are employed at the Carbon Hill strip mine, north of Tilton, and work has been exceptionally good until within the past few weeks. At the Brady Branch mine 150 men are employed.

Divernon—Divernon miners of the Madison Coal Corporation mine are reported to have broken the Sangamon County coal-hoisting record, with 1051 cars in six hours and eight minutes.

Litchfield—In consequence of much hardship because of the closing of the two mines in Witt, near this city, the residents of the village have presented a petition to Congressman Wheeler asking that he take up the matter with the proper authorities with a view to having the mines reopened. The closing of the mines in Witt in 1916 and the subsequent closing of all of the grocery stores in the village except one, caused the residents to appeal to the state charities for assistance. The people of the village are attempting to prevent a repetition of the conditions prevailing two years ago.

Springfield—All coal mines of central Illinois not under contract are now running only two days a week because of the warm weather and decreased fuel consumption.

Benton—The Pond Creek Coal Co., popularly known as the "Bobby Dick Mine," has been sold to a Chicago firm of coal operators, who will operate it under the name of the Freeman Coal Mining Co. This is one of the best small mines in the Benton territory and has been a prosperous property. The mine is located in Franklin County, and according to the last fiscal year mined for the year nearly 300,000 tons of coal.

ARKANSAS

Hartford—The Central Coal and Coke Co. has taken over the old Prairie Creek No. 34 mine at Hartford and is developing an up-to-date operation. Complete new equipment has been installed, as the mine was practically destroyed during labor troubles some time ago. The estimated capacity of the mine is to be 2000 tons per day. Construction and rehabilitation work is under the supervision of John A. McCurry, who will also be superintendent of the operation.

OKLAHOMA

Lehigh—The Oklahoma Mining and Stripping Co. will finish its mine at this place within a short time. A 6-yd. Bucyrus shovel is being used for stripping the overburden and two 3-yd. draglines for loading coal. The company is also developing a slope mine near Lehigh, and later on expects to start work on another.

Foreign News

Sydney Mines, N. S.—The Nova Scotia Steel and Coal Co. plant was closed down temporarily on Feb. 3. Four batteries of coke ovens will be kept in operation and the remainder allowed to cool off. During the suspension of operations the open-hearth and blast furnaces, stoves and coke ovens will be dismantled and undergo extensive repairs.

Personals

William Reid has resigned as mine foreman for the Dor-Mar Coal Co. at Savan, Penn.

H. C. Drum, formerly inspector, has been made assistant general manager of the Consolidated Coke Co., Grays Landing, Penn.

W. L. Fisher, formerly with the Consolidation Coal Co., at Jenkins, Ky., is now chief engineer of the Consolidated Coke Co., Grays Landing, Penn.

Frank Christopher, of Steyer, Md., has been appointed superintendent of the mines of the Diamond Coal Co. on Scott's Run, Monongalia County, succeeding C. W. McDowell.

W. Kinter has resigned as superintendent of the Locust Colliery Co., operating mines at Locust, Penn. He is succeeded by **J. Woods**, formerly mine foreman for the Pittsburgh Gas Coal Co., at its Whiskey Run mines at West Lebanon, Penn.

Lester E. Armstrong has accepted a position as advisory engineer with the Powdered Coal Engineering and Equipment Co., of Chicago. Prior to his service in the air branch of the army, Mr. Armstrong was associated with Babcock & Wilcox.

C. F. Ice, having completed his duties as chief of the division of inspection of the office of the district representative of the U. S. Fuel Administration for the Fairmont region, has again taken up his duties as the general inspector of the Consolidation Coal Co.

John F. Nealis, who recently received his discharge from the aero observation branch of the service, is now associated with the Powdered Coal Engineering and Equipment Co., of Chicago, as advisory engineer. Mr. Nealis formerly had charge of research work for the U. S. Steel Corporation.

J. M. McHugh, of Birmingham, Ala., who has been superintendent of the Edgewater Mine of the Tennessee Coal, Iron and Railroad Co. for a number of years, has been appointed general superintendent of coal mines for the same company, having jurisdiction over all operations in the Birmingham district. Mr. McHugh succeeds John F. Meagher, who died Jan. 16.

Lucius W. Robinson, for many years president of the Rochester and Pittsburgh Coal and Iron Co. and its subsidiary companies, has retired from the active business and operating end. **B. M. Clark**, former vice president in charge of operations, has been made president to succeed Mr. Robinson. **F. M. Fritchman**, general manager of the companies, has been given Mr. Clark's post as vice president. No successor to Mr. Fritchman as general manager has yet been named.

Industrial News

New York, N. Y.—The K-B Pulverizer Co., manufacturer of the crusher familiarly known as the "K-B," recently removed from its former address, 86 Worth St., to 70-72 Worth St., New York City.

Charleston, W. Va.—A bill has been introduced in the West Virginia legislature providing for an increase of $2000 per year in the salary of the chief of the mine department, making a total salary of $5000. The bill also carries increases of $900 per year to each of the deputy inspectors.

Birmingham, Ala.—At the recent session of the Board of Examiners held in the office of Chief Mine Inspector C. H. Nesbitt, there was a total of 68 applicants for certificates of competency as firebosses and mine foremen, 46 of whom passed the tests successfully, certificates being issued to nine who qualified as fireboss, five as second-class mine foremen, and 32 as first-class mine foremen.

Fairmont, W. Va.—A meeting of creditors—the first one—of the Initial Coal Co., which was declared bankrupt a short time ago, was held on Saturday, Feb. 1, to elect a trustee. Clarence D. Robinson, of Fairmont, a well known coal operator, has already been appointed receiver, qualifying under $25,000 bond. The assets of the company are in the neighborhood of $200,000, with liabilities considerably less. The operation of the company is in Barbour, the offices of the company being in Fairmont.

Birmingham, Ala.—Adams, Rowe & Norman, Inc., is the title of a new corporation, with offices in the Brown-Marx Building, which will devote itself to exporting and obtaining new markets for Alabama coal. Composing the new organization, which has a backing of millions of dollars, are W. Carson Adams, manager of sales of the Alabama Fuel and Iron Co.; G. J. Rowe, vice president and treasurer of the Yolande Coal and Coke Co.; and J. A. Norman, vice president of the Bonnyman-Norman Coal Co.

New York, N. Y.—Notices have been received from the United States Fuel Administration stating that monthly reports from distributors of anthracite and bituminous coal and coke on Forms A, B and C, from Pennsylvania anthracite to operators or sales agents on Form OA, and from railroad coal companies on Form 6, will be discontinued by the Bureau of Investigation, United States Fuel Administration, beginning Feb. 1. Reports of all shipments made during the month of January must be mailed promptly within the time required.

Pittsburgh, Penn.—An enthusiastic meeting of the coal-jobbing interests of Pittsburgh and vicinity was held in the ballroom of the William Penn Hotel on Monday, February 3, which was in the nature of a dinner in honor of George H. Cushing, Managing Director of the American Wholesale Coal Association. About 130 coal jobbers and their operator friends were present. Owing to the illness of A. R. Hamilton, of A. R. Hamilton & Co., who had been selected as toastmaster, it was necessary for Ira E. Bixler, president of the local association, to act in his stead. Mr. Bixler made a brief address of welcome and urged upon those present the necessity of organization, calling attention to the fact that the other branches of the industry had in the past outstripped the wholesalers and that it was necessary for them to protect their interests even as the retail dealer and producer had already succeeded in doing. Mr. Cushing addressed the meeting at considerable length regarding various phases of the present situation in the coal business.

Cincinnati, Ohio—The consolidation of ten operating and marketing coal companies into a single corporation to be known as the Hatfield-Reliance Coal Co. of Ohio, has been effected here by the Fleischmann-Hatfield interests. The new company will have an authorized capitalization of $3,000,000 preferred and $4,000,000 common stock, but it is understood that of this total of seven millions of stock only $3,700,000 will be issued just now. The companies affected are the Reliance Coal & Coke Co., of Cincinnati, and the Hatfield Coal Co., of Covington, Ky., both of which have large distributing organizations; the Lincoln Coal Co., Glomawn Coal Co., Hazard Junior Coal Co., all of Perry County, West Virginia; Reliance Coal & Coke Co., Reliance Iron and Coke Co., Licking Valley Coal Digger Co., West Virginia Workers' Coal Co., Plymouth Coal and Mining Co., all of West Virginia; and the E. J. Hickey Transportation Co., operating boat and barge lines. Pending the completion of the merger, with the election of new officers for the consolidated company, meetings of several of the companies involved were held in Cincinnati on Feb. 4, when officers were elected. The company will organize an extensive distributing system throughout the Middle West to market the large production which it will control.

MARKET DEPARTMENT

Weekly Review

No Life to Coal Market—Many Operations Shut Down—Soft Coal Prices Maintained, While High-Grade Varieties Are Advanced in Price—Await Outcome of Railroad Fuel Argument—Plenty of Anthracite.

THERE is no activity in the coal market. A noticeable feature, however, is the fact that the relinquishment of Government control, instead of resulting in lowered coal prices, has brought about an increase in price of the high-grade bituminous coals. Coal mined in Franklin County, Illinois, has advanced twenty cents a ton, while sales of West Virginia smokeless coals are being made at forty cents above the last-fixed Government price.

So extremely dull is the demand for all kinds of coal that hundreds of operations have been shut down, pending a revival of buying. No such revival is expected much before the first of May, when it is believed that consumers who have been using up their reserves will again be forced to come into the market. The shutting down of the mines has served to tighten the condition of the market, and it is not at all improbable that other grades of coal besides those already referred to will increase in price before the month is out. Wherever sales are reported at considerable concessions from the Garfield prices, investigation discloses that the coals so sold are in small lots and of an inferior grade.

Little contracting is reported for future requirements, the general tendency of large consumers being to await further developments. Another deterrent to active contract inquiry is that the question of what price the railroads are to pay for fuel has not yet been decided definitely. It is understood that the railroads insist on getting their coal supplies at a price out of all proportion to the costs of production, and that the national soft coal operators' association has taken the matter up with Director General Hines.

In years gone by the railroads, by many unfair practices, were enabled to buy their coal for far less than the cost of producing it. The operators, in order to avoid a loss, as a consequence were obliged to raise the price of coal to the public. This the operators refuse further to do, and the outcome of the conferences with the railroad head is being eagerly awaited.

Production of soft coal is still on the decline, the output of the bituminous mines during the week ending Feb. 1 being estimated at 8,345,000 net tons.

The continued prevalence of good weather has caused many of the collieries in the anthracite region to suspend indefinitely. Both dealers and consumers have plenty of coal on hand, and cancellations and suspensions of deliveries are the order of the day. Steam as well as domestic sizes of hard coal are plentiful, though there is less of the former coming to tidewater now because of the falling off in demand.

The output of anthracite coal during the week ending Feb. 1 is estimated at 1,821,000 net tons, exceeding production during the same period of 1918 by 57,000 net tons.

WEEKLY COAL PRODUCTION

Bituminous—The third successive week of decreasing production was recorded during the week of Feb. 1 when the output of bituminous coal declined to the lowest level during the past few years with the exception of Christmas week of 1918. The production during this week is estimated at 8,345,000 net tons and is 893,000 net tons below the production of the week of Jan. 25 and 1,271,000 net tons below the week of Feb. 2 of 1918. The average production per working day during the week of Feb. 1 is estimated at 1,391,000 net tons as compared with 1,872,000 net tons, the daily average for the coal year to date, and 1,744,000 net tons, the daily average for the same period of last year. The production for the coal year to date now totals to 494,081,000 net tons as compared with 460,417,000 net tons for the period Apr. 1, 1917, to Feb. 2, 1918.

Anthracite—Anthracite production during the week of Feb. 1 is estimated at 1,821,000 net tons, a decrease compared with the week preceding of 65,000 net tons, but exceeds production during the same week of last year by 57,000 net tons. The daily average per working day is estimated at 304,000 net tons and for the coal year to date at 312,000 net tons, compared with 317,000 net tons for the same period of last year. Total production for the coal year to date is estimated at 82,363,000 net tons and falls behind production of last year by 1,311,000 net tons.

Carriers' reports for the week ended Feb. 1 show that decreases occurred in all fields, compared with the week preceding. In the central Pennsylvania fields the decrease in cars loaded amounted to approximately 4600; in Ohio to 1700 and in the district including Illinois, Indiana and western Kentucky to 3011.

New England Shipments—Bituminous coal movement to New England continued on the downward grade during the week of Feb. 1, being estimated at 299,308 net tons as compared with 344,112 net tons during the week of Jan. 25. This decrease occurred in both rail and tidewater movements, all ports reporting a falling off in the tonnage loaded.

Tidewater Shipments—Shipments of bituminous coal from the north Atlantic ports and Hampton Roads during the week ended Feb. 1 are estimated at 667,206 net tons and fall behind shipments during the preceding week by 16,788 net tons. Baltimore was the only harbor to report an improvement over the week preceding, while New York and Philadelphia fell behind slightly. The Hampton Roads shipments also fell behind, the decrease at this port amounting to 16,577 net tons.

Beehive Coke—The production of beehive coke in the United States during the week ended Feb. 1 is estimated at 529,000 net tons as compared with 575,000 net tons during the week ended Jan. 25, and as against 468,000 net tons during the same week of 1918. The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production during the week ended Feb. 1 at 295,253 net tons, and the operation of their plants at 75.2 per cent. of full time compared with 74.6 per cent. during the week ended Jan. 25. Improvement is noted in labor conditions. The same operators produced 141,400 net tons of coal.

Byproduct Coke—The production of byproduct coke in the United States during the week ended Feb. 1 is estimated at 554,639 net tons and while approximately 10,000 net tons below the production of the week preceding, exceeded production during the corresponding week of 1918 by 188,000 net tons. The plants of the country were operated at 84 per cent. of their full time during the week as compared with 85.5 per cent. during the week ended Jan. 25. The loss of capacity amounted to 16 per cent. during the week of Feb. 1 and is due to repairs to plants which amounted to 6 per cent. and lack of business which amounted to 5.8 per cent. as compared with 1.4 per cent. during the week previous. Operating conditions changed but slightly in the various states, lack of market being reported for the first time by the operators in Alabama and increased losses of capacity occurring in all the districts reporting lack of market as the limiting factor.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running somewhat less than for the corresponding week of 1918. Road sales for immediate delivery were about the same, compared with the corresponding period a year ago. Our road salesmen are not offering fall lines as yet. Many more merchants are in the market at this time than in recent years, replenishing stocks depleted by excellent retail business. Collections continue excellent.

The Iron Age—Urgent needs are bringing forward delayed buying by the railroads. Besides cars and locomotives, 500,000 tons of rails are counted on. Some rail mills are without orders and none has more than four or five months' bookings. On foreign account 62 locomotives have been sold for Africa and Argentina. Car builders are expecting a release on 20,000 cars for France postponed on the cessation of hostilities. German steel output according to the London cable was about 16,500,000 tons in 1918 or about the same as 1917. A big Continental rail and construction material demand is reported.

Dry Goods Economist—The attitude of labor has engaged the attention of distributors and manufacturers of textiles this week almost to the exclusion of problems more directly connected with merchandising. In numerous and widespread centers operatives have quit work in the effort to enforce their demand for shorter hours with no reduction in wages, while in a few cases the operatives want not only shorter hours but an actual increase in pay. In some cases the operatives' refusal to withdraw their demands was answered by the closing of plants. In few instances have the operatives' demands been granted.

Dun's—Of disquieting features, the existing labor troubles, notably those in Eastern textile centers, are conspicuous, and the percentage of idle machinery has stead-

ily risen, either because of strikes or from the slow development of new orders to replace the expired or canceled Government contracts. Very heavy payments through the banks, as reflected in Clearing House transactions at the principal cities in the United States, continue the rule, total exchanges this week amounting to $6,255,465,712, an increase of 23.3 per cent., as compared with this week last year, and of 0.2 per cent., as contrasted with the corresponding week in 1917."

Bradstreet's—Some important branches of the woolen industry are reported firmly established on the newer basis of time run. Overtime in industry and on the railroads has definitely ended, but reports from steel mills, particularly at the West, is that the wheels are beginning to turn faster in answer to calls from new domestic business. Export trade has livened up a little in lumber, leather, and provisions, but iron and steel are declared to still lag in this respect. In distributive trade, while the general report is that affairs as a whole are still at a waiting stage, there are signs that Spring distribution, especially at the West, is a trifle more active, not so much in textiles as in shoes, millinery, hardware, agricultural implements, and building materials.

Atlantic Seaboard

BOSTON

Situation continues hopelessly dull. More and more difficult to absorb water-borne coal. Operators find situation here hard to understand. Lower rates on barges but no business. Steamer rates unchanged. Action on railroad fuel eagerly awaited. Pennsylvania shippers have ample contracts on file but shipments suspended to such extent that shutdowns are beginning to be the rule. Mills under heavy curtailment. Outlook anything but encouraging. Bottom has fallen out of anthracite market. Retailers put out 50 per cent. normal or less. Many shippers without orders. Price reduction general in Boston.

Bituminous—The current situation here is without any relieving feature. There is now practically no buying interest whatever, and as the season advances the trade realizes more keenly how far off is any material improvement. The current market is simply stagnant and the merest nibbles on the part of buyers are signals for the closest of figuring. Unless for special reasons a purchase is contemplated there is no buying at all. For more than 90 per cent. of the steam-users of New England a very substantial cut in current prices would be no inducement, so heavy are current stocks and so little faith is there in the future of the market. This has been proved time and again the past month, when both all-rail and at tidewater sacrifice offerings have been made in the effort to dispose of distress coal. As low as $1.50 per net ton has been heard on some of the West Virginia grades that are accessible to New York ports and where coal had to be moved in order to obviate heavy demurrage charges under the new rules in force with the Tidewater Coal Exchange. The outlook is for a hopelessly dull market throughout the spring.

The tidewater market is practically bare of inquiry. The regular shippers who normally have staple trade throughout the season are facing almost complete shutdowns at the mines in addition to the steamers under charter that must remain tied up for an indefinite period while the Shipping Board collects its monthly dues on Government form of charter. So difficult is it now for this territory to absorb cargo coal that factors with market coal on their hands are at loss which way to turn. It is reliably reported that a price alongside that is less than the f.o.b. figure at Hampton Roads was the only offer obtainable on such a cargo a few days ago, and at that the barge would have to wait several days for space to be made through daily consumption to take on the coal. In other words, prices have to be shaded nearly $3 per ton in order to induce the purchase of a single cargo, and that illustrates the state of the market in this territory at this writing.

Rates on barges from Hampton Roads that were quoted at $3.50 in the midst of the stringency last summer are now to be had at $2.75 even to points east of Boston, but the modification has little significance because there is such a dearth of inquiry. There is an accumulation of boats at practically every port because charters are so hard to place. Meanwhile steamer rates under the jurisdiction of the Shipping Board are unchanged and there is apparently no prospect of change until Apr. 1, if then. A few of the steamers heretofore in coastwise trade have been chartered to Cuba and to South America, so that today there are probably not so many steamers actually laid up as was the case a fortnight ago.

The attitude of the railroads has always been a big factor in the New England market, whether the latter is dominated by buyer or seller, and this year will probably be no exception. The trade is eagerly looking forward to a decision by the Railroad Administration on this complicated matter, but to judge from the reserves being carried by New England roads and the bargain-counter offers being made them by shippers who have coal they must move the matter is likely to be viewed much less urgently by the railroad authorities than by the coal interests.

Most of the Pennsylvania operators who have regular connections in this market have ample contracts on file, but the latter are useless at this writing because so generally have the consignees been supplied through other channels. Then too, consumption was estimated last year on a war basis and on the basis of a normal winter, and now with abundant water power and widespread curtailment it is physically impossible for a very large number of plants to increase their stocks even if there were an object in doing so. $2.30@2.40 is being freely quoted per net ton on medium-grade coal f.o.b. mines in central Pennsylvania but no business of any moment is reported. On the other hand an increasing number of mines have practically ceased operations. The movement of these coals into New England seems certain to diminish through February and March. No comprehensive business is being looked for now until June, at the earliest.

Anthracite—As orders are filled there is no new business to take their place. There are several houses here who have no unfilled orders on their books. The bottom has certainly dropped out of the anthracite demand for all sizes. The relatively few shipments that are being made contain a large proportion of stove and chestnut, apparently the only sizes that the public is at all interested in taking on. Retailers in all directions report that trade has fallen off at least 50 per cent. and that it is increasingly hard to find consumers willing to accept deliveries. For the most part the last "third" which retailers were restrained from delivering during the summer and fall has proved a myth and does not exist. The extremely mild winter has something to do with it, of course, but the psychology of the situation had also much to do with it.

The retail dealers of Boston reduced prices on Feb. 5 from $12 on broken egg, stove and chestnut to $11 for these sizes, $10 being the new price for pea. By this move the dealers acknowledge there was some ground for the reduction made by one of their number some weeks ago, the announcement of which attracted widespread attention.

NEW YORK

Demand for anthracite nearly at a standstill. Orders scarce and many individual operations reported as closed temporarily. Yards have sufficient supplies for several weeks. Company prices for the domestic sizes prevail. No change in mine prices expected. Bituminous situation quiet, with plenty of coal to meet all needs. Production greatly curtailed and many miners idle. Many loaded boats in the harbor.

Anthracite—There has been no improvement in either the wholesale or retail markets. Demand is practically at a standstill and orders have become so scarce that many of the mines are operating on half time or less. Several of the smaller operations, it is reported, have temporarily closed down entirely due to the lack of demand.

Locally the situation is bad. There is plenty of coal to be had but no buyers. Everybody seems to have sufficient supplies to last until Mar. 1, even if the weather should cause a heavy consumption, and there is no disposition on the part of retail dealers to do any more buying at present.

The differential between the Individual and Company prices no longer exists so far as buying is concerned, as the smaller operator realizes that he can secure orders now only by meeting the company terms.

Nothing definite has been announced concerning the rumor that mine prices might be changed. Some coal men do not expect any change from the present prices, at least not until Apr. 1, and then there are others who believe that instead of the differences between the two prices being equalized there will be the usual spring discount of 50c. per ton. On the other hand there are many who would not be surprised if there were no spring discount. However, no definite announcement is expected for several weeks to come.

The demand for domestic sizes is stagnant. There is no call and the surplus is heavy. Shipments to this harbor continue to average up well with those of previous weeks. Dumpings for the seven days ended Feb. 7 were 5014 cars as compared with 4569 cars the previous week, an increase of 445 cars.

Dealers are not inclined to buy heavily at this time, preferring to reduce their stocks rather than to carry over into the new coal year a lot of high-priced coal. A few days of real winter temperature would, however, stimulate the market.

The demand for the anthracite steam sizes shows no improvement, but the market is stronger because of the suspension of operations in many of the mines, causing smaller shipments. Many operators are taking advantage of the present situation to store these coals, and this tends to decrease the tonnage sent to tidewater. Quotations in Individual coals vary, with heavy concessions heard of rice and barley. Pea coal is practically unsalable, many shippers, according to report, asking for offers. There is no demand for it and the supply is large.

Bituminous—Even with the market quiet the situation is well in hand. With similar conditions existing a few years ago it would be expected that the market would be over-run with coal, but no such condition exists now. There is plenty of coal here to meet all requirements, but the surplus is not so large as to cause a break that would result in mines being willing to practically give their coal away.

Operations have been curtailed and the result has been that the market is not overburdened. One hears of certain grades being offered at concessions below what was the Government's maximum, but that was expected by many shippers. For the high grades these concessions are not so large as for the cheaper coals. This may be due to the demand of large consumers for high-grade coals and the continuance of the Government to take good-sized tonnages.

Operators are not disposed to take orders for Clearfield coals at lower prices than from $2.60 to $2.75 at the mine. They are taking into consideration the cost of production and rather than operate at a loss are inclined to suspend mining until the market is in better condition.

Lack of demand has already been felt in the mining regions and many mines have either been closed down temporarily or are working on a curtailed schedule. In the Fairmont regions it is reported that many thousand mine employees are idle because of the lack of orders.

With the coal year drawing to a close the matter of contracts for next year is attracting some attention. There are numerous inquiries, but it is not likely that either operator or consumer will hurry the signing up for next year's supply. Neither side seems anxious to obligate himself with the market in its present condition. The consumer inclines to the belief that cheaper coal is possible while reports have it that the operator believes higher prices, especially for the best grades will be the rule. There are some consumers who believe that by waiting until about June before signing up for next year's coal they will be able to strike a bargain, while there are others who believe they will do better by buying in the open market.

There are many loaded boats in the local harbor, some of which it is reported have been offered at low prices in order to save demurrage charges. Gas coal is in good supply.

Dumpings of bituminous coal at the local railroad docks for the week ended Feb. 7 were 6779 cars, an increase of 592 cars over the previous week.

PHILADELPHIA

Retail prices for anthracite drop as result of removal of Government supervision over mine prices and surplus of coal. Local market continues quiet. Demand is slow and dealers are not inclined to fill up at present time. Stove and chestnut is heaviest call. Bituminous market "dead." Removal of price supervision makes no difference in local situation. High-grade coal wanted and consumers are willing to pay price.

Anthracite—The removal of the Government regulations of prices on anthracite has resulted in a drop in retail prices in this city, the reduction varying according to size and the proportion of coal purchased by the dealer from individual operators.

The market is quiet. Demand has dropped and buying is slow. Most of the dealers have their bins filled and do not expect they will have to make heavy purchases until spring.

The heaviest call is for stove and chestnut, and this is limited and hardly makes a dent in the stocks available for shipment by the operators. Movement of egg and pea is slow, and shippers find themselves overstocked with these sizes. Reports from nearby counties indicate a better demand than in this city, with prices for individual coals stiffer.

With everybody complaining of the quantity of domestic coals on hand, the supply of the steam sizes is even greater. The curtailed receipts due to the closing down of numerous mines throughout the regions are more than sufficient to take care of all immediate requirements.

Reports from the coal fields indicate a heavy suspension of mining, and unless demand increases a further curtailment may be necessary. On Friday of last week it was reported that 17 mines in the Schuylkill region were idle because of the glut in the market. It was also reported that some of the railroads were considering the laying-off of some train crews because of the lack of shipments.

Bituminous—The situation has not been changed to any great extent since the first of the month when the price supervision was removed by Governmental order. The demand is slow and the supply of coal on hand large. While concessions have been heard of, they are not made for large lots.

Most consumers having plentiful stocks on hand are willing now to buy only high-grade coals and for these are willing to pay substantial prices. The cheaper coals are not in demand unless the buyer is hard pushed and has been unable to secure the better qualities.

BALTIMORE

Soft coal market remains heavily overstocked, and prices on forced sales are much off old Government maximum. Anthracite in plentiful supply, and some dealers hard pressed to find places to put it. Independents offer inducements.

Bituminous—The bituminous market here is more than liberally stocked at present. It is hard now for mines to place any but the better coals. The tidewater terminals are all jammed with loaded cars. Some forced sales in this market are being made much off the old Government maximum. For the first time there was talk of offerings of fuel around the $2 mark, the coal thus pushed being from the Fairmont district. The less desirable coals running on pool No. 18 here too were offering cheap in many cases, and some sales were recorded on a mine basis of $2.20. Better grade coals generally ranged all the way from $2.50 to $2.75 mine basis for the most part. An effort is being made to clean up the congestion here by placing the coal with plants that can store a little more ahead. It may take a few weeks, however, to get things so far straightened out as to give a healthy market again. Numerous mines remain closed, and there is some talk of labor uneasiness as a result. Labor in some sections is finding it hard to understand that high wage scales do not necessarily mean continuous work.

Anthracite—Hard coal has poured in liberally of late and dealers here, in the face of the light demand due to the continued mild winter, are in some cases hard put to find outlets. Some with limited yard capacity have coal awheel that they do not know what to do with. Dealers who are well stocked now are cautious in ordering as they fear being caught by a change of prices at the mines. There has been talk that the company mines may advance rates 25c. to 50c. and that the independents will then sell at the same rate. As a matter of fact independents are already offering inducements for orders, waiving in many cases the 75c. difference allowed by the Government formerly, and agreeing to sell from Feb. 1 at any rate that may be established by the company mines. Retailers are moving slow in all purchasing, however, and the market is generally listless.

Lake Markets

PITTSBURGH

Asking prices on Government basis. Scarcely any contracts. Demurrage coal at cut prices. Operations at 30 to 35 per cent.

The advanced prices published by Pittsburgh district coal operators, on the basis of $2.50 for mine-run, 15c. less for slack and 10c. more for ¾-in., proved not to be even a seven-days' wonder but rather a two or three days' wonder, and they are now practically forgotten. The asking price for mine-run is $2.35, the former Government maximum, but bids at less are frequently accepted, particularly in the case of coal on track and requiring immediate sale to avoid demurrage. Demand is so light that such coal is an important market influence, though the quantity involved would be quickly absorbed in a market of normal dimensions.

Operators are looking for the curtailed output—30 to 35 per cent. of capacity—and a growing demand from consumers to right the situation and put the market on a steady basis. They insist that cost of production at the lowest cost mines is not much under the Government figure and at many small mines is above it, also that no one is going to sell coal at a loss. Buyers do not regard arguments based on cost figures as conclusive, and accordingly are holding off.

The contract season is on, but scarcely any contracts are being made. One contract, however, is definitely reported, 3000 tons monthly of ¾-in. gas coal over the twelvemonth at $2.60, the full Government limit. The contract probably represents the exception rather than the rule. It is improbable, however, that there will be much shading of prices in the case of contracts, for a time at least, but spot lots that must be moved may go at any figure.

The market is quotable at about the following range, depending largely on grade, but the higher figures being fairly well maintained as asking prices on contracts: Slack, $2@2.10; mine-run, $2@2.35; ¾-in. gas, $2.45@2.60, per net ton at mine, Pittsburgh district.

TORONTO

Market quiet and featureless. Drop in price of anthracite. Industrial reconstruction slow. Bituminous little in requisition.

The coal market remains quiet and featureless, and dealers are doing little more than mark time. Such orders as are being received are mostly from the class of consumers who buy from hand to mouth. The price of anthracite has been reduced from $12 to $11.50 per ton, otherwise prices remain unchanged. There is no noticeable improvement in the demand for bituminous, the movement of which is likely to remain slow for some time to come. It is now fully apparent that industrial reconstruction, which was expected to take place rapidly, will be a gradual process, as but little actual progress is being made in that direction—manufacturers generally pursuing a conservative policy as regards projected changes and expansions.

BUFFALO

No improvement in coal situation. Anthracite orders being cancelled. Prices being held by shutting down mines. Jobbers find trade past managing. Prepaying freight charges.

Bituminous—The trade remains quite as dull as formerly. The weather has upset everything. Other industries as well as coal are disturbed by it, and trade is affected. The warm winter would have been welcomed a year ago, but now it has spoiled all sorts of calculations. Consumers of coal are using less fuel than they would in an ordinary winter. They have more coal on hand than they have any use for, and sometimes more than they can well store.

The mines are so far in command of the situation, for they shut down as often as the coal fails to sell. The new order, that does not permit the reconsignment of coal is likely to help the situation, so far as the mines are concerned, but it hurts the jobber; and he is badly enough off now. If coal must be shipped from the mine direct to the consumer it will not stand about waiting for a market. Buffalo has had little unsold coal on track this winter, and the little that was caught in that way suffered. Some of it sold for freight or even less.

Now comes the order to prepay the freight on all slack coal that is shipped into Canada by the Niagara or St. Lawrence River routes. This means that the shipper must put about twice as much money into the business as formerly, but it is done to protect the railroads from coal that is left on their hands. Some members of the trade see justice in it, though it will be opposed by all shippers. The dropping of the Government arbitrary prices has made no particular change in bituminous prices, which remain as before.

Anthracite—Distributors are still saying that consumers are not well stocked up here, but they are also aware that with a few days more of mild weather they will refuse to stock up at all, and will buy by the ton or two. There is still time for considerable winter, though not for any such winter as that of last year. At present many orders are being cancelled.

While the prices of anthracite are being held firmly by the railroad-controlled companies, the extra price allowed to the independents has been dropped, still the demand is light. Consumers complain that they must pay about twice what they did a few years ago, but it is easy to show that the cost of producing and marketing coal has also doubled lately. Word comes that preparations are being made for a still further advance in the freight rate, and possibly of the mine price also.

CLEVELAND

Prices of bituminous coal have stiffened, if anything, since Government control has been completely relinquished. The matter of price, operators declare, is entirely dependent upon the action of the Railroad Administration. More anthracite is being received, and a cut of 40c. in retail prices is due.

Bituminous—The larger operators have declared war on the "bolsheviks"—the smaller operators and jobbers who are undercutting prices. Asserting that price-cutting cannot stimulate business, and that it only weakens the indusry's contention that high labor and transportation charges have seriously impaired the margin of profit, the larger interests are refusing, as a whole, to make concessions and are spreading propaganda to this effect. The result has been smaller offerings of standard No. 8 coal underneath what was the Government maximum.

As has been the case for some time, mine-run can be had by "shoppers" for from $2 to $2.35. Most of this continues to be "car service" coal, in which the price is almost wholly a matter of bargaining between seller and buyer. The standard quotation on No. 8 coal remains $2.35. Contract coal is going at this figure, and the larger interests claim to be intending to stick to it until Apr. 1. Prices for the coming year will be regulated by the price the Railroad Administration offers, it is believed. As proof of this, lake coal will not be priced until the railroads take a stand. It is believed that if $2.35 is not maintained $2.15 will be the minimum offered.

Probably one-third of the normal tonnage of coal northern Ohio consumes now is coming into the district. Half-time now is a good average at southern and eastern Ohio mines. This is held not half bad in the light of adverse trade conditions. Mine workers admit they have no grounds for complaint, yet the idleness is not to their liking. No outright offers to shade the present scale are reported, but it would not be surprising if some operators sounded out labor on this proposition shortly.

From some quarters comes the advice that steam-coal users had best take advantage of the present lull and stock up in anticipation of protracted negotiations between operators and the mine workers when the wage scale question is opened. Whether this is sales-promotion talk or a sincere warning is difficult to determine. No sales for this reason are reported, for those who heeded the Fuel Administration's warning and laid down coal for this winter are willing to take their chances next time, they say.

The retail coal trade continues stagnant. Some Pocahontas is expected soon after Feb. 15, and it will be priced at $7.50 for the prepared sizes. It will compete with coke at $12.15 and West Virginia splint at $7.10. A fair demand for Pocahontas is anticipated, for long-time users say they will abandon substitute anthracite or bituminous at the earliest possible moment. Pittsburgh coal retails, delivered, at $6.35. The larger retailers have not yet reduced appreciably, though smaller dealers are offering job lots of "car service" coal at reductions of fom 50c. to $1.

Anthracite—Egg now is as plentiful as the furnace grades, egg retailing for $11.25 and chestnut for about $11.55. These prices will be reduced 40c. in a few days, the high-priced independent supplies being about exhausted. While anthracite is by no means plentiful, all the demand for it is being met.

Lake Trade—As the winter wears on and the dock piles at the head of the lakes melt much slower than usual, talk of a later opening becomes more prevalent. Few cargoes will be going up the Great Lakes before the first week in May, it now appears. Lake coal is being placed, but price is being deferred. Many lake shippers have now come out for restoration of the original demurrage rules, which provided seven days free time and demurrage thereafter at $1 a day. The free time has been cut twice—first to five days and then to three. At

three days individual shipping cannot be done, is the claim. The lake shippers' committee is awaiting word from Washington setting the date of the conference with the Railroad Administration in regard to demurrage revision.

DETROIT

With lower temperatures encouraging the hope for more active domestic buying, many Detroit retailers fear open market conditions will bring in a flood of coal, hindering sale of their heavy stocks.

Bituminous—Burdensome stocks of bituminous coal held by local industrial plants and by a large proportion of the retail dealers are still a source of uneasiness in the Detroit trade. Because of these stocks the volume of new buying is small. The users of steam coal are not cutting down the stocks on hand as rapidly as had been anticipated. Transition from war to peace conditions is accompanied by a general reduction of activity in manufacturing lines, due both to Government delays in settling accounts with the contractors.

A considerable part of the business now coming to jobbers and wholesalers is derived from the steam plants that customarily buy in small amount, practically on a hand-to-hand basis, because of their lack of facilities for storage. Prices are said to be holding fairly steady at the Government level, except in a few instances involving mine-run stock. One concern is reported to have sold some of this class of coal at about $5.60 delivered.

The problem presented to many of the retailers by removal of the Fuel Administration's restrictions is a serious one. Unsold stocks of bituminous fill their yards. A considerable part of it is rated as inferior in quality and much of the stock is mine-run, which the dealers bought when a more desirable coal for domestic use could not be had. Unusual weather conditions have prevented realization of the active demand that was expected. The dealers are still hopeful of getting this stock into consumers' hands if the weather will only remain cold long enough to stimulate buying. They realize, however, that their situation will be made precarious should shipments of a better quality of coal come into Detroit in any quantity.

Anthracite—Mild weather has made possible large conservation of the anthracite so far received and most of the dealers have a small supply on hand. Because of their desire to reduce troublesome stocks of bituminous, before the end of the coal year, it is probable no very strenuous effort will be exerted to bring into Detroit a larger amount of anthracite than the city's allotment from the Fuel Administration.

COLUMBUS

There is practically nothing doing in the coal trade. Business is at a low ebb, and there is little in the future to encourage the coal men. Steam stocks are large and retailers are only buying in small lots. Prices are still unsteady.

The coal trade in Ohio has now reached the lowest ebb in the memory of many of the older members of the industry. Demand is at a minimum, and little is expected within the coming month. The raising of the zone restrictions has not caused much demand for coal, as stocks were generally sufficient for the present. Some Pocahontas has been moving into localities where it was zoned out, but this is not expected to last for any time. Retailers are loath to increase stocks in view of the exceedingly warm winter. In fact they are inclined to wait until their stocks are quite low before replenishing. Retail prices are generally well maintained, but there is enough cutting to make the market unstable. Householders have sufficient stocks to go through the winter, and the indications appear that some will be carried over. Little anthracite is now coming into this territory.

The steam trade is quiet in every respect. Buying is limited to actual needs, which are small, as most of the larger consumers have stocks to last for several months. The change from war to a peace basis is not going on rapidly, and that is holding up the fuel business. Public service concerns have sufficient stocks of fuel, and the same is true of public institutions. In fact little is expected in the steam trade until after Apr. 1. Screenings are plentiful and cut prices for that grade are the rule.

Production is at a low ebb in all of the producing fields of the Buckeye state. This is due partly to lack of proper equipment. The railroads serving the Hocking Valley field have been robbed of their hopper cars and have an oversupply of huge gondola dump cars, which cannot be used in the domestic trade to advantage. Thus some orders are missed that might be filled otherwise. It is estimated that the Hocking Valley, Cambridge and Crooksville fields are now down to about 25 per cent. of normal. Pomeroy Bend is not much better off, and eastern Ohio is credited with about 30 per cent.

Prospects for the lake trade for the coming season are not as bright as in former years. This is due largely to the fact that a large tonnage will be carried over on the docks, and that ore shipments will be delayed. The opening is expected to be late.

CINCINNATI

Dullness continues to feature the entire market, consumption being largely from storage supplies or on contract deliveries. Competition for business will be keen during coming season.

The local market has not differed materially from its former status during the past week. The removal of the restrictions imposed by the zone system was greeted by the trade with considerable relief, naturally, as it opens a way for the return of business with the Middle West and more distant territories.

However, as already suggested, conditions just now are such that the return of this business cannot be immediately expected, as the same general conditions which have affected business in this immediate vicinity exist also elsewhere, and any large shipments of coal into the western markets would merely result in further complicating an already difficult situation.

Producers and agents here are preparing to go vigorously to work in their old territories, in order to secure for the future whatever business may be available to them. They understand fully the inadvisability of imparting a false stimulus to a dead market by means of drastic price-cutting, and it may be predicted that nothing of this sort will be resorted to; but every legitimate means of securing business will certainly be used in the coming month by concerns with production to dispose of, as a matter of course, and this means that the competition for 1919 contracts will be as keen as the trade has ever witnessed.

LOUISVILLE

Continued mild weather holding back domestic demand. Industries overstocked, general movement dull. Mines operating two to three days, with many small mines down.

There has been no material change in the general situation in the Kentucky coal industry during the week. Weather conditions are about the same as they have been for the past three or four months, resulting in retailers doing a light business. Industries are generally overstocked and are not buying.

Good domestic coal is in slightly better demand than other varieties, and numerous operators are getting 15c. per ton over former maximum prices for domestic. Steam coal, especially screenings, is hard to sell and is being shaded as much as 50c. a ton by many operators. It is claimed that the Southern markets are generally stronger than the Northern markets, where more price cutting is being done. South of the Ohio River the operators, retailers and jobbers are making a harder effort to maintain prices.

With the lifting of the zone regulations some operators are again able to continue shipments on old contracts, but the contracts are not of much advantage as the customers are stocked up on Fuel Administration coal.

It is claimed that a few operators have been shading contract prices slightly in order to retain good will of industrial consumers who are tied up on contracts, but as a rule an effort is being made to hold contract prices. Practically no new contracts are being made at the present time.

Eastern Kentucky operators who were practically out of the Louisville market in many instances during the past year are again making a hard drive for local business. The western Kentucky operators who had things almost their own way in Louisville are making a fight to hold their gains.

Many of the mines in both fields are down, some of the big western Kentucky mining companies only operating a part of their mines, and not full time in these. Few mines in eastern Kentucky are running more than three days a week, and any number of small mines are down indefinitely.

Railroads are practically out of the coal market, some roads even curtailing their requisitions from contract mines to 50 per cent. of the output. Under such conditions the mines without railroad contracts have no chance for rail coal business.

BIRMINGHAM

Steam trade in unsettled condition with little demand for spot coal. Government schedules being maintained as minimum prices. Strong domestic demand and short supply cause prices to advance.

Inquiries for steam coal in this market have been light for the past week and little new business has been booked. Consumers who are not tied up in contracts seem disposed to await the trend of affairs for a while at least, while producers have assumed an attitude of "watchful waiting" and are holding firmly to Government schedules in effect at the close of January. It is stated, however, that when the market again becomes active that there will be an advance in mine prices on some grades of steam fuel. Contract coal is moving normally.

The lifting of the ban on coal prices was followed by an advance of from 20 to 65c. per ton on domestic coal at the mines. The shortage in this grade of fuel, which has been in evidence since Apr. 1 last, still exists to a marked degree and there is an insistent demand for every ton obtainable.

The future of the trade is viewed optimistically by sales managers and brokers, and special attention is to be given to the establishment of markets for Alabama coal in the gulf ports and in the South American industrial centers, as announced by Adams, Rowe & Norman, Inc., Knox Conville, who for a number of years has been manager of sales for the Pratt Consolidated Coal Co., the largest producers of commercial coal in the district, and H. S. Hall, well-known in the local trade, have established a sales agency under the title of Conville & Hall, and will handle the output of the Pratt company and other mines in the district.

Coke

CONNELLSVILLE

Demurrage coke factor in spot market. No inquiry on contract. Old contracts under adjustment. Consumption and production decreasing.

While Connellsville coke operators have been endeavoring to curtail production to the continually decreasing demand, they have hardly been able to keep pace, and this has resulted in there being considerable tonnages of coke loaded on track and requiring shipping instructions to avoid payment of demurrage. Furnaces have been well supplied with coke, cars at stacks awaiting unloading and with plenty more on the way, so that it has been difficult to find a buyer for coke at any figure. There are prompt lots of furnace coke, or alleged furnace coke, offered at all the way from $4 to $5, and the usual claim is made that the lower priced material is not standard. Doubtless this is altogether true, for during the war a great deal of coke was made that was far from standard, the difference being that at that time it was shipped to furnaces billed as furnace coke at $6 and was accepted and paid for as such. For strictly first-grade coke furnace may be quoted at $5 and foundry at $6 per net ton at ovens, spot or prompt shipment. There is no contract market as there is no inquiry.

The coal outlook is that relatively high prices will continue, particularly for special grades of coal, gas and byproduct. With so many byproduct ovens completed of late there is a large excess of coking capacity, and with high prices obtainable for byproduct coal the Connellsville region is likely to ship raw coal largely, and sell what coke it can at the bare cost of coking, above the market value of the coal.

Many contracts for furnace coke requiring prices to be adjusted after the disappearance of Government control have been set at $5.50 for February deliveries. The settlement is now admitted to have been rather high, and the furnaces will probably get something in return when March prices are set. The other class of contracts, those that called for "last Government price," are not proving such an asset to the operators as the operators had expected, since it has now become rather generally recognized that some concessions will have to be made from the contract terms, otherwise the furnaces holding the contracts are likely to go out of blast and take no coke at all.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Feb. 1 at 262,644 tons, a decrease of 14,680 tons, and raw coal shipments at 171,399 tons, a decrease of 18,308 tons.

Buffalo—The coke trade is dull. Some say that all grades of it are down, but as a rule it is held that only the off grades are materially affected. Any coke that is used for fuel is hard to sell, but spot foundry is still bringing full $7 per ton for 72-hour at the best ovens. It is expected that the iron furnaces will run strong as soon as the business of the country is back to normal activity, but until it is there must be a falling off of consumption.

Middle Western

GENERAL REVIEW

Prices advance on high-grade Illinois and Indiana coals. Steam trade inactive, with little domestic moving. Eastern coal being kept out of Mid-West market.

Contrary to the general opinion of the average coal purchasing agent, coal prices, effective Feb. 1, 1919, advanced in Illinois and Indiana, rather than declined, as had been perhaps too confidently expected by the buying public. It is true that only the highest grade coals produced in the two states just mentioned are influenced by an advance, but it is a healthy sign, as it shows pretty conclusively that the operator does not intend to go back to pre-war price-cutting conditions. Generally speaking, the advance amounts to 20c. per ton on the prepared sizes. No increases have been made in mine run or screenings, although it is generally predicted that steam coals will advance perhaps 10c. or 15c. per ton, in order to keep in line with the prepared sizes.

It is a remarkable thing that the operators have been able to put this increase in effect, especially in view of the fact that the coal market is weaker than it has been in the last four or five years. It shows, among other things, that through Government control, the operators have learned to figure their costs accurately. Furthermore, they have been pretty well taught the folly of indiscriminate price cutting.

The steam trade remains inactive, with little hope for the immediate future. There are two or three reasons for this. The first is that practically all manufacturers are awaiting developments, and consequently either closing their plants or working only a fraction of the week. How long this state of affairs will continue is open to debate. The second reason for a dull market is that the big buyers of steam coal are waiting to see what sort of a deal the operators will be able to make with the railroads, as it is generally conceded that all big contracts will be patterned after railroad contracts, especially in regard to price. It is hoped that the railroads will be brought to see the light, as there is little justice in selling coal to them at cost or below, and charging the small buyers cost plus a sum large enough to maintain a fair average of profit on all sales. The third reason for a dull steam coal market is that a very substantial tonnage of coal still remains in storage. For instance, one plant in Northern Michigan, normally using 40,000 tons per year, has on the ground approximately 23,000 tons.

The domestic coal situation remains a weather proposition, and consequently, on account of the mild spring days we have had throughout the territory, but little domestic coal is moving. One surprising feature has developed, however, with the lifting of zone restrictions, and that is very little Eastern coal is moving into the Mid-West territory. The retailers have made an organized effort to keep Eastern coal out until such time as their stocks of Indiana and Illinois coals have been depleted. If the territory enjoys a three- or four-week period of cold weather, it will probably bring about an influx of high-grade Eastern coal.

CHICAGO

Prices being maintained, except on off-grade coals. High grade coal prices advanced. Plenty of anthracite available.

In Chicago, coal prices are holding firm, with the exception, of course, of the off-grade coals that have been selling at a discount since last August. The domestic trade was surprised to hear of the advance, effective Feb. 1, decided upon by the Franklin County operators. They were still more surprised to learn that other groups of operators in Southern Illinois and Indiana had followed the lead and also advanced their prices. It is pretty generally conceded that the coals affected by the advance are worth at least 20c. per ton more than the ordinary Indiana and Illinois product, worth more from both the standpoint of quality and preparation.

The mild weather in Chicago has had a big bearing on the present market, and it is felt that a continued spell of cold weather will stimulate production to at least 60 per cent. As it is now, the factories are burning much less coal than normally, and the householder is doing the same thing.

Anthracite coal has ceased to be a "news feature" in market reports, as all the hard coal wanted is easily obtainable.

MILWAUKEE

Advent of colder weather injects a little animation into a dejected market. City and country orders more encouraging. No indication of a break in prices.

A few days of near-zero weather along Lake Michigan, and colder blasts, amounting to a blizzard in some sections of the immediate interior, have served to inject a spasm of life into the coal market, which has been in the doldrums thus far this winter. Orders from both city and country are more encouraging than they have been for weeks. The future of the market depends altogether on the weather. Should another protracted mild spell ensue, it would have a demoralizing effect, as dock companies would have to count on retaining considerable holdings at the end of the coal year on Mar. 31.

At present there are no indications of a decline in prices, which would mean losses to the large dealers. As one distributor put it: "All the coal in Milwaukee was purchased at a 'peak' market. In many cases transfer to the city was made under severe difficulties, and often only through the aid of the fuel administration. The coal cannot be sold lower than existing rates." However, the future of bituminous coal prices rests with western producers, as jobbing and retail prices must be governed by what is paid at the mines. If the mine companies begin cutting there is bound to be a break in soft coal.

Dealers have been allowed a margin of $2.25 for handling each ton of coal other than Illinois. For handling Illinois coal $3.05 has been permitted, because of the greater shrinkage incurred during the process of handling the Illinois product. Illinois prepared sizes are now held at $7.90 carried in. Hocking lump and stove sell for $8.40 and splint lump and stove and Kentucky lump and smithing at $8.90, also carried in.

Anthracite prices continue without change. Chestnut is scarce, however, and commands $13 per ton in bins. Coke is also firmly held.

ST. LOUIS

A continued lagging market with warm weather and no demand of any kind. Cars plentiful and movement good. Mines working one and two days a week. Country demand light.

Warm weather continues and the market is lifeless. There is no domestic demand to speak of except in small quantities here and there, and the steam demand is almost nothing.

The larger plants that are running are using their storage supplies, and there are many plants that are running short time or not at all. There seems to be a sort of business depression in general so far as the manufacturing interests are concerned, due to the stopping of war activities. This promises, however, to be shortlived, and industrial conditions ought soon to renew their normal position. The country demand on all grades is extremely easy. What little coal is moving out is usually forced.

The Standard field still continues to sell coal for below production cost in a general way. Screenings are down to about $1.10, 2-in. lump from $1.50 to $1.75, and 6-in. lump from $1.75 up, with mine-run at about $1.65 to $1.75.

There is a little railroad coal moving out of this district, but the tonnage is small. The operators are facing critical times on account of lack of tonnage, and with growing dissatisfaction among their men. The mines are working from one to two days a week as a rule, and some mines not that much.

In the Mt. Olive field the working conditions are not much better than in the Standard field. There is a fair movement of this coal northwest, and a little railroad tonnage, but the amount of coal from this field coming into the St. Louis market is extremely light. The prices, however, are pretty well maintained, the Government maximum of $2.55 practically prevailing. Screenings are weak and selling below the Government price slightly. There is dissatisfaction here among the miners on account of insufficient work.

In the Carterville field, the Williamson and Franklin Counties, as well as the Du Quoin field, the overproduction continues to increase and the mines are idle on account of lack of orders for all sizes. The steam sizes, however, are the most troublesome. Few mines in this section are working full time.

The price here since the first of the month on the Franklin County coal has gone to $2.75 on domestic sizes. In the Williamson and Franklin County fields some of the operators, fearing Government action, are sticking to the Government price of $2.55, while a few of them have raised to the $2.75 price with the Franklin County operators.

Working time is sufficient in this field to keep the miners pretty well satisfied although the operators claim that they had to raise the price in order to cover the cost of production by the shorter working time and the increasing overhead.

There is a small tonnage of smokeless coal, perhaps from 15 to 25 cars in all, that have been ordered for St. Louis. Anthracite continues to come in in fairly good volume, but there is no local demand for any of the sizes.

There is no Arkansas moving in and coke shipments are almost at a standstill.

The market here, with the exceptions as noted above, is as follows:

	Mt. Olive and Staunton	Standard	
Franklin County:			
Prepared sizes (lump, egg, Nos. 1 and 2 nut)	$2.75	.....	.....
Williamson County:			
Prepared sizes (lump, egg, nut)	$2.55	$2.55	(As noted
Mine-run	2.20	2.20	above)
Screenings	2.05	2.05	.....

Williamson-Franklin rate to St. Louis is $1.10; other rates, 95c.

General Statistics

NORFOLK & WESTERN COAL TONNAGE

Below is given a statement of the coal tonnage from mines on the Norfolk & Western R.R. and from other railroads, for the month of December, 1918:

From	Net Tons
Pocahontas field	966,141
Tug River district	194,455
Thacker district	191,253
Kenova district	60,284
Clinch Valley district	97,433
Other Norfolk & Western fields	7,851
Total Norfolk & Western fields	1,517,417
Williamson & Pond Creek R.R.	155,335
Tug River & Kentucky R.R.	44,520
All other railroads	97,956
Grand total	1,815,228

GEOLOGICAL SURVEY'S FIGURES ON COAL COKE OUTPUT IN 1918

Bituminous coal production in 1918 was nearly 35,000,000 tons greater than that of 1917. The Geological Survey has compiled the following statement of production, by months:

Months	1917	1918
January	47,967,354	42,607,206
February	41,352,711	44,384,957
March	47,868,652	48,631,115
April	41,854,320	46,590,570
May	47,086,452	50,927,195
June	46,824,646	51,758,214
July	46,291,572	55,587,312
August	47,372,226	55,732,092
September	45,107,956	51,757,334
October	48,337,726	52,885,513
November	47,689,801	44,386,987
December	44,037,147	40,634,525
Total	551,790,563	585,883,000

Coke production in 1918 exceeded that of 1917 by slightly more than 1,000,000 tons. The following table shows production by months for the two years:

	Beehive		Byproduct	
Months	1917	1918	1917	1918
Jan.	2,923,056	2,242,362	1,787,850	1,649,819
Feb.	2,489,888	2,234,281	1,806,773	1,562,056
Mar.	3,138,977	2,630,433	1,813,435	2,051,206
Apr.	2,813,935	2,580,931	1,859,278	2,021,437
May	2,861,364	2,757,719	1,879,268	2,139,204
June	2,754,897	2,712,726	1,880,335	2,092,155
July	2,753,902	2,813,910	1,882,200	2,300,673
Aug.	2,649,755	2,657,022	1,914,450	2,387,675
Sept.	2,727,367	2,570,238	1,918,714	2,410,798
Oct.	2,780,436	2,611,885	1,898,192	2,563,183
Nov.	2,677,284	2,339,197	1,899,526	2,523,746
Dec.	2,596,687	2,255,296	1,899,259	2,562,048
Total	33,167,548	30,406,000	22,439,280	26,264,000

Light rails, 12 to 14 lb.	3.09 (100 lb.)	3.125*	3.09 (100 lb.)	49.00
Light rails, 25 to 45 lb.	3.00 (100 lb.)	3.125*	3.00 (100 lb.)	30.00

*Per 100 lb.

OLD MATERIAL—The prices following are per gross ton paid to dealers and producers in New York. In Chicago and St. Louis the quotations are per net ton and cover delivery at the buyer's works, including freight transfer charges:

	New York	Chicago	St. Louis
No. 1 railroad wrought	$18.50	$17.00	$17.00
Stove plate	14.50	17.50	16.00
No. 1 machinery cast	17.00	22.00	20.00
Machine shop turnings	10.00	8.50	7.50
Cast borings	10.50	11.50	10.50
Railroad malleable cast	14.50	16.50	17.00

COAL BIT STEEL—Warehouse price per pound is as follows:

New York	Cincinnati	Birmingham	St. Louis	Denver
$0.12	$0.16½	$0.18	$0.13	$0.18½

DRILL STEEL—Warehouse price per pound:

	New York	St. Louis	Birmingham
Solid	16c.	13c.	15c.
Hollow	24c.	...	...

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh; basing card of Jan. 1, 1919 for steel pipe and for iron pipe:

BUTT WELD

Steel Inches	Black	Galvanized	Iron Inches	Black	Galvanized
⅛, ¼ and ⅜	47%	20½%	¾ to 1¼	36%	20%
½	51%	36½%			
¾ to 3	54%	40½%			

LAP WELD

2	47%	34½%	2	29%	15%
2½ to 6	50%	37½%	2½ to 4	31%	18%

BUTT WELD, EXTRA STRONG PLAIN ENDS

⅛, ¼ and ⅜	43%	25½%	¾ to 1½	36%	21%
½	48%	35½%			
¾ to 1½	52%	39½%			

LAP WELD, EXTRA STRONG PLAIN ENDS

2	45%	33½%	2	30%	17%
2½ to 4	48%	36½%	2½ to 4	32%	20%
4½ to 6	47%	35½%	4½ to 6	31%	19%

Stocks discounts in cities named are as follows:

	New York Black	New York Galvanized	Cleveland Black	Cleveland Galvanized	Chicago Black	Chicago Malvanized
⅛ to 3 in. steel butt welded	43%	27%	43%	26%	44.9%	29.9%
3½ to 3 in. steel lap welded	38%	23%	39%	23%	40.9%	26.9%

Malleable fittings. Class B and C, from New York stock sell at list + 15%. Cast iron, standard sizes, 10% off.

WIRE ROPE—Discounts from list price on regular grades of bright and galvanized are as follows:

	New York and St. Louis
Galvanized iron rigging	+17½%
Galvanized cast steel rigging	+2½%
Bright plain rigging	30%
Bright cast steel	17½%
Bright iron and iron tiller	List

STEEL SHEETS—The following are the prices in cents per pound from jobbers' warehouse at the cities named:

	Pittsburgh, Mill, in Carloads	New York Current	New York One Month Ago	New York One Year Ago	Cleveland Current	Cleveland One Year Ago	Chicago Current	Chicago One Year Ago
*No. 28 black	4.70	6.22	6.22	6.45	5.75	6.45	6.22	6.45
*No. 26 black	4.60	6.12	6.12	6.35	5.65	6.35	6.12	6.35
*Nos. 22 and 24 black	4.55	6.07	6.07	6.30	5.60	6.30	6.07	6.30
Nos. 18 and 20 black	4.50	6.02	6.02	6.25	5.50	6.25	6.02	6.25
No. 16 blue annealed	4.10	5.37	5.37	5.65	4.95	5.65	5.37	5.65
No. 14 blue annealed	4.00	5.27	5.27	5.55	4.85	5.55	5.27	5.55
No. 10 blue annealed	3.90	5.17	5.17	5.45	4.75	5.45	5.17	5.45
*No. 28 galvanized	6.05	7.57	7.57	7.70	7.15	7.70	7.57	7.70
*No. 26 galvanized	5.75	7.27	7.27	7.40	6.85	7.40	7.27	7.40
No. 24 galvanized	5.60	7.12	7.12	7.25	6.70	7.25	7.12	7.25

* For painted corrugated sheets add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gages; for galvanized corrugated sheets add 15c., all gages.

SHOP SUPPLIES

NUTS—From warehouse at the places named, on fair sized orders, the following amount is deducted from list:

	New York Current	New York One Year Ago	Cleveland Current	Cleveland One Year Ago	Chicago Current	Chicago One Year Ago
Hot pressed square	$0.80	$1.00	$1.25	$1.40	$0.98	$1.05
Hot pressed hexagon	80	1.00	1.05	1.20	.78	.85
Cold punched square	2.50*	1.00	.75	.75	1.00	1.00
Cold punched hexagon	2.50*	1.00	.75	.75	1.00	1.00

* List plus.

Semi-finished nuts sell at the following discounts from list price:

	Current	One Year Ago
New York	50—10%	40%
Chicago	50%	50%
Cleveland	50—10%	60%

MACHINE BOLTS—Warehouse discounts in the following cities

	New York	Cleveland	Chicago
⅜ by 4 in. and smaller	40—10%	40—10%	40%
Larger and longer up to 1 in. by 30 in.	20—5%	20—5%	25—5%

WASHERS—From warehouses at the places named the following amount is deducted from list price:

For wrought-iron washers:
New York..$1.25 Cleveland..$1.25 Chicago..$1.75

For cast-iron washers the base price per 100 lb. is as follows:
New York..$6.00 Cleveland..$4.25 Chicago..$4.50

RIVETS—The following quotations are allowed for fair sized orders from warehouse:

	New York	Cleveland	Chicago
Steel ⅜ and smaller	40%	45—5%	40%
Tinned	30%	45—5%	40%

Boiler, ¾, ⅞, 1 in. diameter by 2 in. to 5 in. sell as follows per 100 lb.:
New York..$6.60 base Cleveland..$5.15 Chicago..$5.67 Pittsburgh...$4.65

Structural, same sizes:
New York..$5.67 Cleveland..$5.25 Chicago..$5.77 Pittsburgh...$4.75

CONSTRUCTION MATERIALS

LINSEED OIL—These prices are per gallon.

	New York Current	New York One Year Ago	Cleveland Current	Cleveland One Year Ago	Chicago Current	Chicago One Year Ago
Raw in barrel	$1.49	$1.31	$1.65	$1.35	$1.66	$1.32
5-gal. cans	1.74	1.41	1.80	1.50	1.86	1.45

12½-lb. keg	13.50	15.00	12.75	13.00	13.50	12.50
5-lb. cans	15.00		14.25	14.00	15.00	14.50
1-lb. cans	16.00		14.25	14.50	16.00	14.50

500 lb. lots less 10% discount. 2000 lb. lots less 10–2½% discount.

COMMON BRICK—The prices per 1000 in cargo or carload lots are as follows:

Cincinnati	$15 and 16	Birmingham	$15.00
St. Louis, salmon	12.00	Denver	12.00

PREPARED ROOFINGS—Standard grade rubbered surface, complete with nails and cement, costs per square as follows in New York, St. Louis, Chicago and San Francisco.

	1-Ply C.l.	1-Ply L.C.l.	2-Ply C.l.	2-Ply L.C.l.	3-Ply C.l.	3-Ply L.C.l.
No. 1 grade	$1.35	$1.60	$1.70	$1.95	$2.05	$2.30
No. 2 grade	1.20	1.45	1.50	1.75	1.80	2.05

Asbestos asphalt saturated felt (14 lb. per square) costs $5.00 per 100 lb.

Slate-surfaced roofing (red and green) in rolls of 108 sq.ft. costs $2.10 per roll in carload lots and $2.35 for smaller quantities.

Shingles, red and green slate finish cost $5.75 per square in carloads, $5.75 in smaller quantities, in Philadelphia.

ROOFING MATERIAL—Prices per ton f. o. b. New York and Chicago:

	Carload Lots N. Y.	Carload Lots Chicago	Less Than Carload Lots N. Y.	Less Than Carload Lots Chicago
Tar felt (14 lb. per square of 100 sq.ft.)	$64.00	$57.00	$65.00	$58.00
Tar pitch (in 400-lb. bbl.)	21.00	18.00	22.00	19.00
Asphalt pitch (in barrels)	36.00	36.00	41.50	41.50
Asphalt felt	67.50	67.50	72.00	72.00

HOLLOW TILE—Price per block in carload lots for hollow building tile:

	4x12x12	8x12x12	12x12x12
St. Paul	$0.056	$0.11	$0.162
Cincinnati	.086	.165	.218
Seattle	.09	.175	.30
Los Angeles*	.074	.144	.181
New Orleans	.16	.20	.29

*F. o. b. factory, 4, 8 and 10 inch.

LUMBER—Price of yellow pine per M in carload lots:

	1-in. Rough 10 In. x 16 Ft.	2-In. T. and G. 10 In. x 16 Ft.	8 x 8 In. x 20 Ft.
St. Louis	$38@41	$38.00	$40.00
Birmingham	33.00	33.00	28.50
Denver	43.00	35.00	43.00
Cincinnati	43.00	42.00	37.00

EXPLOSIVES—Price per pound of dynamite in small lots and price per 25-lb. keg for black powder:

	Low Freezing 20%	Gelatin 40%	Gelatin 60%	Gelatin 80%	Black Powder
New York		$0.29½	$0.34½		$2.40
Boston	$0.23¾	.26¼	.31¼	$0.35¾	2.65
Cincinnati	18¾	.22¼	.26¾		2.35
Kansas City	.20½	.25¾	.30¾	.38¾	2.45
New Orleans	.20¼	.26½	.31¾	.37½	2.60
Seattle		.25½	.32½

MISCELLANEOUS

GREASES—Prices are as follows in the following cities in cents per pound for barrel lots:

	Cincinnati	St. Louis,	Birmingham	Denver
Cup	7	7.2	8½	14½
Fiber or sponge	8	13	9½	18
Transmission	7	13	7½	20
Axle	4½	4¾	3½	5¼
Gear	4½	7½	5½	9
Car journal	22 (gal.)	4.9	6¼	8

BABBITT METAL—Warehouse prices in cents per pound:

	New York Current	New York One Year Ago	Cleveland Current	Cleveland One Year Ago	Chicago Current	Chicago One Year Ago
Best grade	87.00	70.00	80.00	93.00	75.00	70.00
Commercial	42.00	40.00	21.50	22.00	15.00	25.00

HOSE—Following are prices of various classes of hose:

Fire

	50-Ft. Lengths
Underwriters' 2½-in.	80c. per ft.
Common, 2½-in.	30%

Air

	First Grade	Second Grade	Third Grade
¾-in. per ft	$0.55	$0.40	$0.30

Steam—Discounts from list
First grade.....25% Second grade.....35% Third grade.....40%

LEATHER BELTING—Present discounts from list in cities named:

	Medium Grade	Heavy Grade
St. Louis	45%	50%
Denver	35–5%	30%
Birmingham	30%	35%
Chicago	45%	35%
Cincinnati	40–10%	30%

RAWHIDE LACING—50% for cut; 45c. per sq.ft. for ordinary.

PACKING—Prices per pound:

Rubber and duck for low-pressure steam	$0.90
Asbestos for high-pressure steam	1.60
Duck and rubber for piston packing	1.00
Flax, regular	1.20
Flax, waterproofed	1.60
Compressed asbestos sheet	1.00
Wire insertion asbestos sheet	1.20
Rubber sheet	.60
Rubber sheet, wire insertion	.80
Rubber sheet, duck insertion	.50
Rubber sheet, cloth insertion	.30
Asbestos packing, twisted or braided, and graphited, for valve stems and stuffing boxes	1.20
Asbestos wick, ½- and 1-lb. balls	.85

MANILA ROPE—For rope smaller than ⅝-in. the price is ½ to 2c. extra; while for quantities amounting to less than 600 ft. there is an extra charge of 1c. The number of feet per pound for the various sizes is as follows: ⅜-in., 8 ft.; ½-in., 6; ⅝-in., 4½; 1 in., 3½; 1⅛-in., 2 ft. 10 in.; 1¼-in., 2 ft. 4 in. Following is price per pound for ⅜-in. and larger, in 1200-ft. coils:

Boston	$0.24	Birmingham	$0.28
New York	.23	Denver	.22
Cincinnati	.24	Kansas City	.23½
Chicago	.21½	Seattle	.24
St. Paul	.23	St. Louis	.21½
San Francisco	.22	Los Angeles	.25

PIPE AND BOILER COVERING—Below are discounts and part of standard lists:

PIPE COVERING Pipe Size	Standard List Per Lin. Ft.
1-in.	$0.27
2-in.	.36
6-in.	.80
4-in.	.60
3-in.	.45
8-in.	1.10
10-in.	1.30

BLOCKS AND SHEETS Thickness	Price per Sq.Ft.
½-in.	$0.27
1 -in.	.30
1½-in.	.45
2 -in.	.60
2½-in.	.75
3 -in.	.90
3½-in.	1.05

85% magnesia high pressure ..... List

For low-pressure heating and return lines.....
4-ply..... 58% off
3-ply..... 60% off
2-ply..... 62% off

WIRING SUPPLIES—New York prices for tape and solder are as follows:

Friction tape, ½ lb. rolls	48c. per lb.
Rubber tape, ½-lb. rolls	60c. per lb.
Wire solder, 50-lb. spools	46c. per lb.
Soldering paste, 2-oz. cans	$1.20 per doz.

COPPER WIRE—Prices per 1000 ft. for rubber-covered wire in following cities:

No.	Denver Single Braid	Denver Double Braid	Denver Duplex	St. Louis Single Braid	St. Louis Double Braid	St. Louis Duplex	Birmingham Single Braid	Birmingham Double Braid	Birmingham Duplex
14	$15.00	$19.00	$38.40	$12.00	$16.00	$33.00	$12.50	$17.90	$36.30
10	22.65	29.05	58.25	27.20	31.00	69.00	30.30	34.30	67.60
8	31.95	39.20	78.65	38.00	42.00	78.00	42.35	46.85	
6	54.40	58.10			65.00	130.00	69.60	74.10	
4	77.50	83.00			93.00		101.75	106.55	
2	115.30	123.50			140.00		156.50	163.00	
1	150.05	161.20			182.00		201.00	209.50	
0		179.05			242.00		276.00	285.50	
00		243.35			290.00		317.00	330.00	
000		296.65			360.00		467.00	428.50	
0000		361.50			435.00		508.00	516.00	

FREIGHT RATES—On finished steel products in the Pittsburgh district including plates, structural shapes, merchant steel, bars, pipe fittings, plain and galvanized wire nails, rivets, spikes, bolts, flat sheets (except planished), chains, etc., the following freight rates per 100 lb. are effective:

Boston	$0.30	New Orleans	$0.38½
Buffalo	17	New York	.27
Chicago	27	Philadelphia	24½
Cincinnati	23	St. Louis	24
Cleveland	17	St. Paul	49½
Denver	99	Pacific Coast (all rail)	1.25*
Kansas City	59		

Note—Add 3% transportation tax. *Minimum carload, 80,000 lb.

COAL AGE

Volume 15 New York, February 20, 1919 *Number* 8

The Coal-Mining Outlook

By Floyd W. Parsons

CONSUMERS of domestic and steam coals entered the winter with bins and yards completely filled. As a consequence many coal companies today are practically without orders. The chief question is: How soon will the industry awaken from its present torpor?

The situation today is quite similar to that which existed in the coal trade directly after war was declared. Then we passed through a period of inactivity and doubt. Now we are again marking time while the Nation is gripped by an epidemic of national indecision.

When business finally struck its gait late in 1917, the demands for fuel came so suddenly that producers were unable to satisfy the needs. Serious shortages occurred. Are we moving forward to a time when history will repeat?

Bins and stockpiles are now being depleted of fuel. The coal that has been stored will be exhausted everywhere at about the same time. Perhaps also the railroads will have reached the purchasing point at this identical moment. Should this occur fuel supplies will be insufficient and prices will soar. Another fuel famine will be ushered in and Federal control will likely have to be reinstated.

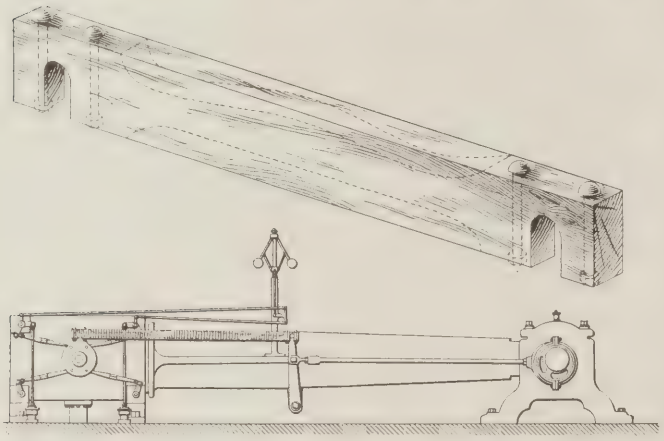
It is not wise for coal-mining men to look with complacency on present conditions. There is much to lose and nothing to gain by being damned by the public. To say "I told you so" is not sufficient. Consumers of coal have a short memory. Every possible effort must be made right now to point out the dangers that will arise from permitting coal stocks to be depleted.

The mild winter has caused a saving in coal consumption of about 5,000,000 tons. The slowing down in industries and the lessened demands on transportation are responsible for a further decrease in coal consumption of approximately 6,000,000 tons per month. The production of coal during January, compared with October, the last month of the war, showed a falling off of about 16,000,000 tons. The February decrease will be still greater. It is evident, therefore, that the falling off in output is considerably greater than the decrease in consumption. If this continues, a serious situation will arise.

Every effort should be made to get consumers to buy coal in moderation right now. If this is not done, prices are certain to go higher. The public has been misinformed. It has been told that if purchases were delayed, fuel prices would come down. Instead there has been an increase in the selling price of the higher-grade coals.

The hold-off policy of the railroads is further aggravating the situation. It is the next thing to criminal for politicians and transportation officials to set such an example at this critical time.

The sooner it is understood that coal cannot be produced unless there is a market for it, the better it will be for all concerned. Many consumers in various lines are beginning to realize what is coming and are crying aloud against the operators who have shut down their mines. These consumers forget that they do not go on manufacturing when their market disappears. And as for the newspaper editors who are demanding that coal be produced, let them consider: Do they print more papers than they can sell, and do they reduce the price of those left over?



Notwithstanding the present lull in business and the mild weather, more coal is being consumed than is being mined. This does not portend lower prices and a happy situation in the months to come.

IDEAS AND SUGGESTIONS

Ingenious Engine Repair Kept Mine Plant from Shutting Down

The coal-mine mechanic must be highly resourceful. He must keep the mine machinery going whether he has anything to keep it going with or not. If an engine or pump breaks down and no spare or repair parts are to be had, he must repair it anyway and keep it running. Otherwise the mine may be compelled to shut down, either in whole or in part.

The accompanying illustration shows an emergency

EMERGENCY REPAIR TO CORLISS ENGINE

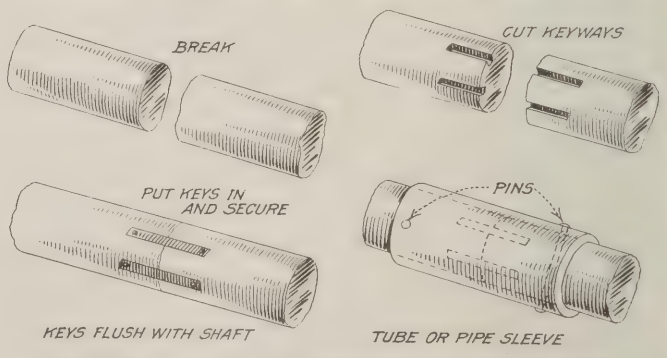
repair to a Corliss engine. The rod transmitting motion between the rocker arm and the wrist plate broke in such a way that it could not be readily repaired at the mine plant. The master mechanic was hurriedly called. In the course of a comparatively short time he had ascertained the exact distance between the rocker arm and wrist-plate pin centers, and the diameters of these pins. This distance center to center he laid out accurately on an oak plank of suitable dimensions.

About this time a carpenter that he had sent for arrived with a brace, an expansion bit, a square and a saw. First, holes of the diameter of the two pins were bored at the center points previously determined. The portion of the plank lying between these holes and one edge was then cut out, making a round-bottomed notch. The plank was then slipped over the pins on the valve gear and the engine started.

A new rod was of course immediately ordered. At the first opportunity the carpenter trimmed up the plank-valve rod substitute to the outline indicated by the dotted lines in the illustration. This rendered the plank much lighter, while leaving ample strength to work the wrist plate. Two small carriage bolts were also added at either end to prevent splitting.

This wooden rod, while it looked sufficiently ungainly to jar upon the nerves of any artistically inclined power plant man, kept the engine running and prevented a shutdown until the new rod arrived. It was then stored away carefully against a future emergency.

New Safety Detonator Does Away with Fulminate of Mercury



Although Germany has been in the throes of war for over four years, her chemists have been remarkably active and one of their new products is a safety detonator. This contains a cheap and effective substitute for fulminate of mercury. The latter, besides being costly, is dangerous to handle, and in the caps is unstable, a little dampness causing it to attack the copper or brass, forming a copper salt far more explosive than the fulminate itself.

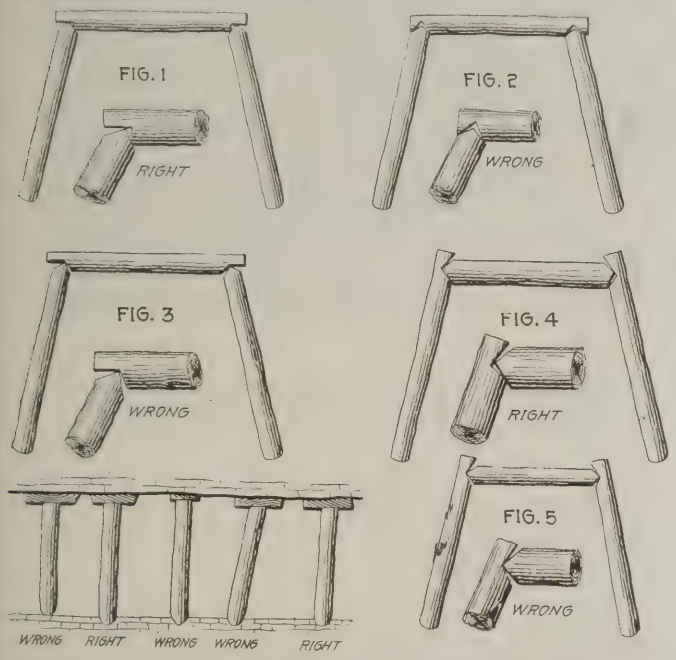
The new filling is a mixture of potassium chlorate and antimony sulphide—neither an explosive substance. Held against this by a thin strip of tin is a varnish of gum lacquer, containing ground red phosphorus and a little diphenylamine; and as the primer is detonated (through concussion) ignition is produced by friction of the phosphorus against the charge.

Temporary Repairs to Broken Blower Shaft Prevented Shutdown

BY CHARLES H. WILLEY
Concord, N. H.

Because of a flaw a 2-in. blower shaft broke, as shown below. The blower was urgently needed in order to carry the peak load, and it was therefore necessary to effect temporary repairs that would at least allow the machine to run at half speed until a new shaft could be obtained or the broken one fitted with a flange coupling

REPAIR DETAILS OF BROKEN BLOWER SHAFT



at the break. The way the difficulty was overcome is shown in the accompanying illustrations.

One drawing shows the shaft ends. Two keyways, $\frac{3}{8}$ in. deep and equally wide, were cut in each. Next the shafts were butted together and keys fitted and secured in place. Then a pipe sleeve was heated, slipped over the shaft and shrunk on over the break and the keys. This was also pinned in each piece of the shaft and the pins riveted over. The blower was run at three-fourths speed. Everything went nicely, and the job lasted until a new shaft arrived, which was about three weeks later.

Timbering in Mines Made Safe by Means of Drawings

By Joseph R. Thomas
Plymouth, Penn.

While there is no classification of employment in the mines where practical experience is more essential than in timbering, it has long been known that a large number of accidents have occurred owing to the improper methods with which mine timbers have been erected. A good scheme to adopt would be to have drawings made and posted on or near the mine entrance. These should show the right and wrong methods of setting timbers. There is no doubt that if this type of drawings was posted at the mines it would awaken the interest of the men, especially the younger ones. When it is borne in mind that the young man generally copies the methods adopted by the man with whom he works or has worked, and that having no other guide than to do his work the way the man he worked with did it, whether it was right or wrong, it is not surprising that the work continues to be done in an unsystematic, dangerous manner. If a sketch similar to the one here presented were posted at the mines I honestly believe it would prove beneficial to the whole mining industry.

FIGS. 1 TO 5. RIGHT AND WRONG METHODS OF TIMBERING

Hints to the Pulverized Coal User

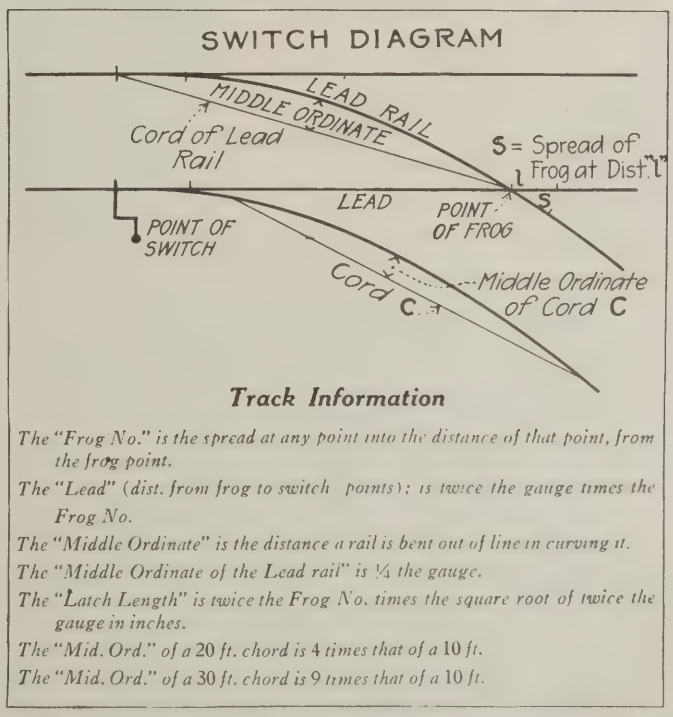
A. V. Adamson, discussing a paper read by H. R. Collins before the American Institute of Mining Engineers, makes the following interesting remarks:

1. Pulverized coal is not suitable for all purposes, and the character of the fuel available is one of the factors causing the necessity for separately considering each proposed installation.

2. Honeycomb and ash on tubes, and slag on walls and furnace floor, can be controlled.

3. Flame velocity must be reduced to a minimum.

4. No continuous operating efficiency or continuous good results can be obtained with pressure air for combustion, even if only ⅜ oz. pressure is used; and the more nearly a furnace approximates a balanced-draft condition, the better the operating results.



5. The incoming fuel must be mechanically mixed with the air-conveying medium to prevent a pulsating flame and the formation of coke due to lumps of pulverized coal in the feed.

6. Speaking generally, the use of coal in pulverized form, for steam generation, metallurgical and chemical work, affords fuel economy and increased production per unit. It is the one way by which the shortages of oil, gas, coal, transportation and labor can at one and the same time be met. Due consideration, however, must be given to the difficulties inherent in, and the troubles incident to, improper design and installation. In other words, an installation for the economic utilization of fuel in pulverized form is not one which can be purchased over the counter, and special experience or development is essential for each individual installation.

Common Track Difficulties and Their Solution

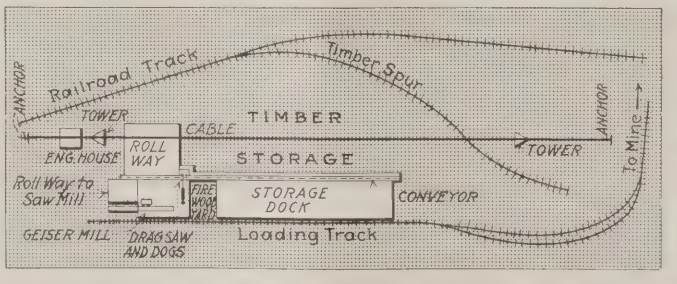
By Harry Goodnow
DuQuoin, Illinois

Many good articles and treatises on mine tracks and and their construction have been written and published, but unfortunately all foremen and track builders do not possess or have access to them. The data shown in the accompanying illustration may be printed on tracing cloth, blueprinted and furnished to every man in any way responsible for the construction or maintenance of tracks in the mine.

CARD GIVES VALUABLE TRACKLAYING DATA

Although the little "dope" card made up as described above can by no means be compared to some of the elaborate treatises on the subject of tracklaying, it nevertheless answers most of the questions that arise in the course of the day's work. It might well form therefore a part of each trackman's equipment.

Economical Timber-Handling Plant at an Anthracite Mine



By RALPH A. SMITH
Superintendent, Kingston Coal Co., Plymouth, Penn.

THE problem of supplying the Pennsylvania anthracite mines with the amount of timber necessary to safeguard both the men and the property has become more difficult year by year; the local supply of timber being about exhausted, it must now be obtained from a distance and is shipped into the collieries on railroad cars. Mining conditions in this region require the use of a much larger amount of timber per ton of coal mined than the average bituminous mine of the country, a mine of moderate tonnage often consuming over 250,000 lineal feet of such timber in one year. Timber is often delivered in car lengths and of a diameter at times as large as 36 in., making it an expensive task to unload and prepare it for use by hand.

The Kingston Coal Co., at its mines in Edwardsville and Plymouth, Penn., has installed a modern system by which this is done with a minimum amount of hand labor. The accompanying plan shows the general layout of the scheme. A cable haulage transfer system delivers the logs from the railroad car to either the rollway or to the stock pile. A 9 x 12-in. Lambert double-drum transfer hoist, 1½-in. steel wire cable, and $\frac{9}{16}$-in. steel wire transfer and hoist ropes, make up this part of the outfit.

The towers are of wood, about 30 ft. high, with a span between them of 300 ft., giving ample storage room for stock timber. Logs placed on the rollway are delivered into an electric-driven conveyor of 6-in. pitch Keystone chain, with 3 x 5-in. hardwood carrying blocks. The conveyor is driven by a General Electric 30-hp., 250-volt, direct-current motor, with a Type A controller, manufactured by the Electric Controller and Supply Co., Cleveland, Ohio, and can be operated in either direction. The sides of this conveyor are marked in feet in both directions from the saw, so that props can be cut to length without the necessity of resorting to a tape or rule.

A No. 0 steam drag saw and a pair of steam dogs, manufactured by the Hill-Curtis Co., Kalamazoo, Mich., are so located that the props are cut without removal from the conveyor. It requires an average of 30 seconds to cut through a 24-in. hardwood log. From the saw, the cut timber still travels in the conveyor along the distributing dock, where it is stored by sizes and from which it is loaded for transportation into the mines. All these operations are accomplished with a minimum amount of hand labor. Waste ends, and also the broken timber removed from the mines, are made into firewood by a special cutoff saw and wood splitter, the wood being sold to employees at the actual cost of handling. A Geiser saw mill is connected with the plant and selected logs are turned into such sizes of lumber as are needed to serve different purposes at the colliery and shops.

Bradford Coal Breaker and Preliminary Mechanical Cleaner

SYNOPSIS—*In coal preparation where a large percentage of screenings or slack is desired, the Bradford breaker or screen finds a legitimate field of activity. This device for breaking coal into small pieces and cleaning it of impurities is used principally in connection with coke plants and to a less extent in preparing bituminous coal for producer, stoker or special use. Its construction, operation and advantages are here noted; some interesting tests of what has been accomplished by this device at commercial plants are given.*

AT THE present time it is a common practice in some coal-mining sections to use a Bradford coal breaker as the first unit for the preparation of bituminous coal to be coked, or the sizing of run-of-mine coal for producer or stoker use. The principal function of the apparatus is to break and screen mined coal to a size suitable for further reduction by crushing, or for producer or stoker use, simultaneously discharging in a separate chute a portion of the material tougher than the pure coal. The breaker was patented in 1873 by Hezekiah Bradford, of Reading, Penn. He had in view the breaking, sizing and preliminary cleaning of anthracite coal, without causing the excessive quantity of fines produced by the toothed rolls then in general use. However, it did not accomplish, on a commercial scale, what was proposed on account of the nature of anthracite coal and intermixed impurities. Its first employment in the preparation of coking coal is recorded in 1891, when the St. Bernard Coal and Coke Co. (Earlington, Ky.), the St. Clair Coal and Coke Co. (Bradenville, Penn.) and the Loyalhanna Coal and Coke Co. (Loyalhanna, Penn.) used it for the breaking, sizing and preliminary cleaning of coal.

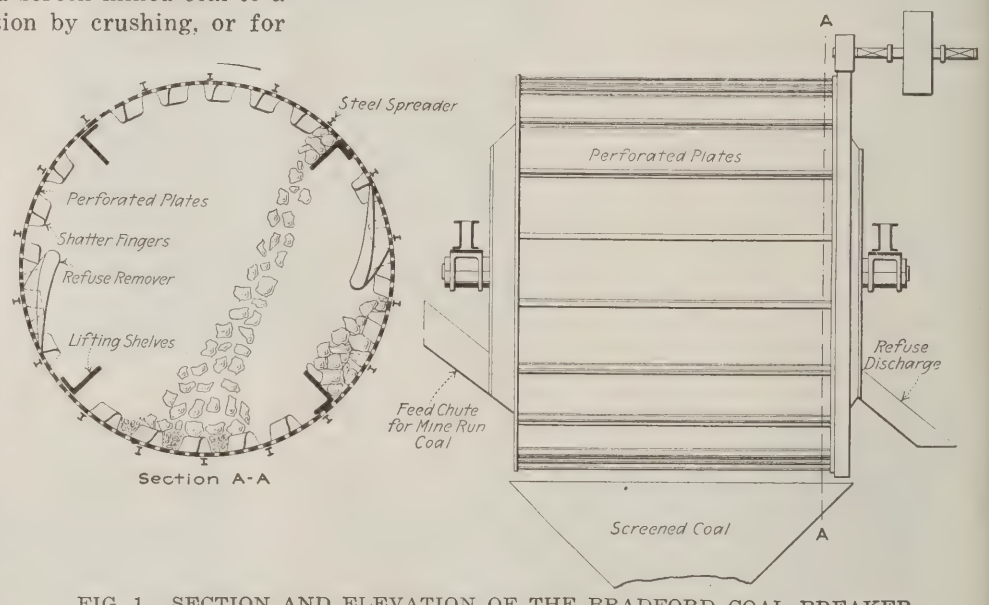

FIG. 1. SECTION AND ELEVATION OF THE BRADFORD COAL BREAKER

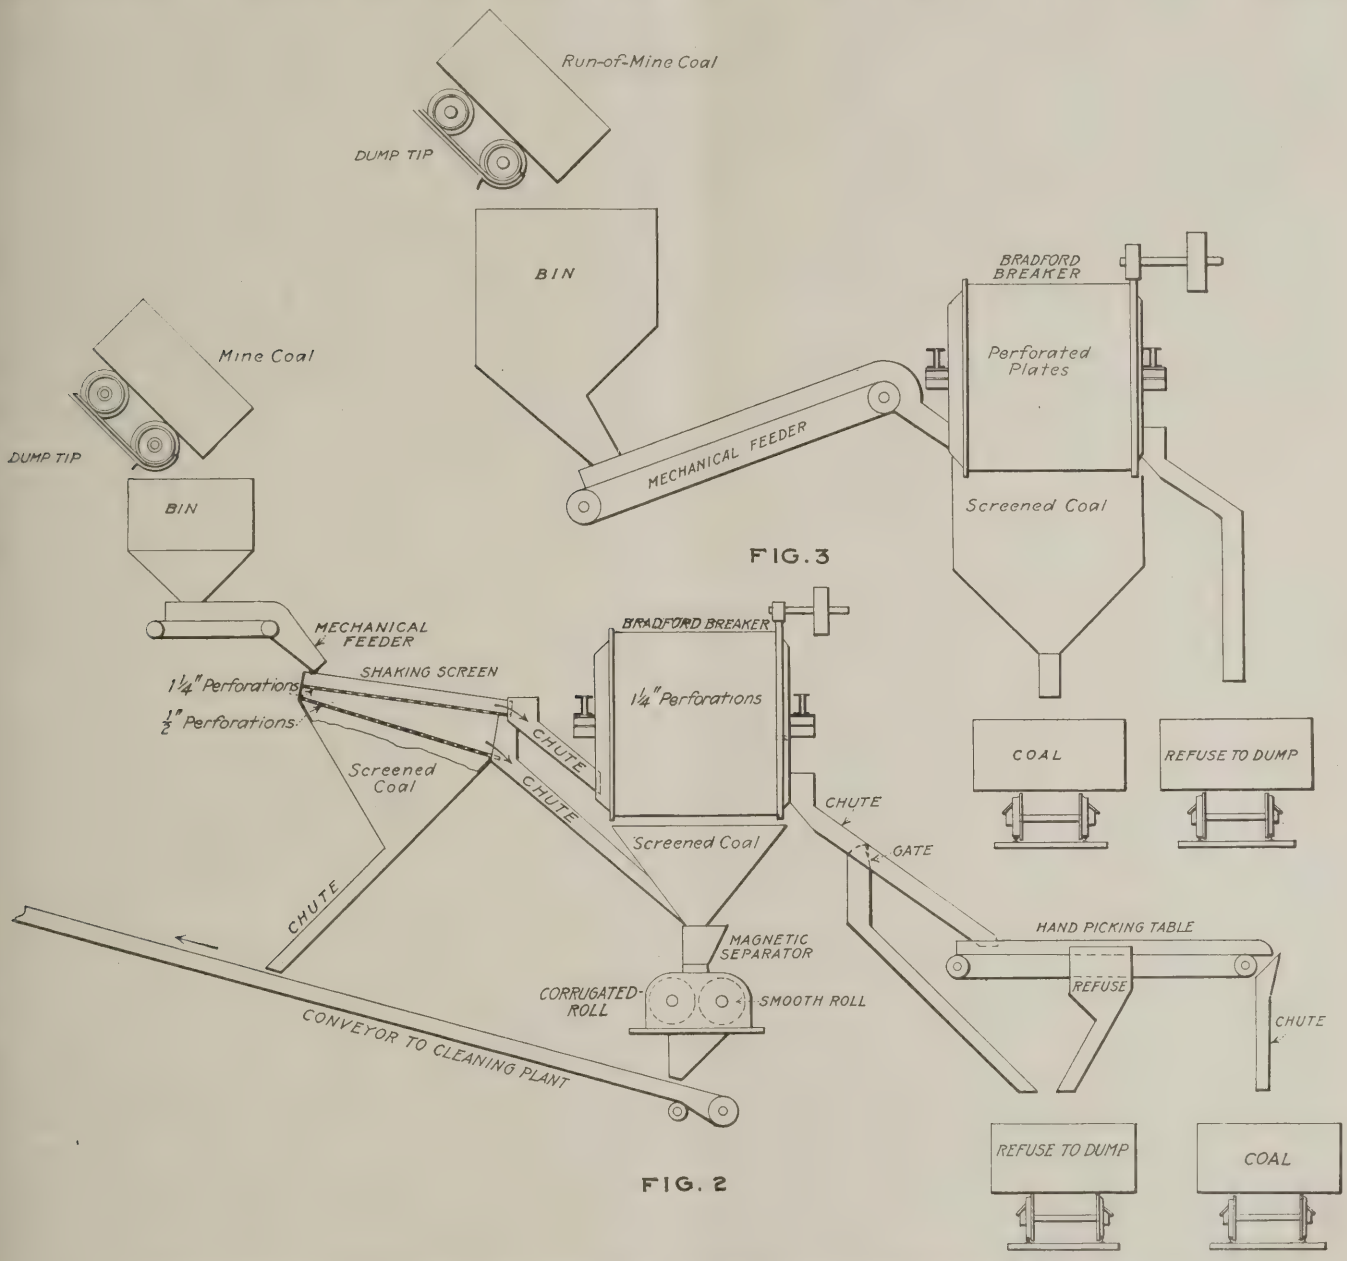
At this time there are approximately 300 Bradford breakers in active operation in the United States; about 75 per cent. of these are in connection with byproduct and beehive coke-oven plants, the others for preparing bituminous coal for producer, stoker and special use.



The present construction and operation of the breaker differ materially from the first installation and early practice, the improvements being important and of value; while the original machine demonstrated the merit of the principles involved, yet its mechanical operation or action was not satisfactory. The principle is to break the pure coal by concussion and screen it out through the encircling perforated plates, while the impurities, mingling with the mined coal, are generally too tough to be broken by this force of concussion and therefore pass over the perforations and out at the end of the machine to a separate chute. The breaker consists of a large diameter cylinder covered with perforated steel plates; it is intended to revolve slowly.

The machine is useful for preparing coal for further crushing and cleaning (Fig. 2); however, if the coal, after passing through the perforations of the breaker, is considered clean enough for coking, then a pulverizing mill is substituted for the rolls, so that impurities intermixed with the coal will be powdered and the whole product be of the same degree of fineness. The function of the Bradford screen is to break the pure coal to a size that will sift through the perforations, without breaking much of the bony coal, slate, rock and pyrites intermixed with the coal; further, that these impurities may be discharged separately. It also automatically discards foreign matter larger than the perforations, like car and rail irons, wooden sprags, and so on, that would be injurious later to the rolls or pulverizers. Bins are provided which act as reservoirs to insure a uniform supply of coal to the preparation plant and as storage in case of irregular delivery of coal from the mines.

The mechanical feeder not only regulates the tonnage delivered to the screens but also tends to balance the loading of elevators and conveyors handling the prepared coal. The shaking screen separates the coal into sizes suitable for further treatment; it relieves the breaker of handling coal already of the proper size for the rolls, and it also bypasses around the rolls the coal that is fine enough for use. The duty of the magnetic separator is to remove pieces of iron, like bolts, nuts, rivets and mining machine parts, that drop through the

perforations, thus preventing serious injury to the rolls or the pulverizer.

The advantages of rolls are that they break the coal so as to release more or less of the impurities of a laminated nature, without pulverization; crushing, grinding, pounding, bruising and pulverizing all tend to create powder or dust of both the coal and the impurities; this latter is quite an unfavorable condition and plants when the coal seam is quite free from impurities. Table I is a record of Bradford coal-breaker tests made at coal plants. Complete details are noted. All these tests, with the exception of Nos. 6 and 11, are taken from monthly averages, and at coal plants operating in connection with byproduct coke ovens. No material reduction in ash or sulphur content is shown with the exception of tests Nos. 5 and 11. No. 5 indicates

FIGS. 2 AND 3. TWO TYPICAL INSTALLATIONS OF BRADFORD BREAKER AND ACCESSORIES

hinders success in either a dry or wet method of coal preparation.

The hand picking table is of use when the coal seam contains bands of bony or high ash coal; the breaker is then adjusted and operated to discard as much as possible of this inferior coal, together with the other bulky impurities, as these coals inferior for coking purposes contain much fuel value for steam and domestic use; the fuel values are separated from real impurities by hand, while being conveyed on the picking table.

Fig. 3 illustrates the average installation of a breaker for preparing stoker coal or for other special use; this arrangement is also used at some beehive oven coke

an ash reduction from 13.10 per cent. to 11.15 per cent., and sulphur reduction from 3.35 per cent. to 2.90 per cent., by screening out 3 per cent. of the impurities. No 11 test indicates an ash reduction from 16.88 per cent. to 13 per cent., and sulphur reduction only from 0.86 per cent. to 0.84 per cent., by taking out 14 per cent. of the impurities. Both the run-of-mine and screened coal from this test (No 11) were not satisfactory, regarding the ash content, for coking. The screened coal, after the 14 per cent. of impurities was removed by the breaker, was washed, with the results shown in the record of No. 11 test. While the ash content was further reduced to 9.13 per cent. in the washed

coal, there was discarded as refuse a total of 26.52 per cent. of the run-of-mine coal—14 per cent. with ash, averaging 41.21 per cent. by the breaker and 12.52 per cent. with ash or 35.71 per cent. by the washer; of course, the great loss of the original run-of-mine coal to reduce the ash content in the coal to a point practical for coking use would not permit the installation of a commercial cleaning plant.

In the general operation of the Bradford breaker run-of-mine coal is automatically fed into one end of the cylinder (while revolving), is picked up by longitudinal shelves and dropped, falling on cast steel "shatter fingers" attached to the perforated plates; the coal is shattered by concussion (See Fig. 1), and the pieces that are small enough sift through the perforations; the shelves following pick up the large pieces, which are again thrown down. The coal in falling from the shelf has not only the force derived from its own gravity, but receives considerable additional force from the momentum of the cylinder. The coal does not fall upon coal in the lower part of the cylinder, but upon the shatter fingers and perforated plates, because the coal is constantly carried toward and upon the rising side and

in the making of which certain ingredients are used under fixed conditions with results always approximately the same; on the other hand, it is a natural product varying greatly in quality, often even in the same seam, and it must be admitted that any attempt to standardize a coal-preparing machine or method under these circumstances would prove an almost impossible task. Coal always contains a certain amount of inorganic matter or ash, which is intrinsically part of the coal. The question as to whether one could clean a given coal materially or not depends largely—essentially, in fact—on the way in which that inorganic matter was distributed through the coal.

The rated capacity of a breaker is the number of tons that can be broken enough to sift through certain size perforations in a given time (usually one hour), and simultaneously to discharge separately from the broken coal the impurities not broken by the action of the breaker. Breakers, now in operation, vary in capacity from 30 tons an hour—fitted with ½-in. perforations and handling tough coal—to 400 tons an hour—fitted with 3-in. perforations and handling friable coal.

The quality of work done by a breaker is shown by

shelf. In rolling and tumbling around in the cylinder any remaining pieces of pure coal attached to the impurities break away and sift through the perforations. The cast-steel shatter fingers not only aid in shattering the coal, but are so set on the inside of the cylinder as to form a spiral, which can be adjusted either to rapidly advance the body of coal to the opposite end or to retard its progress. Fastened in the opposite head of the cylinder from which the coal enters are refuse removers (wing-like in form) which automatically discard any impurities or other matter larger than the perforations into a chute. The coal sifting through the perforations on the revolving screen is collected underneath the cylinder and is conducted by a chute to the desired point for shipment or treatment.

The Bradford breaker is adjusted and detail parts are designed to suit the physical characteristics of the coal to be treated, the requirements of the market and the general conditions and circumstances of each individual case. The capacity and quality of work is affected by the diameter and length of the screen, the size of perforations, speed of rotation, spirality of the shatter fingers and the moisture content and physical properties of the pure coal and impurities. The difficulty with coal, of course, is that it is not a manufactured article, the quantity of pure coal broken fine enough to sift through its perforations, without at the same time breaking the impurities (that are more or less intermixed with the coal) so small as to permit of their passing through the perforations; thus these impurities may be discharged separately from the coal. When making comparisons of different installations regarding the capacity and quality of work done by breakers, it must be kept in mind that many coals which break cubical in shape (or nearly so) go through a screen quite fast, but coals which break in elongated pieces do not screen nearly as fast as the cubical coal. Also, when comparing laboratory tests with commercial results, it should be remembered that the laboratory tests show the best theoretical results attainable by working in the ways described—the laboratory results represent the ideal to be attained by commercial methods.

Structurally a Bradford breaker is a circular screen of perforated plates which are bolted to an iron framework; cast-iron spiders, or rings, carry this framework, and these rings are rigidly connected to a central longitudinal revolving shaft. The screen is inclosed by a casing which confines dust and prevents its circulation throughout the tipple; the casing protects workmen against accident and yet suitable doors are provided so

that necessary inspection of the screen and its operation can be made. All portions of the screen are constructed so as to permit of ready renewal or adjustment of parts; should the character of the coal being prepared change, or different marked conditions develop, then parts either can be replaced or adjusted without serious disturbance to the plant. The perforated screen plates are made of extra heavy steel cut to a standard size so as to fit any breaker of the same diameter. These plates can have one size perforations at one end of the screen and larger perforations at the other end; this arrangement permits of two sizes of coal being made. Suitable provision in the chute to carry off the screened coal keeps the two sizes separate.

The cast-iron lifting shelves in the screen are made of a width, length and angle proportioned to the work desired and the speed of rotation, so that the coal may slide from the shelves at the proper height to fall upon the required part of the inner side of the screen; the shelves are made interchangeable and can be replaced or their position changed without affecting other parts of the breaker. Usually four shelves are equally spaced on the inner side of the screen, although from one to six shelves may be used, depending on the coal handled.

The cast-iron refuse removers in the screen automatically discharge the impurities; generally two are used for rapid discharge. However, if a portion of the coal is more or less tough, so that it requires further tumbling to break up the coal, then only one remover is used. In selecting a breaker it will be well to confer with those familiar with the principles involved, its construction and operation; also, one should be thoroughly versed as to the nature of the coal to be handled and the separation of impurities desired. Each variety of coal requires special treatment in the breaker, which can only be accomplished by properly proportioning the parts during construction. The method of operation should be determined after a careful study of the physical properties of the coal. A knowledge of the business end of the proposition is essential, as that often makes all the difference between success and failure. It is rather remarkable that in some districts collieries which are in close proximity to each other sometimes differ in a radical manner in their treatment of the same seam of coal. In designing a plant it is not always safe to rely on a neighbor's experience, or even on one's own experience elsewhere. This uncertainty is often most puzzling and perplexing, but perhaps it is the most interesting of the various problems in connection with mining engineering.

Details of No. 11 Test—Below is given a record of five tests made with run-of-mine coking coal from five mines working the same coal seam with a Bradford coal breaker 9 ft. in diameter and 11 ft. long. Perforations ½-in. square, peripheral speed 425 ft. per min. Feed 60 net tons per hour. The coal was quite soft and dry, the rock and bony tough and the slate brittle.

RECORD OF TESTS WITH RUN-OF-MINE COKING COAL

	Run-of-Mine Coal		Screened Coal		Breaker Refuse	
Mine	Per Cent.	Per Cent. Ash	Per Cent	Per Cent. Ash in Screened Coal	Per Cent.	Per Cent. Ash in Refuse
1	100	18.70	87.71	14.10	12.29	51.30
2	100	15.45	86.43	10.84	13.57	44.65
3	100	16.25	85.81	13.00	14.19	35.70
4	100	15.80	90.17	13.30	9.83	38.40
5	100	18.22	79.85	13.72	20.15	36.00
Average,	100	16.88	86.00	13.00	14.00	41.21

The foregoing tests show that discarding 14 per cent. of the impurities in the run-of-mine coal larger than the ½-in. perforations reduced the ash content from 16.88 per cent. to 13 per cent., which was not acceptable for furnace coke. The screened coal from the five tests was washed, with the results shown below:

Kind	Per Cent. Run-of-Mine Coal	Per Cent. of Kind	Per Cent. Ash
Breaker screened coal	86.00	100.00	13.00
Washed coal	73.48	85.44	9.13
Washer refuse	12.52	14.56	35.71

The foregoing results indicate that to reduce the ash content from 16.88 per cent. in the run-of-mine coal to 9.13 per cent. in the washed coal it was necessary to discard a total of 26.52 per cent. of the run-of-mine coal as breaker and washer refuse.

Deep-Seam Working Opens Up Question of Reducing Temperature

By Mark Meredith
Liverpool, England

The time has arrived when it is believed means should be taken to deal with the detrimental effects of continuous working under conditions of high temperature in certain mines. At the Ashton Moss colliery (the deepest in Great Britain) and others, many improvements which have been made during the last 30 years would be as essential in working beds of coal at 4000 ft. as they have been within recent years in mines of one-third that depth.

Among these improvements might be mentioned a safety lamp capable of withstanding an explosive current traveling at a high velocity, the introduction of electric light, the modern fan and the mechanical under cutting of the bed (in longwall working) in straight lines. There will be a greater percentage of small coal in deeper mines, due to the crushing effect of the overlying weight, but modern experience has shown that small coal, which formerly commanded a low price, has now become a valuable asset through the development of byproduct plants. In recent years explosions have been less frequent than formerly, and it may be expected that freedom from serious accidents will continue.

In order to effect a reduction of the temperature in the deeper mines, and render them as suitable for human effort as those in beds of less depth, some modifications will be required in the systems hitherto adopted for conveying the intake air along certain roadways to the coal face and returning the vitiated air along other roads to the upcast shaft.

Information is now sought from the makers of modern refrigerating plants concerning their experience in cooling atmospheres, so that colliery officials may consider how similar systems may be utilized for reducing the temperature in deep workings.

The use of compressed air in place of steam is one means of keeping the temperature down, as is also the driving of roads for cold-storage chambers in suitable strata within a reasonable distance above the coal beds to be worked, in which large volumes of air from the downcast shaft could be cooled and dried by means of refrigerators, to a temperature suitable for men to work in.

A Study of Shoveling as Applied to Mining—II*

By G. TOWNSEND HARLEY
Tyrone, New Mexico

SYNOPSIS—*Where the material mined must be moved over a certain distance it is advisable to employ a car. For best results this should be placed about 4 ft. from the pile to be moved. The shape of shovel used and its length of handle have a decided effect on the amount of shoveling done. The system of payment for work performed has a strong influence upon the success of any scheme for increasing the individual efficiency of miners or mine laborers.*

IN FIG. 28 is shown the number of shovels per minute thrown into a car for any length of job. In this series of tests the ore was thrown a horizontal distance of 4 ft. into a mine car 42 in. high; 4 ft. seems to be the best distance to maintain between car and ore pile, for a man to work to the best advantage. Due to the height of the car, the capacity of a shoveler is decreased, as compared to his capacity in shovels per minute, when loading into a wheelbarrow. This decrease in shoveling speed amounts to about 8 per cent. per foot of height. The best type of car for a shoveler to use holds about a ton of ore, is as low as is consistent with good design, certainly not over 45 in. in height, and is equipped with roller bearings, which should be kept in the best of condition. Cars much larger than this are too hard to tram and cars much smaller use up too much of the shovelers' time tramming back and forth.

Fig. 29 shows the effect of having to throw the ore a greater distance than 4 ft. into the car, for a given length of job, using a No. 4 D-handle shovel. For every additional foot between the car and the ore pile, the height of the car remaining constant, the decrease in shoveling speed amounts to about 3.6 per cent.

In Fig. 30, Chart A shows the time consumed in tramming, dumping, and returning with the car, over various distances. Chart B shows the average tramming speed that will be developed for any distance over which the ore has to be conveyed.

Fig. 31*A* shows the amount of rest required for various lengths of jobs under constant conditions of length of tram, and distance and height through which the ore is thrown by the shoveler. For any length of job, as the length of tram increases, the amount of rest needed is increased, as shown in Chart B. Both of these lines, however, are quite flat, for a man can get nearly enough rest as he returns each time with the empty car.

Fig. 32 shows the tonnage to be expected of a man mucking into a car and tramming a constant distance, for various lengths of jobs. It will be noticed that the economic shoveling day is between 7 and 8 hours and that the maximum average results to be expected of a mine shoveler under the given conditions have probably been reached.

Fig. 33 is made up for a uniform shoveling day of 6 hours and 12 minutes and shows the tonnage to be expected under average shoveling conditions for any distance that the ore must be thrown or trammed. The line representing the tonnage to be expected of a man with a wheelbarrow may not be entirely correct, especially as the length of tram increases. It is thought that up to 15 ft. the line is about correct but that it may slope off a little too rapidly beyond this point. On the other hand, the wheelbarrow is generally used where neither direct shoveling nor the use of a car, with its attendant track expense, etc., is feasible; consequently, the wheelbarrow is always at work under adverse conditions in a stope and no improvements over the results here tabulated are to be expected. The writer thinks that the work with a wheelbarrow in a stope has been closely approximated but that a greater efficiency could be obtained in a clear and unobstructed passage, such as a drift. The calculation of the tonnage expected when tramming either with a car or

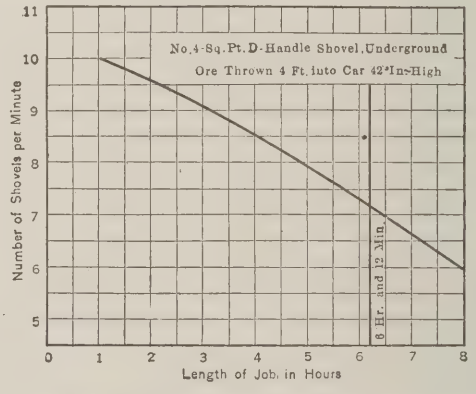

FIG. 28. EFFECT OF LENGTH OF JOB ON NUMBER OF SHOVELS PER MINUTE

wheelbarrow, for any length of job and distance trammed, is expressed in the following formulas:

Let W = Weight of load on shovel, in pounds;
N = Number of shovels per minute, Figs 24 and 28;
P = Per cent. of time actually shoveling, Figs. 26 and 31;
L = Length of job, in minutes;
T = Total tonnage shoveled;
a = Time to load one car or wheelbarrow;
b = Time to tram and dump one car or wheelbarrow, in minutes, Figs. 25 and 30;
c = Load on one car or wheelbarrow, in pounds.

*Concluding installment of a paper presented before the February meeting of the American Institute of Mining Engineers. The first part of this article appeared in *Coal Age*, Feb. 13, 1919.

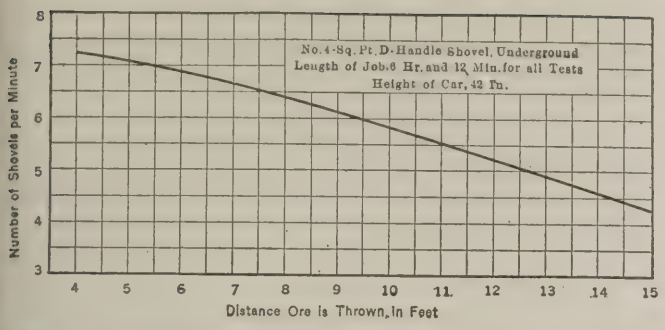

FIG. 29. EFFECT OF DISTANCE THROWN ON NUMBER OF SHOVELS PER MINUTE

Then

$$\frac{c}{W \times N} = a \qquad \frac{\left(\frac{L}{a+b}\right) \times c \times P}{2000} = T$$

Example 1.—What will be the total tonnage handled, using a 21-lb. shovel and a wheelbarrow, and tramming the ore 20 ft. for a job of 5 hours duration?

It is necessary first to find the time required to load one wheelbarrow, or

$$a = \frac{315}{21 \times 9.3} = 1.61$$

then the total tonnage handled is

$$T = \frac{\left(\frac{300}{1.61 + 0.56}\right) \times 315 \times 0.88}{2000} = 19.5$$

Example 2.—What tonnage will be handled in 6 hours and 12 minutes, using a car of 1-ton capacity and a shovel of 21-lb. capacity, tramming a distance of 100 ft.? As the time required to load one car is $\frac{2000}{21 \times 7.2} = 13.3$; the total tonnage handled is

$$T = \frac{\left(\frac{372}{13.3 + 2.43}\right) \times 2000 \times 0.73}{2000} = 17.23$$

To determine the relative wearing qualities and the cost per ton for supplying the men underground with new shovels, different places in the mines were equipped with different makes and styles of shovels and the results carefully noted. At frequent intervals, these shovels were measured to detect the wear of the blade, and checked up to see that all were being used in the proper places underground; the tonnage coming from each place and the number of shovelers employed were also noted. Table III gives the results obtained with the different classes of shovels.

The shovels made of chrome-nickel and special steel were excellent implements but the special steel shovel was considerably heavier than the other. Cracks developed along the form line of the chrome-nickel steel blade, on each side, but these did not impair the shovel's usefulness. The blades of the three other shovels bent easily with rough usage; while the blade made of extra light carbon steel wore very rapidly and the edges curled up almost immediately. The No. 2 scoop was used until its capacity had been reduced 25 per cent. and the No. 4 shovel, until its capacity had been reduced 9 per cent. The cost of shovel per ton handled includes the cost of the shovel, freight, supply-house handling, handling new shovels into mine, and disposal of worn shovels. We had hoped to be able to detect a difference in the man efficiency on account of the different styles and weights of shovels in use at this time, but owing to the constantly changing conditions in the working places selected for the trials, no conclusive evidence was available.

The wearing quality of any shovel used on an iron sheet varies from 74 per cent. to 86 per cent. of the wearing quality of the same shovel on a wooden mat, the average being 82 per cent. The wearing quality of a shovel on a rough bottom is about 90 per cent. of that on a wood mat. These figures are based on about 50 observed shovels underground.

TABLE III. SCHEDULE OF WEAR OF SHOVELS

Type of Shovel	Used on	—Tonnage Handled by Blades Made of— Chrome-nickel Steel	Secret Composition Steel	Common Carbon Steel	Extra Light Carbon Steel
No. 2 scoop	Iron sheet	1220	950	750	.....
No. 2 scoop	Rough bottom	.....	.....	.....	.....
No. 2 scoop	Wooden mat	1500	1100	900	.....
No. 4 shovel	Iron sheet	990	770	620	250
No. 4 shovel	Rough bottom	1075	870	.....	.....
No. 4 shovel	Wooden mat	1168	1000	730	340
Gage of steel in blade		15	13	14	16
Cost of shovel per ton handled, cent.		0.0015	0.0018	0.0019	0.0026

Tests were conducted with square- and round-point shovels varying in size from No. 2 to No. 6 and with standard No. 2 scoops, to determine what size of shovel was best adapted to the work. For short jobs of less than 4 hours' duration, the No. 2 scoop and the Nos. 5 and 6 shovel were slightly the best from the standpoint of tonnage handled; but for jobs requiring more than four hours for their completion, the No. 4 shovel was greatly superior, see Fig. 22. From the standpoint

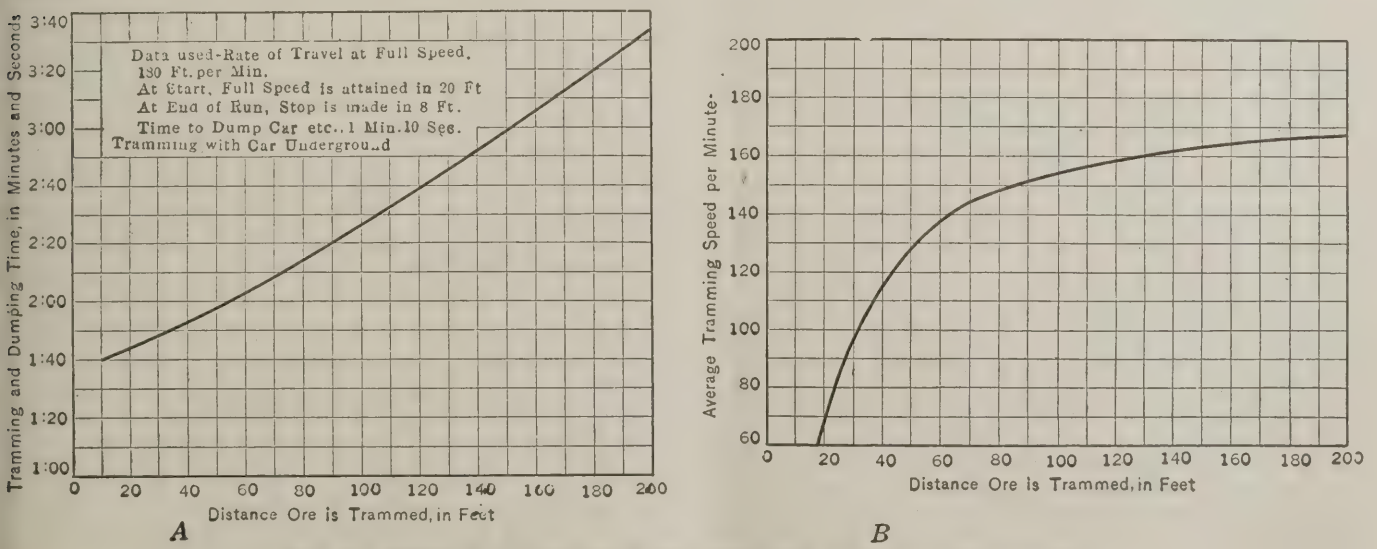

FIG. 30. EFFECT OF DISTANCE ON TIME AND SPEED OF TRAMMING

of "number of shovels per minute," work with a scoop is at all times slower than with a No. 4 shovel, see Fig. 18, and as the day progresses the percentage of time required for resting becomes greater with the scoop than with the shovel, see Fig. 20. The result is that although for short work periods, the larger capacity of the scoop brings the total tonnage handled above that of a No. 4 shovel, for long periods the increased amount of rest required when handling the heavier load serves to put the No. 4 shovel considerably in the lead as a tonnage mover. With shovels smaller than the No. 4, the number of shovels per minute was not increased, and the amount of rest required was not decreased enough to make the smaller shovel superior for any working period. It may be stated as a generalization, that for shovels smaller than the 21-lb.-load shovel, the tonnage handled per shift is approximately directly proportional to the shovel capacity; that is, if a man using a No. 4 shovel will handle 26 tons in an 8-hour shift, with a No. 3 shovel which holds 91 per cent. of the load of a No. 4 shovel, he would be expected to move about 24 tons a shift. If the increased cost of shoveling with a smaller shovel, or one that has been worn, is balanced against the cost per ton of putting a new shovel underground and discarding the old one, it will indicate the economic limit of wear of the shovels in use. We have, for the present, rather arbitrarily selected as the limit a shovel of size No. 4, which has been worn to about 12 in. in length, or roughly a 9 per cent. to 10 per cent. reduction of capacity. The lift of a shovel is important. By "lift" is meant the amount of rise in the handle just behind the blade. A handle that has not much bend in it at this point, but which goes off straight is said to have a low lift, while one that arches steeply is said to possess a high lift. To work with a shovel having a low lift the man must stoop down farther each time to take a grip on his shovel after it has penetrated the mass, and the added movement takes longer, and requires a greater effort to lift the weight of the body and the load through a greater space than with a high-lift shovel. As a result, more rest is required in the course of a day. With a very low lift, the shovel is not well balanced and there is a tendency for it to turn over in the hand, especially if it is not loaded evenly. With a high lift, the man does not have to stoop so far to grasp his shovel, the amount of rest period is decreased, and the loaded shovel is better balanced, because its center of gravity is well below the line of the handle. A lift of 8 in. is the best, as with greater lifts the awkwardness of the throwing movement is considerably enhanced. The height of the end of the handle above the floor when the shovel blade is flat on the floor is of considerable importance, too; this is the measurement that the manufacturers call the "lift." In a short-handle shovel, the end of the handle should strike just above a man's knee, a height of 23 in., to give the most effective effort in penetrating the mass. With a long-handle shovel the height should be the same at a distance back of the blade corresponding to the length of the short handle.

It is an advantage to have the weight of the shovel as low as is consistent with good material and length of life. Increasing the weight of the shovel slows up every motion involved in shoveling and increases the amount of resting required. However, it is not wise to go to extremes in the matter, as a very light shovel does not possess the strength and wearing qualities, and the cost of constant replacement is greater than the advantage gained in shoveling speed. In a personal communication, Frank B. Gilbreth says: "The 21-lb. load refers to shoveling any kind of material anywhere, above ground or below ground, and this is the live load upon the shovel and does not include the weight of the shovel. I make this statement after having asked this question of Mr. Taylor. Obviously it would have been better if the data had been obtained on the basis of having the load, live and dead, combined in one figure."

As we lacked information, we assumed that Mr. Taylor experimented, at least in part, with stock shovels, which weigh about 6 lb. in the No. 4 size. Our experiments were conducted with shovels of both regular and special design, varying in weight from 4 lb. and 10 oz. to 6 lb. and 5 oz., and we found that a shovel weighing between 5 lb. and 8 oz. and 5 lb. and 10 oz. gives the greatest per man capacity. This is a total combined live and dead weight of 26 lb. and 8 oz. to 26 lb. and 10 oz. A shovel of this weight can be made quite sturdy, the gage of blade being No. 15 of some composition steel and the handles of best selected XX second-growth northern white ash. With heavier shovels, there is a distinct falling off in capacity; while for lighter shovels, although we could detect no difference in capacity, the wearing quality was poorer, due to lack of strength.

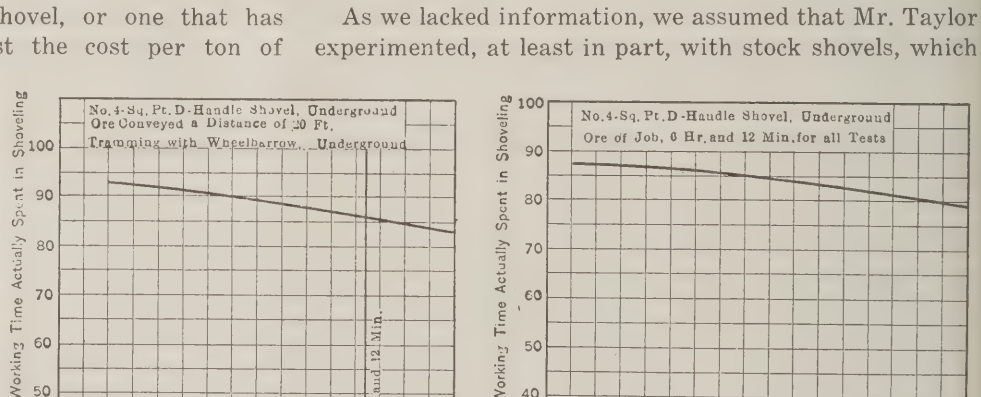

FIG. 31. REST PERIOD REQUIRED FOR VARIOUS CONDITIONS OF WORK

The use of the scoop is not advocated except where the material to be moved is so light that the scoop holds only 21 lb. Even for short jobs its use offers only a doubtful advantage, see Fig. 22. For shoveling on any sort of a mat or platform, the square-point shovel is the better; while for scraping down and working on a rough bottom, the round-point shovel should be used. Where there is plenty of room for men to work, the long-handle shovel of both square- and round-point pattern is superior to the short-handle. This is

true for all distances and heights to which the ore has to be thrown, and the farther or the higher the ore has to be thrown, the more pronounced is the superiority of the long-handle type.

D. J. Hauer says that where men are working in a free space they can do, on an average, 10 per cent. more work with a long-handle shovel than with the short-handle; that the limit of throw, taking only one step, is 12 ft. with a long-handle shovel and 9 to 10 ft. with a short-handle shovel. We have checked Hauer on these points and find his statements on the relative efficiency of the two types of shovels to be substantially correct; but we found that it is economy to throw as far as 12 ft. with a short-handle shovel and 14 ft. with a long-handle. Unfortunately, however, most working places underground are restricted in area and it is necessary to use the short-handle shovel. Where one man is shoveling in a drift, or one to each set of timber in a stope, the long-handle shovel can be used to advantage. Where men are working $2\frac{1}{2}$ to 3 ft. apart, a short-handle shovel should be used. According to D. W. Brunton and J. A. Davis, in U. S. Bureau of Mines' *Bulletin* No. 57, the minimum spacing of men working side by side in a drift should be 2.5 ft. Calling the performance of a square-point shovel on a wooden mat 100 per cent., the efficiency of a square-point shovel working on a rough bottom is only 60 per cent. while with a round-point shovel an efficiency of about 70 per cent. may be maintained.

Best Shovel for Mining Work

Fig. 34 shows the design considered best adapted to mining work. The blade should hold 21 lb. of broken ore as an average load. The approximate dimensions of blades for various ores are given in Table II; the dimensions on the illustrations are for Burro Mountain ore. Both the square- and the round-point blades should be of standard shape, of No. 15 gage at the point, and of such composition that the shovel will handle not less than 1100 tons of medium-hard ore when shoveled off a wooden mat. All blades should be of the plain back type without rivets, the back strap being welded to the blade. Only best-grade, second-growth, northern white ash should be used for the handle, which should be bent to the shape and dimensions shown. On short-handle shovels, the Dirigo, or split D, handle is preferred, as it is much stronger than the ordinary D handle.

A right-hand shoveler throws the ore from him from his right side. When using a short-handle shovel, he grasps the D handle with his left hand, the cross of the D being in the palm of the hand to obtain a good hold, and with the right hand takes a grip on the handle just back of the straps. Standing close to the material to be shoveled, with feet placed as in Fig. 35, he bends his back, shoulders and knees, and assumes a squatting position so as to remain well balanced on his feet. The left hand grasping the D handle rests against the left leg just above the knee, and the right arm below the elbow rests on the right leg. Without moving the feet, the whole body is lunged forward from this position, thrusting the shovel blade forcibly under the muck pile, and heaping it full.

To elevate the full shovel, the knees, back and shoulders are simultaneously straightened, the feet remaining motionless. To throw the ore into a car, after the shoveler has reached a nearly erect position, the shovel is raised farther by drawing up the arms, the left hand acting as a moving fulcrum, and the load is cast directly over the right shoulder without turning the body or moving the feet. To cast in a horizontal direction for any distance, the body must be turned part way around to the right and a short step made in the direction of the throw; the load is cast by a swing of the arms, first slightly backward to obtain momentum and then forcibly forward to deliver the load.

When using a long-handle shovel, a right-hand man grasps the shovel close to the end of the handle with the left hand and places the right hand just back of the straps. The feet are placed as in Fig. 36 and the body assumes a crouching position with knees bent and the right elbow resting on the right thigh just above the

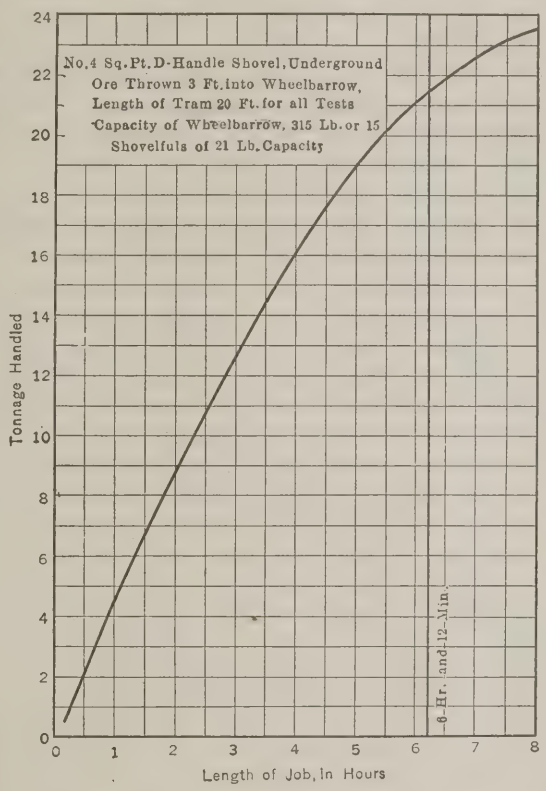

FIG. 32. SHOWING CAPACITY OF A SHOVELER USING A CAR FOR VARIOUS JOBS

knee. The handle of the shovel lies across the left thigh close to the groin and the left hand falls into position against the body near the waist. With a lunge of the body the shovel is then thrust under the mass of ore without moving the feet. To lift the mass on the loaded shovel, the back and shoulders are straightened and the load is brought up by using the left thigh as a fulcrum, over which the shovel handle works as a lever; the knees are then straightened to bring the shoveler into an erect position where the ore is cast directly over the right shoulder into a car as with the short-handle shovel. To cast the load horizontally, a turn to the right is made and a short step in the direction of the throw, exactly as with the short-handle shovel.

It is surprising what a small proportion of the men underground know how to use a shovel to the best advantage, and all sorts of tricks are resorted to in an

effort to lighten the work. Among these are: Taking less than a shovelful each time, using the foot in an effort to force the shovel into the muck pile in the manner of using a spade, skimming a thin layer of loose dust off the sides of the muck pile instead of energetically penetrating the mass to obtain a full shovel load, not holding the shovel properly, and taking two or three steps with each load.

To obtain the highest shoveling efficiency underground, every man hired as a shoveler should be in a particular stope or working place that is directly in charge of a shoveling boss. This boss should have had a large experience in shoveling, have learned correct shoveling methods, and should be able to instruct men and gain their confidence. Each man should be taught: (1) The necessity of using the correct type of shovel for any given purpose; (2) the proper way to handle a shovel; (3) the range of usefulness of wheelbarrow and car; (4) the advantage of using a platform to shovel from; when shoveling has progressed beyond the platform time should be taken to advance the boards or iron sheet and to scrape the broken ore forward on to the platform; (5) the mass of broken ore should be thoroughly loosened with a pick; it is waste of effort to try to shovel material that has become packed; (6) shoveling should be done at a good steady pace, the speed depending on the length of job; it is waste of time and energy to try to rush through the work; (7) in addition to the amount of rest inherent in the work itself—that is, the rest gained while picking down, tramming, etc.—definite rest periods should be maintained during the day. When each man has been thoroughly instructed in the methods of shoveling, he should be placed in general run-of-mine work among the more experienced shovelers, so that another new man make take his place for instruction.

Shovelers Should Work in Pairs

When possible to avoid it, a shoveler should never be made to work alone. Shovelers working in pairs produce the best results, as they set the pace for one another and compete to a large extent; besides, any laxness can be detected almost at once. Shovelers should be placed in groups of two, four, six, etc., so that the men can work in pairs. It is best not to have more than four men in any group, as with larger groups it is hard to watch the work of each man separately and they try to put the work off on one another. Best results are always obtained when the tonnage shoveled by each man, or small group of men, can be accurately measured at the end of every shift. When men are shoveling in a stope where there is room, they should be so placed that each can use a long-handle shovel; where the area is restricted, a short-handle shovel should be given to them and they should be placed so that a right-hand and a left-hand man can work together.

The ideal shoveling day is the period during which a man can rest at stated intervals and can produce the maximum tonnage by working at a steady pace for the full period, and yet not wear himself out, so that his health is impaired. It is obvious that a steady working pace for the full period is physically impossible unless the rest periods are excessive, in which case the total tonnage handled falls off; in other words, a man cannot do a good day's work and leave the job feeling as fresh as when he arrived. In all of the tests, the shovelers showed a decreasing efficiency, as the day advanced; rest periods brought up the efficiency, but after each successive rest period the efficiency did not advance to quite the same point as after the preceding period, and at the end of the shift it had reached its lowest ebb. Much work can still be done on this point, but after considering the amount of rest that is inherent in the work itself and the amount of added supervision necessary to maintain shoveling on a scientific basis, the tentative statement is made that, in addition to the lunch period, there should be two 10-min. periods of complete relaxation, one midway between the beginning of the shift and lunch time and the other midway between lunch and quitting time.

In all discussions of efficiency methods and wage payments, one fact must be recognized: unless a man feels that he is to be well paid for his work, he is going to use every subterfuge to keep those in charge from knowing just how much he is capable of doing. Almost without exception the workman will be most interested in his wage; if he can earn the same wage with less effort he will do so, and if an increase depends directly on his extra effort he will work harder. It is not the purpose to discuss wage payment and benefit work except in so far as the relation of wages to an efficiency campaign must be clearly recognized; but it is necessary that some thought be devoted to the method applying these standards so as to obtain the best results from day to day without antagonizing the men.

Fundamental Laws of Management

Three fundamental laws of management are: (1) The man must be contented with his surroundings and conditions of work; (2) he must have confidence in the desire of the men over him to be fair in their dealings; (3) the payment for the work done must be proportionate to the performance.

It must be obvious to any one that such things as accident insurance and compensation, good hospital service, old-age pensions, steady work for old and faithful employees even in times of financial stress, good housing and living facilities, improved sanitary conditions, good educational features, such as schools and libraries for both old and young, plenty of entertainment, such as a club, moving pictures, and lectures, and a sincere interest in the men by the management, tend to make the men happy and contented with their surroundings and to put them in a receptive mood for any bonus and efficiency systems that may be contemplated. Unless the men are contented, it is not possible to attempt to increase the efficiency by scientific study, as the men will at once become antagonistic to the time-study man and the efficiency engineer and will do all they can to mislead them.

No campaign for scientific management will be successful as long as the men feel that the company is trying to determine what each man can do merely to cut his wages and to make him work harder for a wage only slightly in advance of his old rate. The company should make each man understand that it hopes to determine what a fair day's work constitutes and that for a fair day's work it is ready and willing to pay a fair day's wage and to reward any ambitious and energetic man who does more than the average, by paying him

accordingly. The company must supply the best tools for the work and have the conditions such that the man can work to the best of his ability.

When first installed, a schedule of payment should always be a little too low rather than too high; then as the men fail to make a good bonus the schedule can be increased from time to time as occasion requires. A schedule should never be lowered when once it has been put into effect, as the men will immediately become suspicious of the intentions of the management. The new system should be introduced by applying it to one man at a time, picking out only those who are willing; after several of the best men are working under it, with demonstrated advantage to themselves, most of the others will volunteer to come under the new system. In general, it takes two or three years to institute a new system and to put it on a successful operating basis without making the men suspicious, and the utmost patience and tact is necessary at all times.

The Phelps-Dodge Corporation has not as yet introduced a system of payment other than the regular daily wage and, in the case of development work, the contract system, in which the shovelers share by receiving a higher wage than the men in the stopes.

Daily Wage—In the daily-wage system, the supervision is generally held at a minimum and the men have an ideal opportunity, and use it to the full extent, to do as little for their pay as possible. It is a system of payment that is by no means adapted to efficiency methods, as it puts the men into large classes and takes no account of individual effort.

Task Work—The task-work system merely designates a piece of work to be done after which the laborer may go home. In some cases the laborer gets a full day's pay for the period he works, while in others he divides with the company the amount of wage for the time he saves. In either case his only reward is shorter hours; he does not make any more by working harder, in which respect the system falls short.

Profit Sharing—The men receive a set wage for a day's work and at intervals (quarterly, half yearly or yearly) a certain proportion of the company's profits are divided among them, either according to wage rates or to length of time in the service of the company. This system has the disadvantage of not giving immediate reward to the men for the work they are supposed to do in return, and as a result their interest is not stimulated.

Piece Work—In the piece-work system, the men receive a set price per ton handled or per foot advanced, etc. The system is an ideal one when the conditions of work vary only within narrow limits, but underground it has grave drawbacks. When a piece-work price or a contract is given, often the workman will make too much

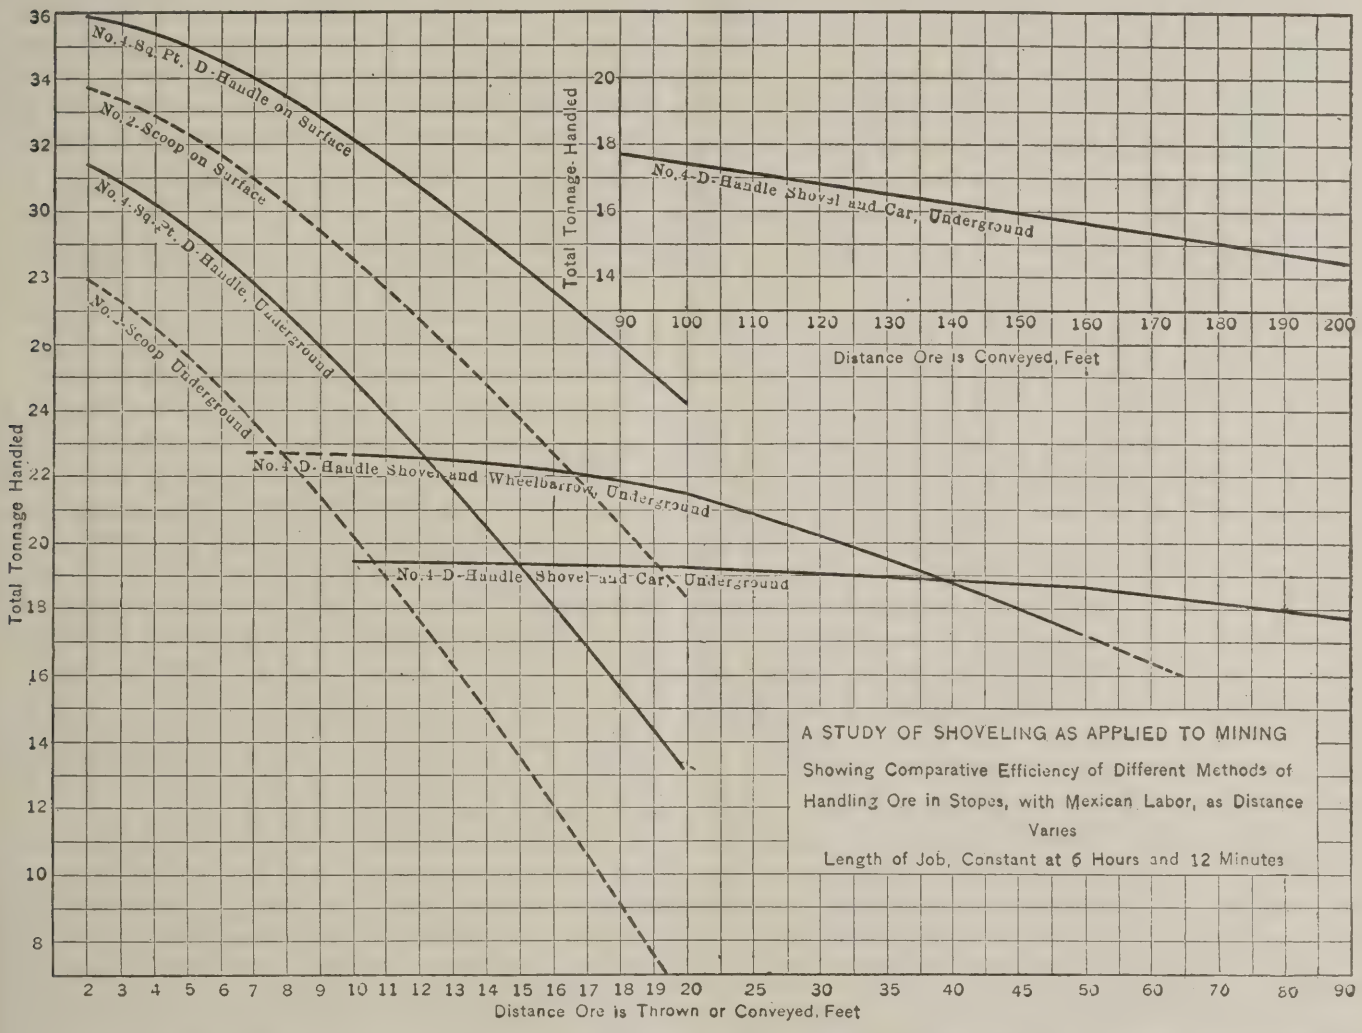

FIG. 33. COMPARATIVE EFFICIENCY OF DIFFERENT METHODS OF HANDLING ORE AT VARYING DISTANCES

money or not enough; the price set is seldom one that enables the man to make what the company thinks is fair. In the first case, the company is tempted to cut the price; in the second, it is forced to help the man out by giving him enough to live on. Many unions forbid the piece-work or contract system. The harm in cutting rates is largely caused by poor judgment on the part of the management in first setting the rates. The standards are not based on scientific data, but on the previous best records, an ordinary try out, or on the foreman's off-hand estimate of what should be done, all of which are generally from 50 to 150 per cent. too low.

Conditions underground vary to such an extent from day to day that no true contract or piece-rate system can be entirely fair, and either the man or the company is bound to suffer. Just as soon as the men in charge of such a system try to anticipate the conditions in making contracts, the men raise the cry of favoritism and become dissatisfied. Such a system presents great opportunities for evil in that the effort to equalize results actually does produce favorites and offers a field for a dishonest man to profit from the laborer.

TABLE IV. BONUS PAYMENTS TO BE APPLIED TO SHOVELERS. BASE RATE OF $3.75 PER DAY IS GUARANTEED TO MAN

Bonus System—The bonus system guarantees a fair wage to the man for everything that he does up to a certain standard performance and beyond that a bonus is paid for each unit of work done. In my opinion, it is an ideal system for getting around all the difficulties and uncertainties that exist in mining. To install such a system requires much preliminary study, and unremitting care during its existence, but if carefully carried out it creates a bond of sympathy and good feeling between the men and the company that is worth far more than the expense. It simply means that for any class of work the company must determine through the medium of past performance and time study what an average day's work shall consist of and must guarantee the men a fair day's wage for that amount of work. In order to keep the men interested and up to this standard, the company must say that it is ready and willing to pay for any work done in excess of the required standards.

The wage in force at the present at the Burro Mountain mines for Mexican shovelers is $3.40 a day. Assuming that this is a fair wage for this class of labor, to put the men in the proper frame of mind to take kindly to the bonus system, the wage should be raised to $3.75 a day, an increase of 10.3 per cent.; this wage will be paid to them whether they make the required tonnage or not. If any man makes the tonnage required of him, his wage may be raised to $4 for that shift, an increase of 17.6 per cent. above the $3.40 rate, although this has not been designated in Table IV. If he produces anything over the required amount, he should be paid a bonus per ton, depending on the original task allotted to him. In order to make an increase of 50 per cent. over his old $3.40 rate, a shoveler will have to produce between 25 and 30 per cent. more than his allotment. Experience has shown that when a laborer receives an advance in wages of more than about 50 to 80 per cent. above a fair wage, he tends to become shiftless and the increase does him more harm than good.

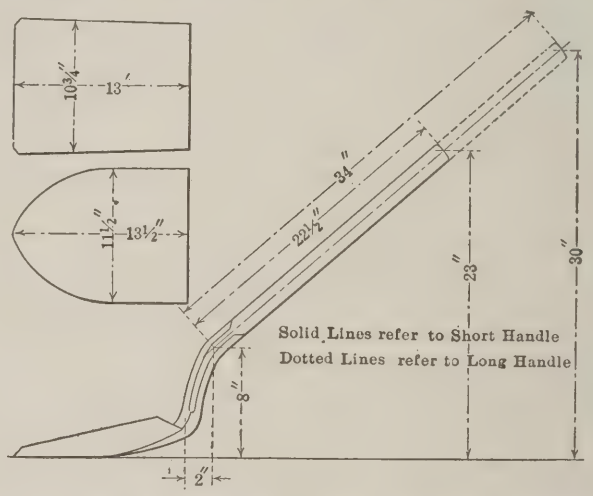

FIG. 34. DESIGN OF SHOVEL BEST ADAPTED TO MINING WORK

Fig. 33 shows that under good working conditions a laborer moving ore 20 ft. should use a wheelbarrow, and should move 21.5 tons. According to Table IV, this man will receive $3.75 a day for any work up to 21.5 tons, or at the rate of $0.175 a ton. If he reaches the required 21.5 tons, his wage will become $4, or at the rate of $0.185 a ton, and for every ton over the required amount, he will receive $0.185 a ton. In each individual case, the man setting the standard of work should make sure whether there are any interfering elements that will prevent the man making the standard tonnage, in which case he should make a fair reduction.

In 1917, in a stope with raises spaced 25 x 65 ft. from which was mined 145,000 tons, the shovelers averaged 8.5 tons a man, with wages at $3.40 a day. This shoveling cost $0.33 a ton, assuming that the men were on other work for 17.5 per cent of the day. Charts show that under the new system these men should have averaged 22.9 tons a man, for which they would have received $4 a day. This would be an average shoveling cost of $0.175 a ton, or a gross saving of $22,475 for the year. Out of this gross saving would have to come

the cost of, say, five special men, at an average salary of $160 a month, or a total of $9600 a year, to take care of this branch of the work. This sum deducted from $22,475 leaves a saving of $12,875, or a total shoveling cost of $0.239 a ton.

If, under the new system, the men consistently fail to make bonuses, it is either the company's fault or the men's fault. If it is the fault of the company, the

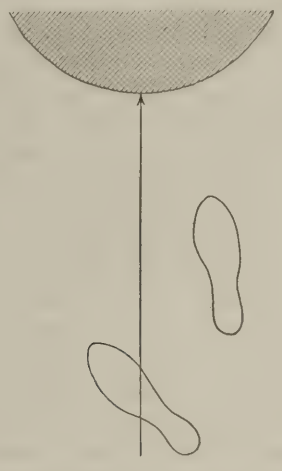

FIG. 35. POSITION OF FEET OF RIGHT-HANDED MAN USING SHORT-HANDLE SHOVEL

standard may have been set too high on account of a faulty analysis of the time-study figures. The men may not be receiving the proper shovels to work with; or the men in charge of the work may not be making fair reductions from this standard, when working conditions are poor. If the men are to blame, either they are not physically fit to be shovelers, in which case they should be tried out at some other work, or they are suspicious of the company's motives, which would lead one to suspect that the system had been introduced too hastily, or that the men have organized to force the company to raise the rate of payment or to lower its standards.

Summary and Conclusion

Shoveling ore cost so much at Tyrone during the year 1917 that it was deemed advisable to conduct tests to see where the fault lay. These tests were in the nature of time studies and extended over a period of nearly a year. No data were available on this work to supply a starting point, so it was necessary to begin in a very elementary way, to find out the capacity of the average Mexican laborer.

To obtain a basis for comparison, it was necessary to determine the capacity of various types and sizes of shovels, so as to know whether the 21-lb. load was the best load underground as well as on the surface. A list of essential factors influencing shoveling was also made out during the course of a short series of preliminary time studies, and the motions involved in shoveling were analyzed and subdivided for convenience in studying. The necessary forms and record sheets were also decided upon at this time. A second short series of tests was then conducted on the surface, so as to be able to estimate the negative effects of underground work on the shovelers, and to minimize, as far as possible, the need for studying obviously poor types and sizes of shovels under the difficult conditions to be encountered in the mine.

The test work underground consumed by far the greater proportion of the time and was divided into three series: Shoveling directly into a chute; shoveling into a wheelbarrow and tramming to a chute; and shoveling into a car and tramming to a chute. In each series the following points were determined for various lengths of time worked: Number of shovelfuls handled per minute, effect of distance thrown on shoveling speed, amount of rest required, amount of time consumed in tramming and dumping, proportion of working day occupied in shoveling, total tonnage handled during various working periods, effect of distance on tonnage handled during the day.

These tests showed that the design of the shovel has a marked effect on the shoveling efficiency and that with the proper weight and size of tool the man's efficiency will be increased in spite of himself. It was demonstrated that a man handling a total load of 26 lb. and 8 oz. did the greatest day's work, other things being equal, and that this load is divided into a live load of 21 lb. and a shovel weight of 5 lb. and 8 oz. A shovel weighing 5 lb. and 8 oz. made out of the best composition steel gives excellent service, and a lower cost per ton than a shovel having a lower first cost.

Further marked increases in shoveling efficiency are to be gained by instructing the shovelers in the proper methods of using a shovel, a thing that few laborers know in spite of the fact that they may have been shoveling for a living for years.

Probably the most important part of all efficiency work lies in the wage that is paid to the men, the manner of paying the wage, and the feeling of confidence and good will that exist between the men and the company. Various types of wage payment are briefly discussed and the conclusion is reached that the bonus system in some form, if properly handled and carefully watched with a sufficient number of specially trained men to instruct the laborers and keep them working

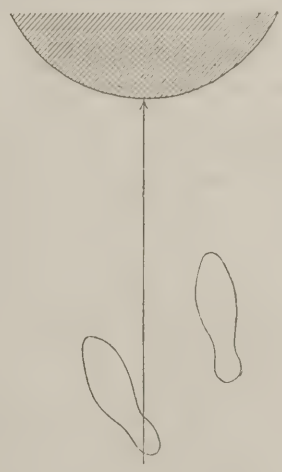

FIG. 36. POSITION OF FEET OF RIGHT-HANDED MAN USING LONG-HANDLE SHOVEL

to the best advantage, is the preferable system of payment. A bonus schedule is proposed as a starting point for the work and the benefits that will probably be derived from it are outlined, using some actual stoping experience as an example.

Scientific management systems applied to certain eastern factories have demonstrated conclusively that the efficiency of the average workman can be increased by

from 50 to 250 per cent. and that at the same time the men will receive better wages, will remain in better health, and will be happy and contented, while the company will actually produce its products at a lower cost.

F. W. Taylor, working at the Bethlehem Steel Co. plant several years ago, increased the capacity of the iron-ore shovelers from 16 to 59 tons per day per man, raised the men's wages from $1.15 to $1.88 a day, and at the same time decreased the operating cost from $0.072 to $0.033 per ton shoveled. The increase in shoveling capacity amounted to 269 per cent. Figures obtained at Tyrone indicate that the tonnage in at least one of the large stopes can be raised from 8.5 tons per man to 22.9 tons per man, an increase of 169 per cent., the wages can be raised from $3.40 a day to $4 a day, and the cost to the company reduced from $0.33 a ton to $0.24 a ton, after taking care of all extra supervision needed. In addition to this actual saving in shoveling costs, the overhead and general mining costs will be reduced per ton by mining a greater tonnage per man; and the other classes of labor such as machine miners and timber men will be able to do more work, as they will not be hampered and delayed by the shovelers to such an extent as at present.

Labor should not be given too much of an increase in wages over what is recognized as a fair living wage, as the men will at once tend to become shiftless and prosperity does them more harm than good.

The modern manager is beginning to see that the relation of standard times to the other features of organization is close and vital. The determination of the standard, or the shortest time, in which a job can be done, is the starting point for all work that has as its aim the establishing of an equitable wage system.

Charles Piez Talks to Engineers On Shipping Problems

The Engineers' Society of Northeastern Pennsylvania held its twenty-second annual banquet at the Hotel Redington, Wilkes-Barre, Penn., Feb. 5. About 390 persons were present, more than the banquet hall would accommodate. The toastmaster was Daniel R. Reese, and the guest of honor, Charles Piez, director of the Emergency Fleet Corporation and president of the Link Belt Co.

Mr. Piez made a most interesting address, completely justifying the work of the Emergency Fleet Corporation. He said that wages to ship workers had been increased to accord with the cost of living, but that it had been felt that it was questionable always whether the Macy board, which regulated the matter, would continue to be justified in making such adjustments, because there were large bodies of workingmen in the United States whose difficulties in meeting the high cost of living were not being, and could not be, so generously met. In fact these men were bearing the pressure of war conditions, whereas the shipbuilders were, by the frequent readjustments, managing to avoid feeling any of the pressure. Mr. Piez declared that the United States should write off about a billion and a half dollars as a war loss. Conditions were not favorable for economical production. Above all the wooden vessels were not really suitable for modern commerce. Such vessels could not be built to carry a deadweight of more than 3500 to 4000 tons. Such a load, when the coal supplied for going and returning was deducted, would be found inadequate for modern competitive conditions. The trouble was not that the ship was wood—a steel ship of the same size would be equally uneconomical—but being a wood ship it could not be made bigger.

He declared himself opposed to a merchant marine larger than would serve for the support of the increased navy. The figure he named was 12,000,000 deadweight tons. He declared that 25,000,000, as had been suggested, was altogether too large. He added that in order to operate the merchant marine with the wages demanded by the union and the working conditions specified by legislation it might be necessary for the nation not only to write off much of the money expended, but to guarantee that it would accept part of the losses of operation of any company which would undertake to sail the ships and provide the docking accommodations.

Con McCool, a one-time miner, delighted the audience by his witty stories and his clever impersonation of the men of divers nationalities engaged in a labor convention. The outgoing president read his report for 1918 and the placid G. F. Smith, ingoing president, delivered some extremely humorous remarks on his experiences at the Club of the Engineers' Society during his bachelor days. The Club much appreciated his dry wit.

There were at one time 43 blue stars in the service flag of the society, but three have turned to gold. They represent Lieut.-Col. Frank F. Duffy, who fell at Château-Thierry, Ensign Merritt H. Barnes and Captain Karl G. Van Sickle. Dan Hart, a Wilkes-Barre man, delivered an eloquent address in commemoration of their services, and preliminary arrangements were made for a memorial in their honor. The motion picture, "America's Answer," concluded the entertainment.

Colliery Notes

Miners often do not object to working in seams generating gas as it helps to work the coal. Another important thing in this connection is that the air is often better; the gas must be diluted by enormous volumes of air when given off in large quantities at the face.

An inside company man ran a small sliver in his finger and infection resulted because he did not have it dressed. The Bethlehem Steel Co. has an excellent rule covering such cases, which requires all the employees at its Bethlehem plant in event of any injury whatsoever to report at once to the physician in charge of such matters at the company hospital at the works.

The U. S. Bureau of Mines reports 76 men killed about coke ovens in 1917 compared with 45 in 1916, while the total number of men employed about ovens remained about the same—32,417 for 1917 and 31,603 for the preceding year. The fatality rate in 1917 was 2.14 per 1000 employees; in 1916 it was 1.32. The injury rate in 1917 was 188.59 per 1000 men employed, while in 1916 it was 153.49. The increase in accident rates is not necessarily on account of the work being more hazardous; rather it is due to the keeping of better records which more nearly represent true conditions.

Book Reviews

Where Differences Wait on Reason

REPORT OF ANTHRACITE BOARD OF CONCILIATION. Vol. VI, 363 pages; 6 x 9⅜; no illustrations. James A. Gorman, secretary, Anthracite Board of Conciliation, Hazleton, Penn. Cloth Boards.

The volume of business transacted by the Anthracite Board of Conciliation will be appreciated when this record, covering a period from Apr. 1, 1916, to Mar. 31, 1917, is scanned. In a preface we are assured, however, that it does not cover all the activities of the board. "The members of the Board of Conciliation, acting pursuant to regulations, settled," says Mr. Gorman, "a large number of grievances in their respective districts, thus making it unnecessary to bring up these matters formally for action by the entire membership. In such grievances the parties directly interested were not required to appear before the board to give testimony. Grievances settled in this way are not recorded in this compilation of the work of the Board of Conciliation as the board in these compilations makes record only of the formal grievances which were taken up and acted upon by the whole body."

The number of grievances decided and withdrawn number 175, the registration numbers running from 361 to 569. Certain grievances being at the date of record neither decided nor withdrawn, the number recorded is reduced from 209 to 175, as noted. Cases were withdrawn for various reasons, "the chief of these being, compromise by parties to grievances, settlement direct, failure of interested parties to prosecute their cases before the board, complainants quitting the employ of the company and complainants requesting withdrawal of their cases."

Among other *causes celébres* was the case of the motor runners of the Hazleton Shaft Colliery vs. the Lehigh Valley Coal Co., where the motormen wanted to receive the same wages as were paid to oil-locomotive engineers at the same colliery and to motormen at other collieries. Another case is that of the contract miners of No. 23 Tunnel, Coal Brook Colliery vs. the Delaware & Hudson Co. relative to pay for lifting the bottom impurity or rock as part of the coal seam. There is also the case relative to the subletting of contracts for the loading of machine-mined coal known as Grievance No. 384 and entitled "Certain Employees vs. Delaware, Lackawanna & Western R.R. Co., Coal Department." The volume also reports the "Topping" dispute at the Short Mountain Colliery of the Susquehanna Coal Company.

In every man's life, in the life of every industry, in the life of every nation, there are only three choices—submit, arbitrate or fight. It is creditable to the coal industry of the anthracite region that the second course, which is the best of all, has been the course accepted. The bituminous coal industry has as yet no court of final appeal that is in any degree comparable with that long established in the anthracite region. Other industries also straggle far behind along the road over which the anthracite industry has traveled with winged feet.

Burning of Comminuted Coal in Industry

POWDERED COAL AS A FUEL. By C. F. Herington, Mechanical Engineer. Pages XII + 202 + 9 index; 5¾ x 9¼; 84 illustrations. D. Van Nostrand Co., 25 Park Place, New York, Publisher. Cloth boards. Price, $3 net.

Many are the inquiries on foot to ascertain the possibilities of powdered coal. Some of the emphasized disadvantages in the use of this fuel are merely superficial. We realize from the first that it is prepared coal, and therefore more costly than slack. We overlook the fact that the drying to 1 per cent. of moisture is not a costly performance. Every ton of coal burned, no matter what the conditions of burning, is desiccated that much, either before it is put into the furnace or after it is put in.

The work of drying is doubtless more troublesome when it is a separate operation, but theoretically, at least, the loss of heat is the same. Coal must always be dried in the burning. All that we call water vapor in the coal must be eliminated sooner or later. In the powdered-coal system it is eliminated in two stages, in the grate system in only one. In either case, out of the coal the moisture must be driven, and thermal units must be consumed in its expulsion.

Then, again, the powdered-coal system is prodigal in the cost of crushing but is frugal in the cost of stoking, though, of course, not more frugal than the mechanical stoker. Perhaps few realize how far the powdered-coal plant has monopolized the cement industry. According to C. F. Herington, "fully 90 per cent. of the Portland cement made in the United States is burned in kilns in which powdered coal is the fuel." In metallurgical processes powdered coal seems to have great advantages over oil.

The book gives information about the suitability of various coals for powdering, the machinery used in coal powdering, the feeding and burning of powdered coal, the use of powdered coal in the cement industry, in reverberatories, in metallurgical furnaces and under boilers. The developments in locomotive firing follow.

Then explosions of powdered coal are treated. The author seems to carry us back to the end of the last century. He appears anxious to make us think that coal dust, while it may burn, will not explode. It would be delightful if we could believe him. He has had long experience in cement plants. Others in the nineties had worked even longer in the mines, yet still would not believe in the explosibility of coal dust. "In 1915," the book says, "Thomas A. Edison, in explanation of the so-called explosion that took place in his cement mill some years ago, said: 'The explosion was occasioned by fine coal dust catching fire and burning slowly in a pit, thus forming an explosive gas in the air. The explosion killed five men. Please let me emphasize the fact that it was not the dust itself that exploded.'"

A good bibliography concludes the volume. There is no question that such a book has long been needed, and this monograph will be welcomed by the profession.

New Organ of Corporate Good Fellowship

SOLVAY FOLK. A magazine published monthly for the benefit of the employees of the Solvay mining interests. 32-page pamphlet, 8 x 10¾ in.; well illustrated.

A new house organ has just been added to the steadily growing number of such publications. It is published by the Solvay interests, which have mines at Kingston and Westerly in Fayette County, West Virginia; at Marytown, Big Sandy, Orkney, Warwick, Harvard and Exeter in McDowell County, West Virginia; at Spington, Mercer County, West Virginia, and at Tolland, Coaldale, Henry Clay, Big Branch, Lookout and Freeburn in Pike County, Kentucky. The editor, who keeps his name hidden for some strange reason, has done spendidly. His pages make the right appeal to the eye, though a little greater uniformity in the style of his box heads and a few minor typographical changes would better satisfy the appreciative and the reasoning faculties. The pamphlet has a children's page, a household page, a page full of jokes entitled "Bug Dust," and several pages of local gossip from the various mining centers where the Solvay-process coal is mined.

The psychology of these house organs is interesting. A man is invited to make a speech. Having accepted, his first thought is to please. "To please," the idea gets into his head as an obsession. This good feeling grows mightily as he schemes how he can please his audience. What an excellent effect will the desiring to please which a house organ creates have on the persons publishing the organ.

Secretaries of Local Coal Associations to Cooperate with Geological Survey

Local coal associations throughout the country have been unanimous in their pledge to coöperate with the United States Geological Survey in the collection of coal statistics. In designating the secretaries of local associations as representatives of the Geological Survey, the following letter sent to W. E. Blucher, of the Southwest Coal Bureau, is typical of the other letters of appointment:

In accordance with the informal discussion had between you and Mr. Lesher, Geologist in charge of Mineral Fuel Statistics, I take pleasure in designating you, as Secretary of the Southwest Coal Bureau, the representative of the Geological Survey in the matter of collecting and compiling current statistics from the coal operators of Iowa, Missouri, Kansas, Arkansas, Oklahoma and Texas relating to the progress of the coal industry in those states.

I appreciate very much the spirit of coöperation on the part of yourself and the operators in your district in entering into this coöperative arrangement, and believe that the results, both immediate and ultimate, will be to the advantage of the local industry as well as to the Geological Survey and will promote a better understanding and closer sympathy between the Department of the Interior and the producers of coal.

You are authorized by this letter to use, in your correspondence on the subject of current production and distribution statistics, the letter heads bearing the caption "U. S. Geological Survey, in coöperation with the Southwest Coal Bureau" on the general form of the sample inclosed, and to use the same captions on your envelopes and report forms. Your correspondence with the operators must necessarily carry the regular postage.

Secretaries of local coal associations, which to date have been designated representatives of the United States Geological Survey to assist in the gathering of coal statistics, are as follows: Jones Waffle, Indiana Coal Trade Bureau, Terre Haute, Ind.; C. M. Roehrig, Northeast Kentucky Coal Association, Ashland, Ky.; Charles O'Neil, Central Pennsylvania Coal Operators' Association, Altoona, Penn.; James A. Fenelon, Coal Trade Bureau of Illinois, Galesburg, Ill.; J. E. McCoy, Southern Appalachian Coal Operators' Association, Knoxville, Tenn.; O. G. Scott, Central Illinois Coal Bureau, Springfield, Ill.; W. E. Blucher, Southwest Coal Bureau, Kansas City, Mo.; F. B. Reimann, Northern Pennsylvania Coal Operators' Association, Butler, Penn.; F. J. Patton, Northern West Virginia Coal Operators' Association, Fairmont, W. Va.; D. F. Hurd, Pittsburgh Vein Operators' Association of Ohio, Cleveland; W. B. McKinney, Southern Ohio Coal Exchange, Columbus, Ohio; George Beausewine, Jr., Operators' Association of Williamson Field, Williamson, W. Va.; W. E. E. Koepler, Pocahontas Operators' Association, Bluefields, W. Va.; G. D. Kilgore, Southwestern Virginia Coal Operators' Association, Norton, Va.; E. R. Clayton, Harlan County Coal Operators' Association, Harlan, Ky.; C. J. Fletcher, Knox County Coal Operators' Association, Indianapolis; H. M. Little, Southern Indiana Coal Bureau, Evansville, Ind.; P. H. Greenlaw, Fifth and Ninth District Coal Bureau, St. Louis, Mo.; C. Ostrom, Northern Illinois Coal Operators' Association, Chicago; W. B. Innes, Western Coal Producers' Association, Billings, Montana; John G. Kerr, Colorado Coal Operators' Association, Denver; J. P. Wilson, Tug River Coal Operators' Association, Bluefields, Va.

National Coal Association in Readiness to Transmit Market Information

To carry into effect its market information service, the National Coal Association is proposing to open branch offices at Pittsburgh, Chicago and other cities. Each branch office will be the head of the tributary district. Reports are to be collected each day of the preceding day's sales. From the several reports, an analysis of the market situation will be made and telegraphed to the local association's secretaries for distribution to members. The bulletin probably will give the number of cars sold, the prices obtained, the kinds and sizes of coal and the class of customer, with a distinction between spot and contract sales.

Secretary Redfield Plans Cooperative Action Between Government and Industry

The Secretary of Commerce has proposed a plan for coöperative action between the Government and industries with the idea of stabilizing prices and meeting problems of readjustment. Secretary Redfield expects to call conferences of representatives of the various industries. He states, however, that the conferences will be first with the steel, copper, cement, lumber and other industries. The conference with the representatives of the coal industry probably will be left until the last, as fuel enters into all the industries and coal questions can be discussed best after the problems of the other industries have been discussed.

Employees of the Fuel Administration on Feb. 10 entertained Cyrus Garnsey, the assistant director of the Administration, at a smoker. During the evening, Mr. Garnsey was presented with an expensive watch.

Recommend that Tidewater Shippers Need Not Be Members of the Exchange

Recommendations have been made by the Tidewater Coal Exchange that it no longer be compulsory for shippers to tidewater to be members of the Exchange; also that operators may ship directly to consumers. It also was recommended that pre-war demurrage be restored.

The meeting of the tidewater shippers was held in the National Coal Association assembly room, but the National Coal Association was in no way a party to the conference, as has been stated in some quarters. John Callahan, of the National Coal Association, did act as chairman, but for a short time only, so as to permit of the selection of a chairman to preside over the meeting. A committee was authorized on which will be representatives of shippers to each of the tidewater ports.

Railroads to Make Prompt Settlement of Coal Freight Claims

Means will be found in the near future by the railroads to make prompt settlement of freight claims on coal. This is the most definite result of the conference held in Washington between the Railroad Relations Committee of the National Coal Association and the committee consisting of fourteen of the principal claim agents. New regulations are to be drawn up for the settlement of freight claims on coal. Another matter which brought out much discussion was the matter of who is responsible for the loss of coal when there is no prima facie evidence of loss. The meeting was described as a very satisfactory one, and it is believed that much more satisfactory handling of freight claims on coal will result.

Motion Picture Reels of Mining Industry Soon Ready for Distribution

Through the coöperation of many of the large mining and metallurgical companies throughout the country, the Bureau of Mines has been able to obtain many excellent motion picture reels showing the various phases of the mining industry. In all, the Bureau of Mines has now in its possession about 250 reels, and after these have been edited and captioned it is thought that this collection will be distributed at once.

It is the intention of the Bureau to loan these reels to mining schools and other engineering institutions throughout the United States. Effort will be made to keep this collection up to date, and to obtain reels from time to time that will show the progress that is being made in the mining industries. The supervision of collecting these reels, assembling them, and the distribution of the same, has been placed in the hands of Morton F. Leopold, safety engineer of the Bureau of Mines.

No agreement has yet been reached in regard to railroad fuel purchases, although it is believed that the Railroad Administration is convinced that publicity must be given to bids. The matter of district prices and distribution of orders within districts is still under discussion.

Revival of Interest in Peat Resources of the United States

Interest in peat has been revived to some extent by the recent act authorizing the Bureau of Mines to make an investigation of that resource. There are in the United States, according to C. C. Osborne, of the United States Geological Survey, 11,000 square miles of peat bog containing more than 12,000,000,000 tons of peat fuel. A ton of machine-made peat is equivalent, for heating purposes, to 1.3 tons of wood; one-half ton of bituminous coal and six-tenths of a ton of anthracite coal. With Europe using 20,000,000 tons of peat annually, in the production of heat and power, it is believed that no insurmountable economic difficulties stand in the way of utilizing some of the peat deposits in this country. Massachusetts and Maine are at present engaged in investigations of peat deposits in those states. With increased rail rates and the scarcity of shipping, it is believed that New England peat could be used to advantage in the areas within short distances of the deposits.

E. R. Lloyd has been appointed to succeed John D. Northrop as the geologist in charge of petroleum statistics for the Geological Survey. Mr. Northrop has resigned to enter the employ of an oil company operating in Wyoming.

Branch offices of the National Coal Association will be opened in Pittsburgh and in Chicago probably by Mar. 1. J. D. A. Morrow, the secretary of the Association, has returned to Washington after completing arrangements for these branches.

Legal Department

TAXATION OF COAL IN PLACE—Coal in place, being subject to ownership apart from the surface, either by grant of the coal by deed or reservation of it in a conveyance of the surface, thereby creating a fee simple title to the same as realty, is subject to taxation as real estate. But where the actual existence of coal under a particular tract of land is purely conjectural the interest is not subject to assessment for taxation at more than a nominal valuation. (Iowa Supreme Court, In re Colby, 169 Northwestern Reporter, 443.)

ILLINOIS WORKMEN'S COMPENSATION ACT—If a motorman in an Illinois mine was killed in the course of his employment, his surviving widow was entitled to an award under the Workmen's Compensation Act of the state, although they were living apart at the time of the accident and she was not dependent upon him for support; her rights being fixed by the fact that he was under legal obligation to support her. (Illinois Supreme Court, Smith-Lohr Coal Mining Co. vs. Industrial Commission, 121 Northeastern Reporter, 231.)

WHO MAY RECOVER FOR MINER'S DEATH—If there be a reasonable expectation of pecuniary advantage from a person bearing family relationship to another, the destruction of such expectation by negligence occasioning the death of him from whom it arose will sustain recovery of damages. Within this rule the parents of an adult miner can recover damages for negligence of his employer resulting in his death, where it appears that the decedent had sent money to them and that he intended to contribute to their support. (Gosh vs. Lehigh & Wilkes-Barre Coal Co., 68 Pennsylvania Superior Court Reports, 63.)

EDITORIALS

Plans To Reduce Illiteracy

A BILL has been introduced by Senator Hoke Smith of Georgia, appropriating $12,500,000 a year for four years for the purpose of wiping out our national illiteracy. Each state receiving its part of this appropriation will have to pass laws compelling "the instruction, for not less than 200 hours per annum, of all illiterate minors, or minors unable to speak, read or write the English language, more than 16 years of age, at schools or places or by other methods of elementary instruction, until such minors have completed a course of English generally equivalent to that supplied by third-grade schools."

Each state will also have to expend an equal amount in promoting the purpose of the Federal appropriation. The money to be appropriated by the United States is to be used solely for the compensation to teachers, superintendents and directors of education engaged in the education of such illiterates.

Every state accepting the appropriation must provide all the necessary buildings and equipment without Federal assistance. The money may not be expended for any religious or privately owned and conducted school, but apparently nothing is said about the coeducation of whites and colored people. This matter will be left to the judgment and predilections of the various states, and really it seems better to allow that degree of self-determination regarding a matter that arouses the bitterest of feeling. However, it is the wish of the public to wipe out colored as well as white illiteracy. The Federal control should be properly exercised to see that the training imparted to illiterate negroes is as competent as that provided for illiterate whites, except where a difference in language makes the teaching of the whites a work requiring greater expertness in the instructor.

The training will cover not only reading, writing and speaking English, but instruction in the "fundamental principles of government and citizenship, the elements of knowledge pertaining to self-support and homemaking, and in such other work as will assist such illiterates and foreign-born persons for successful living and intelligent American citizenship."

The weakness of the bill is that it does not require state legislation to compel adult illiterates to attend school. Our laws should compel every foreigner who steps foot on our shores to study English at a properly approved private or public school during the period of his stay here, unless he has already something more than a smattering of such instruction or receives a Governmental permit. No one can be a safe citizen of our republic unless he can understand the laws and purposes of our people.

The coal-mine operators have a keen interest in this matter. Everything that makes the personnel intelligent enables the operator to put in force plans for larger production and safer operation. A mass of unintelligent workmen is likely to be not only dangerous but also so incompetent that no progress in methods is possible. The education of the American workingman is largely responsible for his superiority as a producer to all other workingmen the world over.

After all, muscle is not the main requirement. It might have been so before James Watt and Michael Faraday revolutionized the world. Daily we are learning that taking thought is as productive as taking action. We can never put any new plan into effective operation without the support of a large number of men able to understand English and to act without having every detail explained to them at laborious length by an interpreter. If the new scheme of Senator Smith is made operative, the nation will take a stride such as has not been achieved for several decades.

In the matter of American shipping it is time we got down to bedrock on the facts in the situation. We declare it is our purpose to get American ships into all the ports of the world. This can be done only if we are willing to pay for it. The ships of other nations will carry the world's freight unless American ships afford the shipper equally low rates. It is unlikely the leaders of labor in America will sanction the repeal of the Seamen's Law, permitting our shipowners to hire whom they please, treat them as they please, and pay them what they please. The only other way is for the nation to pay a sufficient subsidy to shippers to permit them to meet foreign competition. Either the industries of America must share the burden of this subsidy, or we must abandon our shipping ambitions.

Parallels of Latitude and Meridians of Longitude

BUSINESS runs from the equator toward the poles and from the poles to the equator more readily than along parallels of latitude. Because the British and French produce what we produce, we prefer not to buy from them. Because we make what they make, they do not like to buy from us. Business along the parallels of latitude is largely distasteful to peoples engaging in it. It is competitive business. Trade reaches its largest proportions in the north temperate zone because of the populousness of that portion of the globe, and because of the relative sparseness of the population near the equator; not because the exchange of products flows naturally out of the mutual needs of those by whom the exchange is made.

It is a pleasure to do business with a planter or merchant in Nigeria or Colombia. He sends us such things as we do not have and badly want. He takes from us what the natives do not and cannot make. From the equatorial zone we get rubber and elephant's

tusks, copra and tin, spices, strange fruits, tea and coffee. No one wishes to exclude these and other tropical products. Rather we worry at times because we may not get them. On the whole, we would sooner do business with savages than with our own kind. Even the art and the trinkets of India, Central Africa and Brazil appeal by their differences; and their lands are natural places for us to sell our distinctive wares. With such people we can do all the business we please, and do it with the kindliest of feelings. When we exchange goods both parties feel they are receiving a benefit. Strange to say, the equatorial countries have little coal, or believe that they have little, though we cannot determine satisfactorily why this is so. For this reason they will accept a little coal, and the northern and southern countries are able and willing to supply them. This coal, universal as it is, might readily go to the equatorial regions were there much demand; but unfortunately for us, the equator needs no domestic heating and has few manufactories.

The population of the equatorial region is small, the people are in large part Indians and negroes, and therefore uneducated; the people, of whatever color, are not as hustling as we are, owing to the excessive heat of the sun. If it were not for this all industry would travel along meridians rather than along parallels of latitude, and trade would be complementary rather than competitive. We would fill the equatorial needs and the equator would fill ours.

At a basket picnic every woman brings her contribution of good, fresh and wholesome food. She has pride in its quality and quantity. We all are bringing our baskets to the common table. Some bring as little as they can and that little is bad and useless. If we all strive to bring less than another, how shall we all fare better? Let us strive so earnestly that when we open our baskets at the public fiesta they will not be an unworthy contribution to the public necessities. Otherwise ours truly will be a miser's mess.

When Industry Stumbles

ON THE whole the mining industry is reasonably free of strikes, but there is an undercurrent of discontent which may, at any time, make trouble. The coal industry is face to face with a spirit which finds a reason for wage increases in every development.

During the war the need for coal was acute. The mine worker saw in this fact an opportunity to urge the importance of high wages. "If they are not granted," he cried, "the industry will be deserted for other war industries. The operator must pay larger wages, if not for our sake at least for his own." Now the war is over and business is slack there arises another plea. "With short time we cannot make a living. Wages must be raised so that a man may work short time and keep up his living standard."

In former days it used to be said that wages must be lowered so as to encourage business. We have changed all that. Now, when demand falls, we raise the wages of the workers. When the camel of industry stumbles he comes down low enough that we can chuck on another case. Thus the more it stumbles the more load it has to bear.

Buy, Buy, Buy

SAVING is not altogether a negative virtue. It is not all scrimping self denial. Savings are the difference between income and outgo. We can save by raising income; we can save by decreasing outgo. The first is the better means. The miserly person who knows nothing but how to do without usually dies possessed of little else but greed and cunning.

So too with the nation. It is time to spend wisely on what we need, to make such purchases as will promote economical industry. The country has to meet the Fifth Liberty Loan of about $5,000,000,000. It will meet it more readily if every one is busy in the coal mines and in the factories. If we hold off to buy till the better time we shall find it will not come.

Wages are not going to be lowered even though the new scale paid to the copper men would seem to indicate that they are. The unions will keep up their high scales and the non-union men have many of them had no increases and therefore stand to receive an advance in wage rather than a decrease. Moreover there is a further good reason for holding up wages. It seems passing strange that the reason did not seem valid to the copper industry; it is a logical reason nevertheless and should be set down.

Wherever large stocks are on hand there is need to keep wages up. Otherwise it will become necessary to sell the whole product produced by high wages at a price approximating the rate at which it can be produced by low wages. The buyer will wait till the price falls to a figure based on the low wage. Thus the producer loses heavily for he has to dispose of his large accumulations of product at a figure much below the price at which he produced it.

Had he maintained wages he could have sold it at a fair margin above the cost of production. So long as wages were maintained no one would sell far below production cost but with wages cut it would be quite the best policy for the individual, who happened not to have a stock of mineral, to run his mines and sell the product at the best margin he could obtain. By reducing the wages of the miners the copper men reduced the possibility that they would be able to "break even" on the copper produced under a high wage scale.

Many will not agree with the copper men. To them a reduction in wage seemed natural, the scale being one which was arranged to slide up and down with the price of copper. True the War Industries Board thrust the price of copper down during the continuance of hostilities and the Labor Board jammed the compensating lever that made wages follow prices. But the lever has been repaired and the principle of the sliding scale has been reëstablished, unfortunate as it is. It serves the best interests of neither capital, labor, nor industry. And it will not be followed we may be sure in other lines of business.

Only a short stretch separates us from big business and a labor shortage. Immigration has been stopped for years and we have lost many men to the war. Of these, many will never come back, and there will be a hue and cry for more men.

Why delay purchasing now when a little courage for a week or two will fully justify our faith? A little buying will turn the tide and bring a flood of prosperity.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

In the anthracite region it seems likely that there will be many button strikes to coerce new arrivals from the cities to join the union, whether they will or not. The mine workers are complaining about the closing of inefficient mines. They would have the operators of the southern fields keep these plants running at a loss. As the operators are losing money on their entire investment in the southern field at present prices, the principle "All or none" pressed to its consequences will probably be answered by the operators with the single word "None." The only way to save the efficient mines is by shutting down the inefficient; that is, providing the selling price of coal is not raised.

The New River and Winding Gulf mine workers are proposing to present unreasonable wage claims. These show a desire on the part of the miner to profiteer at the expense of workmen in other industries, who will have to buy his coal and pay him his wages. The miner has many employers—absentee-employers many of them, men whom he has never seen. Some of them live in slums and some in villages. The big corporations that use his coal make goods for these people. Coal that is used for steam raising is used, not so much for the corporation which buys the coal, as for the person who uses the product of the factory. From these persons, largely not better supplied than the miner, the increases in coal price must inevitably come. A desire for excessive wages is not a sign of superiority of character, but rather evidence that the individual seeking the big pay wants something more than his appropriate share of the world's product.

Want Steady Work or Suspension

The United Mine Workers of America in the three anthracite districts will hold an important meeting at an early date. Two problems face the coal miners of this and other fields; one is the sudden halt of the coal industry, and the other is the importation of labor from the cities into the coal fields.

The Pennsylvania Coal Co. and the interests associated with that corporation recruited men in the larger cities through advertisements in the newspapers and by means of labor scouts. These men are in most cases new to the mining game. The need for their importation has apparently ended with the changed labor conditions, and now that they are here the union proposes to have them join its ranks or quit their places.

The other matter that the miners hope to consider is a plan to shut all the mines of Pennsylvania and adjoining states for a period of two weeks, to resume later for a steady run, until the market is replenished, when another suspension would be in order. The larger operators in the anthracite field in times of poor market are in the habit of closing the less profitable mines and operating those which pay best. This is notably true in the Schuylkill region. In that field the Lehigh Valley Coal Co. often suspends its Blackwood colliery for the summer season.

The Philadelphia & Reading Coal and Iron Co. follows the same plan in its Tremont-Tower City district. Labor conditions in that vicinity are peculiar to that district. They make a suspension quite feasible without loss to the company. The men are for the most part owners of small farms and are not entirely dependent on the mines for their livelihood. In winter labor is plentiful at these collieries, by reason of the cessation of farm work.

West Virginia Will Seek Higher Wages

It is learned from a reliable source that when representatives of District No. 29 of Central West Virginia met at Beckley in the latter part of January to draw up a new wage scale they formulated plans for obtaining material advances in wages.

It is said that the terms of the new scale, as drafted by the committee of District 29, call for an increase in the wages of day men of from $1 to $1.50 a day. The increase fixed for monthly men is said to run from $25 to $75 a month above the present rate. It is also understood that a minimum wage of $200 a month has been asked for what are known as company men. The demands also stipulate that there shall be an increase of 12c. a ton in the mining rate and that all overtime shall be paid for at the rate of time and a half.

The plan of the miners expressly provides that unless some agreement for a closed shop is reached, and the union is allowed to collect by check-off all dues, assessments and initiation fees through company offices, whatever these imposts may be, no contract shall be signed. The miners in the proposed agreement have incorporated a provision that all the miners of the district included in the agreement are to be paid by weight for coal mined and on the basis of a short ton. Still another point upon which the miners lay stress is that the loading of mine cars with coal shall not be limited in any way.

As having some bearing on the question of what may be finally consummated in the way of an agreement between miners and operators of District 29, the following statement of Secretary T. L. Lewis of the New River Association may be considered significant:

"It is well known that the contract between the United Mine Workers and the operators of the New River and Winding Gulf fields ends on Apr. 1. The present agreement provides that a conference be held 60 days before Apr. 1.

"The operators of both fields have always lived up to any promises made and will no doubt arrange to comply with the provisions of the agreement in the New River and Winding Gulf Districts.

"Since the wage agreements in the New River and Winding Gulf fields have passed under the jurisdiction of the United States Fuel Administration, which has made it very clear that there will be no change in the terms of the wage agreement until the official announcement has been made that the terms of the peace treaty have been signed, there is nothing to do but comply with the wishes of the Federal Government as expressed through the United States Fuel Administration.

"The coal market had during the past month or two become demoralized. The price of coal has been declining. No one can at this time foretell what the future holds in store for the coal business, but we are anxious to continue in force the present high standard of wages in our field, and we desire to say to all those interested that we shall do all we can legitimately to maintain or secure such a price for our coal as will permit of our continuing to pay such wages."

A meeting held Feb. 1 at Charleston at which the labor representatives met with the New River and Winding Gulf operators lasted only long enough for the operators to declare their position, the character of which is well covered by T. L. Lewis, the secretary, in the statement just quoted. The public is strongly against any further increases in the mine worker's wage, hence the operators of the New River and Winding Gulf regions can be assured of national support in resisting this new imposition on industry.

Be Proud of the Town You Live In

Of all ways the best way to have a tidy town is to be careful not to litter the town you have. A man from Sciacca the other day was saying how clean the City of Palermo was. There was a rubbish picker on every block who kept the streets like a clean pin. Just as he was bragging about the chief city of his island, his eye fell on a paper box and he opened the door and threw the box into the street, to be an eyesore to everybody. If the people of Palermo are all like that man they will need a rubbish picker for every hundred houses. The way to be clean is to keep clean. On windless days burn your rubbish in the backyard and keep it off the streets.

Be Tidyman of Tidytown.

DISCUSSION BY READERS

A.-C. vs. D.-C. Current in Mines

Letter No. 1—In reading the report of the Coal Mining Institute of America, regarding the meeting of that institute at Pittsburgh, Dec. 4, which appeared in *Coal Age*, Dec. 12, p. 1081, I notice that among the several vital problems relating to coal mining, discussed at that meeting, was the question, "Is the underground use of the alternating current more hazardous than the use of the direct current?"

Allow me to say that the question of the use of either of these forms of electricity, in mines, is not one that concerns their relative hazard, but regards, rather, the efficiency and purpose of the installation. It is a question whether the supplanting of one of these forms of current by the other, in any particular instance, will prove equally efficient in operation, although the hazard, in mines, by reason of men and animals coming in contact with live wires, may be lessened.

Perhaps, this discussion may have thrown some light on the practicability of adopting one or another form of current; but, in my experience, we have never used alternating current in our mines for hauling coal with any success. Also, mining practice has proved that direct current is not as well adapted for transmission as alternating current. Each of these forms of current should, therefore, be employed for the purpose for which it is best adapted, and the conductors so arranged as to invite the least hazard.

Danger of Contact with High-Voltage Wires

The voltage being equal, in each case, it is my belief there is more danger in coming in contact with a bare or poorly insulated wire transmitting alternating current, than one carrying direct current. Coming in contact with a single wire of a three-phase alternating-current system will not blow a short. I have even observed instances where contact with two wires of that system also fails to blow a short. It would, indeed, be a rare case where one would accidentally come in contact with all three wires, especially if these are properly insulated. Contact with a high voltage live wire is liable to prove fatal, unless a short is blown or someone is at hand to render assistance.

There are a number of mines that employ alternating current for the purposes of pumping and ventilation. In most cases, it has not been found necessary to carry the wires underground any great distance. Boreholes have been sunk at points on the surface directly over the points in the mine where the motor to be operated by the current is located. By this arrangement, there is little danger of anyone coming in contact with live wires and no risk is assumed by reason of employing an alternating current. The only person in any danger is the one in charge of the machinery to be operated. Anyone else would deliberately go out of his way to encounter such danger.

There are probably some mines where motors requiring to be operated by alternating current cannot be reached by boreholes from the surface. In such cases, the dangers and hazards incident to carrying the current into the mine may be minimized by employing heavily insulated conductors. Such conductors should, moreover, be kept off main haulways and travelingways, and men should be forbidden to travel where such wires are hung or to enter places where these motors are installed.

Thomas, W. Va.

Utilizing Mine Gas To Save Fuel

Letter No. 1—While I know nothing regarding the authenticity of the rumor, it is reported that one of the large operating companies in this district proposes to experiment on the question of utilizing the gas generated in its mines, by mixing the return air, charged with inflammable gas, with the air entering the fireboxes in the power plant and, possibly, adding thereto a certain percentage of elementary gas to increase the efficacy of the plant.

This report recalls the discussion that took place about a year ago, which was started by attention being drawn, in the public press, to the large loss of power resulting from the escape into the atmosphere of the great volumes of gas generated in mine workings. The idea of conserving this gas and utilizing it for the production of power was emphasized and given greater publicity through the efforts of Governor Brumbaugh, who summoned a number of engineers and coal men to a conference on the subject.

Economy Must Not Be Sought at the Sacrifice of Safety

The possibilities and dangers of the plan were freely discussed in the columns of *Coal Age* [Vol 12, p. 1029] at that time. To my mind, there is no doubt as to the economy of burning the gas that is contained in the return air of the mines and which is now wasted into the atmosphere. But, suppose the figures do show that, say a 10 per cent. saving of fuel can be effected by this means, what about the safety of injecting this gas-charged air into the firebox of a furnace?

It is a well-known fact that when pure methane is mixed with air the mixture becomes explosive, or reaches the lower explosive limit, when the proportion of gas to air is 1: 13, or the mixture contains 7.14 per cent. of gas. If dust or olefiant gas is present, the mixture is explosive when an even smaller percentage of gas is present in the air. The violence of the explosion increases with the percentage of gas present and reaches a maximum at 9.46 per cent.

How to save this great waste of gas is a difficult problem. It is one thing to suggest the possibility, but quite another thing to accomplish the fact. The piping

of methane from a strong permanent blower in a mine has been accomplished many times and the gas utilized to advantage in the development of power, but such an arrangement had no connection with the return air current, which made it safe for use. Where mining operations can be kept far enough from the source of supply of such a blower, the plan may often prove to be a paying proposition, as the pressure of the blower is not apt to be diminished by the mining of the coal.

The calculations on which the feasibility of the proposed plan to which I have referred is based are interesting. They are about as follows: Assume a forced draft of, say 1000 cu.ft. of pure air per minute is supplied to the furnaces, and compare the results with those obtained when an equal volume of return air is drawn from the Loomis Colliery, at Wilkes-Barre, Penn. A report from this colliery shows an average analysis of this return air to be: Oxygen, 20 per cent.; nitrogen, 78.93 per cent.; methane, 1 per cent.; carbon dioxide, 0.07 per cent.

Heat Generated by Combustion of Coal When Consuming 1000 Cu.Ft. of Pure Air

Let us, now, assume such a temperature and pressure that the pure air weighs 0.0765 lb. per cu.ft., which makes the weight of 1000 cu.ft. of this air, which is the assumed volume, $1000 \times 0.0765 = 76.5$ lb. Oxygen forms 23 per cent. by weight of pure air, and the weight of oxygen in this volume is therefore $76.5 \times 0.23 = 17.595$ pounds.

Again, the complete combustion of 1 lb. of carbon requires $2\frac{2}{3}$ lb. of oxygen; hence, the weight of carbon burned by the oxygen in 1000 cu.ft. of pure air is $17.595 \div 2\frac{2}{3} = 6.598$ lb. But, the heat developed by a pound of carbon burning to carbon dioxide being 14,544 B.t.u., the heat generated by the assumed supply of 1000 cu.ft. of pure air to the furnaces is $14,544 \times 6.598 = 95.961$ B.t.u.

Heat Generated When 1000 Cu.Ft. of Gas-Charged Air is Consumed in the Furnace

Now, considering 1000 cu.ft. of the return air, taken from the Loomis Colliery and containing 20 per cent. of oxygen and 1 per cent. of methane, the volume of oxygen entering the furnace is $1000 \times 0.20 = 200$ cu.ft., and that of methane $1000 \times 0.01 = 10$ cu.ft. But the specific gravity of oxygen being 1.1056 and that of methane 0.559, the weight of oxygen in 1000 cu.ft. of this return air is $200\ (1.1056 \times 0.0765) = 16.916$ lb. Likewise, the weight of methane, in the same volume of return air, is $10(0.0559 \times 0.0765) = 0.428$ pound.

But, 1 lb. of methane, in burning to carbon dioxide and water, consumes four times its weight of oxygen, which makes the weight of oxygen taken up by the methane, in this case, $4 \times 0.428 = 1.712$ lb. Therefore, this weight of oxygen must be deducted from that just found, in order to obtain the net weight of oxygen available for the consumption of the carbon in the coal, which gives $16.916 - 1.712 = 15.204$ pounds.

As before, the weight of carbon consumed by this weight of oxygen is, then, $15.204 \div 2\frac{2}{3} = 5.7015$ lb.; and the heat generated by this combustion is $5.7015 \times 14,544 = 82,923$ B.t.u. To this must be added, in this case, the heat generated by the methane burning to carbon dioxide and water, which is 23,513 B.t.u. per lb. of the gas, or a total of $0.428 \times 23,513 = 10,064$ B.t.u. The total heat generated is, therefore, $82,923 + 10,064 = 92,987$ B.t.u.

Were we to stop here, the comparison would show a loss in the total heat generated. However, it is observed that a less weight of carbon (coal) is consumed when using the gas-charged air of the return current. Hence, to complete this comparison it is necessary to estimate the heat generated, *per pound of carbon consumed in each case*, which gives the following:

Pure air, $95,961 \div 6.598 = 14,544$ B.t.u.
Return air, $92,987 \div 5.7015 = 16,309$ B.t.u.

The saving is, therefore, $16,309 - 14.544 = 1765$ B.t.u.; or, $(1765 \times 100) \div 16,309 = 10.8$ per cent.

Ferndale Explosion Caused by Gas Blower

In closing, allow me to cite an explosion that occurred when I was employed in the Ferndale colliery of South Wales, Nov. 8, 1867. The explosion was caused by the sudden breaking out of a blower that yielded a large volume of gas, which reached the furnace by which the mine was ventilated. The result was a terrible loss of life [178 lives, *Coal Age*, Vol. 9, p. 1025] and destruction of property.

The small margin between the percentage of air in the return current of a mine generating gas and the lower explosive limit of the gas appalls one with the thought of the danger of piping the return air of a mine generating gas, to the furnaces of a power plant. Any increase in the gaseous condition of the mine would undoubtedly result in a disastrous explosion that would wreck the power plant, and nothing would prevent its being carried back into the mine.

Pittston, Penn. William D. Owens.

Perils in Reconstruction

Letter No. 4—I want to voice my approval of the suggestion contained in the Foreword that appeared some time ago in *Coal Age* [Nov. 21, 1918], regarding the patriotic duties of buyers. The Foreword laid emphasis on the fact that we should not postpone purchases that are necessary, in the hope that prices would be lower in the near future. Prices will assuredly recede from the present high level, but progress in this direction will naturally be slow.

Our clearest thinkers have proven beyond a doubt that the drop in prices will be much more gradual than the rise. This opinion is based upon accurate knowledge of the situation existing in this and other countries wherever the products of American labor are transported. Truly, it behooves mine owners and managers of large industries to keep their houses in order.

Peace Problems Find Us Unprepared

We have found ourselves as unprepared for peace as we were unprepared for war, which is no discredit, but is the natural result of the sudden downfall of the enemy, following closely the vast preparation made by America to insure victory. Now, it has become necessary to throw in the reverse gears and start the work of demobilization and reconstruction in every branch of our industrial life.

While it may not be possible for every soldier to be returned to his old job, the business organization of this country is so founded that our industries will

rapidly slip back to a normal basis of production, and there will be work for all. There will, undoubtedly, be some complaining from pessimists; but real builders will give little heed to these skeptical mutterings. It is these real leaders of business—men who have devoted their lifetime to productive work on a large scale and who are clear thinkers—who achieve success in reconstruction and we must follow their lead.

Optimism of Leaders of the Coal and Steel Industries and Merchants

Speaking of the work of leaders of great industries, one can but admire such men as John Wanamaker, the merchant; Elbert Gary, the head of the steel interests; and John D. Rockefeller, Jr., representing the coal and iron industries of the West. These men stand for the highest ideals of industrial reconstruction. Without exception they have expressed themselves as being convinced that the best years of the United States lie ahead of them, and that the next five or six years will be years of unprecedented prosperity in American commerce and industry.

To be convinced of the truth of this optimism, one has but to consider the demands that will be made upon this country by reason of the devastation abroad, where rebuilding will require an enormous consumption of all materials, such as steel, cement, plaster, lumber, brick, and numerous other supplies. England and Russia will make heavy drafts on this country for years to come, which will mean a vast stimulus to our export trade and require the building and equipment, by us, of the largest merchant marine of the world.

Coal Forms the Basis of and Is Needful to All Industrial Progress

In face of these facts, it is inconceivable that industry should slacken for more than a brief period of time, which will be required for readjustment, and then every branch of manufacture and trade will regain a normal footing. Production has always been governed by the law of supply and demand—supply of coal and raw material and a market demand for the products of labor. Surely, a greater demand than the present has never existed.

Practically all production is based on coal supply. Raw materials can be worked only by the use of power, which means the consumption of enormous quantities of coal, which is the king of our natural resources. Again, the operation of mines means a large production of mine supplies, mine locomotives, cars, rails, and other requirements. While it is true these have been selling at prices prodigiously high, as have all other commodities, the present is no time to hold back on purchases of equipment and supplies that are needed for operating the mines to their fullest capacity.

There is no need, at the present time, for paying heed to the cry that "overproduction will ruin the coal business." It is my earnest conviction that there will be no overproduction of coal, in this country, for some time to come. Let us see that our plants are kept in the best possible condition that no one will be able to say the lack of coal has hindered the march of progress, which promises to give every miner steady employment for several years to come.

Philadelphia, Penn. Optimist.

Certification and Safety

Letter No. 1—In the report of the recent annual meeting of the Coal Mining Institute of America, appearing in *Coal Age*, Dec. 12, p. 1080, the fourth question discussed interested me most. It reads as follows: "Has the law permitting the employment of noncertified officials, in coal mines, been detrimental to their (the mines) efficient and safe operation?"

As might be expected, the discussion developed a strong difference of opinion among those present. The report states that while some claimed that the amended law has produced no effect, in the anthracite field, other than to cause the employment of uncertified men to fill positions formerly open only to men holding certificates, others who took part in the discussion claimed quite the contrary. In one case, a speaker stated that 28 men, holding no certificates, were employed in one inspection district that showed an increase of accidents largely due to that cause.

What appeals to me, in this connection, is that an intelligent body of men, meeting to discuss questions of vital interest to their calling, should not arrive at some definite conclusion. In this instance, as far as gaining any accurate knowledge of the situation and adopting some form of remedial resolution, the question might just as well never have been brought to the notice of the meeting. To my mind, a great boon to the mining industry would result had the discussion of members been confined to fewer subjects and each subject been dealt with more fully, whereby practical conclusions could have been reached. That is what mining men desire.

While I admit, as was remarked at the meeting, that "a certificate is not a guarantee of competency," I claim that a man without a certificate cannot be classed as competent, in respect to present-day requirements when so much depends on the technical knowledge of men holding responsible positions in coal mining.

Different Estimates of Competent Foremen

A man of practical mining experience, who possesses, besides, sufficient technical knowledge to enable him to pass an examination before the state mining board, is far more competent than one who has the same practical experience but possesses no technical knowledge. On the other hand, a man who has all the book knowledge it is possible for him to get, but possesses little practical experience in mining, is unfitted to fill any responsible position in the operation of a mine, and particularly the work underground.

Coal operators are apt to consider that the man who can get out the most coal at the least expense is the most competent man, whether or not he holds a certificate. Let me ask such operators if they are sure such a standard of competency will guarantee the future welfare of their properties. Do they realize that their mines are being worked in a haphazard manner, instead of being operated according to a scientific principle? In the former case, the responsible party sooner or later sees "the writing on the wall" and gives up his job before the results of his incompetency become too plainly evident to his employers.

The difficulties that are sure to follow and reveal a ruined mine are left for his successor to handle and

solve as he may. Many a good man, succeeding to a position in a mine that has been mismanaged, realizes as no one else does that the man before him gained his reputation for competency, at the cost of the mine.

A hard uphill struggle with high costs faces the newcomer, and it is not strange that this one is too frequently regarded by his employer as being less competent than the man before him. It does not occur to the management that the man they had formerly trusted has wrecked the mine and made it impossible for the new man to produce results. True it is, as one speaker stated, that "operators are not always competent to judge the qualifications of the foremen."

As well may it be argued that there is no need for the certification, by examination, of our state mine inspectors, as to disclaim the need of the same for men seeking the position of mine foreman. Both of these officials have the same problems to handle with respect to the safety of the mine and the men employed therein, and each has the same need of both practical and technical experience and knowledge if we are to avoid dangers of mining, secure the economical extraction of the coal and conserve our natural resources.

Brief Review of Coal-Mining Legislation

Allow me, in closing, to refer to the report of the Avondale (Penn.) disaster of Sept. 6, 1869, when an anthracite breaker, located over the mouth of a shaft, where there was but one opening, caught fire and was burned, with the result that 108 men at work in the mine were asphyxiated.

As is well known, this terrible disaster caused the Pennsylvania legislature to pass the first general law ever enacted in the United States, providing for the regulation and inspection of anthracite mines, Mar. 3, 1870. A similar law was enacted for bituminous mines, in Pennsylvania, in 1877; and, in 1885, the law was passed requiring the certification of mine foremen and assistant foremen.

In my opinion, if it was necessary, in 1885, to employ certified foremen in mines, in order to reduce the number of accidents therein, it surely must be expedient to require the same method of certification of these officials, at the present time, not only in Pennsylvania, but in every coal-producing state.

This is made more imperative by the use of electricity and compressed air for driving much complicated machinery and equipment requiring mechanical skill and technical knowledge for its operation. I hope to see this subject thoroughly discussed in *Coal Age*, whose readers are able to weigh intelligently the pros and cons and decide the necessity or otherwise of certified mine foremen. James Touhey.

Vancouver, B. C., Canada.

Hindrances to Coal Production

Letter No. 9—In the recent discussion of the many hindrances to the production of coal, mention has been made of almost every conceivable thing, as intemperance, poor or inadequate equipment, undesirable living or social conditions, etc.

It is readily granted that all of these play their part in contributing, more or less, to the minimizing of coal production. I read with interest the suggestions made for eliminating these different causes and believe that, with the right management of a mine, many of them can be counteracted.

If my memory serves me correctly, however, mention has not been made of one important hindrance to mine work. I refer to the celebration, by foreign miners, of their many holidays. To my knowledge, there has never been any stirring impulse among this class of miners to overcome this hindrance to the work. Even the war has not provided the patriotic stimulus required to induce the foreign miner to refrain from these celebrations and continue his work in the mine. It is difficult to estimate the loss in tonnage due to this cause alone during the war, and it is probable that the same will still continue to reduce the output of our mines and hamper the industry.

Plan to Compensate for Foreigners' Holidays

One plan that I have seen tried in overcoming this difficulty and avoiding a part of the loss in production is to operate the mine till midnight, preceding a foreign holiday. Where it is practicable to dump coal after nightfall, this suggestion will generally be found valuable. During the war, some of the mines adopted this plan and found that the majority of the men were willing to work through till midnight, preceding a holiday. It gave them an opportunity of making a fair day's wages, without violating the spirit of the particular feast or holiday, which they were all anxious to observe after their own method and custom.

In my own experience, I have found little or no difficulty in getting the large majority of our men to work a double shift in view of the holiday, which would give them an opportunity to rest. In my canvass of the mine, I have found that, unless this plan was adopted, nearly all of my men would be absent the following day.

Thomas, W. Va. Foreman.

[This letter will close the discussion on "Hindrances to Coal Production."—Editor.]

Perplexities of Mine Foremen

Letter No. 11—The letters relating to the problems confronting a mine foreman—the man who comes directly in touch with each individual employed in the mine—have interested me greatly and I want to draw attention to one point that, in my opinion, is one of the most difficult situations a foreman is ever compelled to face.

There is a certain class of miners who may be properly described by the term "suckers." These fellows, instead of taking their complaints directly to the foreman, have a habit of going over the foreman's head and telling their grievances to the superintendent. I am sorry to say that one will frequently find a superintendent who is silly enough to listen to such miners, instead of telling them to see their foreman. The miner who will do this trick is usually a chronic kicker, and goes to the superintendent, whom he believes is not acquainted with his ways and will give his little matters more attention than he could hope to receive from the foreman, who knows him better.

A superintendent who is wise will promptly refer all such complaints to the foreman, who is in direct charge of the men. Failure to do this not only displays a

disposition on the part of the superintendent to distrust his foreman, but is also liable to arouse feeling among the employees, who are led to think that the foreman is not the one that will give them the most satisfaction. In other words, the foreman loses prestige with the men and his influence over them is lessened.

Every good foreman must be capable of divining correctly the disposition of each individual he employs and dealing with them as individuals. Some men are much easier to handle than others. While some are interested in the welfare of the company, others seek every opportunity to enrich themselves at their employer's expense. Some men are neat and accurate in their work, while others are dilatory and wasteful, desiring to get the most pay for as little work as possible.

Foremen Require Tact in Treatment of Men

A foreman must be able to treat these different dispositions of his men with tact. He must be firm in respect to seeing that his orders are strictly obeyed. He must avoid letting his men feel that he is socially above them, and show that he is interested in their welfare. His instructions must always be along practical lines.

While it is natural for a foreman to think more of a man who shows an interest in his work, he must manifest no favoritism and have no "pets." He must listen to all complaints that are seriously made and not be hasty in pronouncing judgment before he has thoroughly investigated all claims. It is a foreman's duty to adjust a matter in the most economical way, conferring with his superintendent whenever this may be necessary, as it will show the disposition of the foreman to do what is right, and will impress both the superintendent and the miner whose claim he is trying to adjust. Such action will go far toward preventing miners from taking their grievances to the superintendent, as it will increase the confidence of the men in the ability and fairness of the boss. I. T. C.

Oliver Springs, Tenn.

Letter No. 12—It is my belief that a good mine foreman will meet with a great many perplexing problems. I fail to see how he can escape them, because they are present in all coal mines. An indifferent foreman may not meet with the same difficulties as one who is more painstaking and careful, because he does not attempt to improve conditions but allows many matters to take their own course.

Now that the war is over, the suggestion of applying martial law to enforce miners to work the full 8-hour shift, which was made by R. W. Lightburn, *Coal Age*, Dec. 5, p. 1047, does not call for consideration. Certainly, it is aggravating when a loader cannot get the cars he needs to load his coal, or having the cars finds that his coal is not cut because a driver or a machinerunner is satisfied with 4 or 5 hours' work instead of remaining at his post throughout the shift.

It appears to me that there should be an effective remedy to apply in such cases. If such independence of workers results from their knowledge of a scarcity of men to fill their places, attention should be given at once, by mine officials, to the training of more men for that work. Men often become dissatisfied with their particular work, for little or no reason.

A machinerunner may regard his work as more hazardous than that of the loader, or think that because of the dust he is entitled to work shorter time, or there may be a consciousness of his own skill and importance that gives him an overbearing and selfish disposition and leads him to disregard the interests of others and consider solely his own convenience.

Speaking of complaints, if a mine foreman took these as seriously as they are usually made to appear he would be run to death in short order. The fact that a foreman turning a deaf ear to the complaint of a miner regarding the condition of his place causes the miner to light his pipe and start for home is no proof that the foreman made a mistake in not going at once to look at the place and satisfy the miner.

Nine times out of ten the foreman knows that the miner himself is to blame and, further, that he is only seeking an excuse to get out of the mine, and there is no great loss in his going. To my mind, there is no cause for a foreman to get excited in such a case. Let him jolly the man along, remembering that more will be accomplished by tact and method than by an angry word that can only arouse hatred.

Daily Visits to Working Places Required

In West Virginia, the law requires a mine foreman or his assistant to visit every working place, at least once a day, while the miner is at work. When this is done the knowledge of the foreman as to the condition of a miner's place is equal to that of the miner himself, unless there has suddenly developed a bad slip in the roof, a fall of slate, a gas feeder, or other unexpected trouble. In any case, the foreman can remain cool and advise the miner to work in another place until he gets around. He knows that there are other matters of equal importance, which are urgent, and all must take their proper turn.

A foreman should make it a rule to anticipate most of these complaints and, if possible, prevent many of them from being made, by seeing that every working place is safe for work and has a plentiful supply of timber and tracking. Where water is liable to accumulate, attention should be given to draining the place and making it fit for work.

Good Foremen Keep Men from Going Home

A good foreman will not let any man go home when it is a possible thing to adjust his difficulty and keep him at work. It will sometimes happen that roadmen have not laid the switch necessary to enable a car to be taken into a place; or a fall may have occurred in that section, which prevents them from getting the needed cars. But, while these matters are being adjusted, there is generally something that a mine foreman can give men to employ them profitably, until they can return to their place.

In general, let me say it is not creditable to a foreman's ability to allow good men to go home because of some little delay in getting their place in readiness for them to work. If men go home, with an able foreman in charge, it is because of their unwillingness to work and their desire to get out of the mine.

Thomas, W. Va. W. H. Noone.

[This letter will close the discussion of "Perplexities of Mine Foremen."—Editor.]

INQUIRIES OF GENERAL INTEREST

Piping Mine Gas to the Surface

Kindly answer the following question: In a mine generating large quantities of gas, a fire started in No. 4 room on the second south entry, at a distance of 1000 ft. from the main shaft. The fire gained such headway that it was thought advisable to seal the mine, which was done.

When this had been done, a 3-in. hole was drilled from the surface into the room where the fire was located, the purpose being to drain off the gas, which was at its most explosive point. I want to ask if this gas was lighted at the top of the pipe would it explode the mine? Is there any record of such an occurrence?

Francisco, Ind. HARMON KELLEY.

Assuming that the gas-charged air issuing from the pipe is a firedamp mixture of explosive proportions, as stated, its ignition at the top of the pipe would be promptly followed by an explosion of the same mixture accumulated in the mine. A feeder of pure gas piped to the surface would burn quietly without explosion, as is the case in numerous instances where it is desired to drain the gas from the measures. We know of no recorded instance of a mine being exploded from this cause.

Lubricating Mine Cars

Kindly permit me to ask for an expression of opinion from mining men as to the cost of lubricating mine cars equipped with the average type of plain-bearing wheels. Can anyone answer this question by giving definite facts and figures? While some advocate the use of "blackstrap" once a day, or every time the car comes to the tipple, others claim it is necessary to oil the cars, say four times a week, and still others say that once a week is sufficient.

It is stated by some that a half-pint of oil should be squirted into a wheel of the self-oiling type of plain bearing, at one time. In many cases, a quart more or less, of oil is poured into or squirted at or on the wheel every time it is oiled. As an illustration of this, the incident recorded by a writer who observed the oiling of car wheels at an Alabama mine, *Coal Age*, Jan. 30, p. 246, is of interest.

From the best obtainable information, the average mine practice, regarding the oiling of plain-bearing car wheels, is to apply the oil every time a car comes to the tipple or to the shaft bottom, when about a half-pint of black oil is used on each wheel. Now, if that is the case, the waste of lubricating oil on such cars must amount to an enormous figure, in the course of a year.

Suppose, for example, that the average turn of cars, in mines, is about two and one-half times a day. Where this is the case, each car, perhaps, consumes about five pints of oil per day; and, counting 280 working days per year, this would amount to 175 gal. a year. The cost of black oil ranges from 12 to 15c. per gal. Estimating at the lower figure, the cost for lubricating a single car equipped with plain bearings would be $175 \times 0.12 = \$21$. Even allowing that this estimated amount is twice too large, the cost of lubricating would be $10.50 per car per year, which is no inconsiderable item on the mine cost-sheet.

Only recently, I saw it stated that cars equipped with roller bearings required to be lubricated but once in from three to six months, when only one pound of grease or less is applied to each wheel. Assuming, for sake of comparison, that these cars are lubricated every three months, 16 pounds of grease would be required, per car, per year, at a cost of 10c. per pound, making the total cost for lubricant, $1.60, per car, per year. This shows a difference in the cost of lubricant for plain-bearing, as compared with roller-bearing cars, taking the lowest estimate in each case, $10.50 — $1.60 = $8.90, per car, per year. Where a mine has 500 cars in daily use, this would represent a saving of $4450 per year.

In this comparison, the larger estimate appears to be too great, while the smaller one would seem too small in considering that 75 per cent. of the black oil applied to plain bearing cars, in the ordinary mine, leaks out or, perhaps, never reaches the bearing at all, but is wasted in its application.

The estimated costs just given is for lubricant only and does not include the labor required for its application. When plain-bearing cars are used the oiler must be constantly on hand, and the cost of labor for lubricating, say 500 cars, would amount to about $8 per day, or $2240 per year.

On the other hand, when mine cars are equipped with roller bearings their lubrication will require the labor of one man 40 days a year, at $4 per day, or a total of $160 per year, showing a saving in favor of the latter type of cars of $2080 per year. If this estimate is taken as being approximately correct the entire saving for lubrication, in the use of roller-bearing cars, is $6530 per year, in a mine where 500 such cars are in use.

As this sum represents a liberal rate of interest on a considerable amount of money, it would be of interest to hear from any who have kept an accurate account of these costs, in the lubrication of either plain-bearing or roller-bearing cars. OBSERVER.

Philadelphia, Penn.

It is to be hoped that this inquiry, regarding the cost of lubricating plain-bearing and roller-bearing cars, and the request for figures representing actual costs in practice, will be responded to by the readers of *Coal Age*, who are invited to give the results of their observations and experience. The subject is worthy of careful consideration, as is clearly shown in the estimated costs given in the inquiry.

EXAMINATION QUESTIONS

Mine Managers' Examination, Springfield, Ill., Dec. 17, 1918

(*Selected Questions*)

Ques.—Suppose that in a gassy mine the quantity of air passing is 175,000 cu.ft. per min., measured in the return airway and containing 4 per cent. of firedamp, when the barometer is 30 in. (a) What quantity of firedamp is given off in the mine? (b) What is the least decrease of the quantity of air that will render the return air explosive? (c) What increase of gas will render the return air explosive?

Ans.—In this question, the words *marsh gas* should be used in place of "firedamp," when speaking of the gas given off and which forms firedamp only when mixed with air in inflammable or explosive proportions. (a) The quantity of gas given off in this mine is 175,000 × 0.04 = 7000 cu.ft. per min. (b) Taking the lower explosive limit of marsh gas and air as reached when the proportion of gas to air is 1:13, or the gas forms 1/14 of the firedamp mixture, the total volume of air and gas, in the return current, when the explosive point is first reached is 14 × 7000 = 98,000 cu.ft. per min. Hence, the decrease in the quantity of air passing to form this condition is 175,000 — 98,000 = 77,000 cu.ft. per minute. (c) The quantity of air passing before any change is made is 175,000 — 7000 = 168,000 cu.ft. per min. The quantity of gas required to bring this volume of air to its lowest explosive limit is 168,000 ÷ 13 = 12,923 cu.ft. per min. To form this condition in the return airway would require an increase in the quantity of gas given off in the mine equal to 12,923 — 7000 = 5923 cu.ft. per minute.

Ques.—A borehole from the surface is 6 in. in diameter and enters the old workings of a mine. A mixture consisting of 50 per cent. of marsh gas (CH_4) and 50 per cent. of the air is passing up this hole, with a velocity of 130 ft. per min. (a) What is the volume of the flow in cubic feet per minute? (b) What would be its volume if sufficient air were added to bring the mixture up to the highest explosive point?

Ans.—(a) The diameter of this pipe being 6 in. (½ft.) its sectional area is $0.7854(\frac{1}{2})^2 = 0.1963$ sq.ft. For a velocity of 130 ft. per min., the volume of air passing is 130 × 0.1963 = 25.519 cu.ft. per minute.

(b) This being a 50 per cent. mixture of gas and air, the quantity of gas passing up the pipe is one-half the flow or 12.7595 cu.ft. per min. The maximum explosive point of pure marsh gas and air is reached when the mixture contains 9.46 per cent. of gas. The volume of the flow when at this point would therefore be 12.7595 ÷ 0.0946 = 134.88 cu.ft. per minute.

Ques.—How would you proceed to clear a shaft that is filled nearly to the top with carbon dioxide?

Ans.—There are several means that can be adopted to clear out this gas, depending on the equipment at hand. Probably the simplest and most effective method to employ is to bail out the gas, which is much heavier than air, and often difficult to remove in any other way, because it sinks to the shaft bottom owing to its greater density. However, the arrangement must be such at the top of the shaft that the gas will be prevented from flowing back into the shaft when emptied from the bailing bucket.

Where it is possible to utilize the current from a powerful blower or ventilating fan, the gas may be removed by blowing air into the shaft through a flexible canvas tubing, say 12 or 14 in. in diameter. The tubing should be gradually lowered into the shaft as the heavy gas is removed. Or it can be lowered at once to the shaft bottom, provided the air current is strong enough to expel the gas.

Ques.—(a) How is electric current generated before it is transmitted? (b) How is the transmitted electric power utilized?

Ans.—(a) An electric current is generated by the operation of a dynamo driven by a steam engine or other source of mechanical power. The dynamo is then called a *generator.*

(b) The transmitted electric power is utilized by passing the current through a dynamo, which is then called a *motor.*

In the first instance, the revolution of the armature of the dynamo is caused by the power applied to the crank shaft or belt-wheel of the machine. The armature, being thus revolved in the magnetic field of the dynamo, generates an electric current, which makes this machine a *generator.*

In the second instance, the electric current passing through the armature of the dynamo causes it to revolve, by reason of the reaction of the magnetic field of the dynamo on the armature, thus making the machine a *motor* capable of driving other machinery.

Ques.—There is a shaft 50 ft. deep in a hillside, and 500 ft. away is a creek, which is 100 ft. below the level of the bottom of the shaft. Is it possible to drain the water from this shaft into the creek, with a siphon? Explain how this can be done.

Ans.—The theoretical limit a siphon will lift water, or the vertical height of the crown of the siphon above the water in the sump, is 34 ft., at sea level. Allowing, however, for the friction of the flow in the pipe, this theoretical height or lift of a siphon is reduced in actual practice and will not much exceed 28 ft. at sea level, much depending on the length of the siphon, from the suction to the discharge end of the pipe.

The depth of the shaft in this case being 50 ft., it will not be possible to lift the water to the top of the shaft by means of a siphon. In order to drain the water from this shaft by a siphon, it will be necessary to tunnel into the shaft at a height not exceeding 28 ft. above the shaft bottom, assuming a sea-level location.

FOREIGN MARKETS AND EXPORT NEWS

Must Increase Imports to Become An Export Nation

If the United States ever is to rank as the leading exporting nation of the world it must become a greater importing nation than it now is. The foreign trade built up by England during the last decade shows that coal looms as a large factor. This is not so much because her coal fields are near to the European consuming markets (witness the long oversea trips made by her coal-carrying vessels to South American and other ports), but is due to the fact that an outgoing coal freighter from a British port can be considered as a vessel sailing in ballast. The return cargoes in great measure help pay the freight.

Only in extreme cases can a freighter carry coal to a certain destination and return to its home port without a cargo, and where this is done the coal is exorbitantly high in price. It is not the way in which the business is carried on as a general rule. Coal is an exceedingly bulky commodity, and the only manner in which it can be handled conveniently is in bulk. As a consequence, in order for the United States to carry on a successful export business in coal, it must be evident that we must import an equal quantity of bulky material before real economy in transport can be enjoyed.

Of course, what has been said in the foregoing is not the only consideration, though it can well be stated to be the chief one. Other elements that enter into the competitive ability of coals are the physical and chemical qualities, and the cost of placing the cargo aboard ship.

So far as production is concerned the United States easily leads the world in the actual tonnage mined, with England and Germany following. From analyses it would appear that the coals of the Northeastern field of England resemble rather closely coals from our Pennsylvania, Ohio and the Kanawha and Thacker fields of West Virginia; while the Welsh steam coals seem to prove up a little better chemically than our New River and Pocahontas coals. The Welsh anthracites are practically identical to our Pennsylvania anthracite.

In the past the drawbacks to the introduction of American coal in foreign markets were its size, its disintegrating nature and its high cost. Steam coal on reaching destination abroad should be at least 70 per cent. large lumps and pieces, but exports of American coals in recent years have not been maintaining that average. On the other hand, the maximum degradation in a cargo of English coal will not exceed 20 per cent.

Italian Coal Trade

From an authoritative source it is stated that the opposition in Italy to the proposed State monopoly for the sale of coal is growing. The idea was formed for the primary object of increasing the revenue, but it is recognized that this can only be accomplished by the State charging consumers higher prices than could be secured under the old regime. Therefore, the industries of Italy would be placed under a disadvantage compared with other importing countries in respect of the cost of coal. It is felt that the measure would restrict the export manufacturing trade of the country, and for this reason the opposition toward a State monopoly of the coal trade is growing.

Port Facilities of Vigo

Vigo is a city of about 50,000 inhabitants and is one of the most important ports of Spain for emigrant traffic. Before the war as many as 80 trans-Atlantic steamers called in a single month taking thousands of emigrants, principally to Cuba and South American ports. The present port works are insufficient to accommodate the larger vessels, which usually lie off the piers.

There are three piers at Vigo, the largest being little used at present, due to the fact it was defectively constructed. There is also a pier for passengers, which is built of stone and iron and railway cars run on it. It also has a crane with a lifting capacity of 20 tons. The wharf which is principally used, but only by small boats and lighters, is known as the "Commercial" pier, and it has a movable steam crane with a lifting capacity of five tons, besides two hand cranes.

All lighterage is done by a sociedad or combination of lighter owners. There are about 50 lighters available for regular use and they can accommodate 500 to 600 tons each. There are about 20 tugs usually employed for steamers, but their number can be increased if necessary, by hiring some of the hundred odd fishing tugs to be found there. Coal bunkering is done alongside coal hulks and from lighters in the roadstead. Three coal hulks are now available. At present only Spanish coal is procurable, and it costs $34.74 per ton. Before the war Cardiff coal was kept in deposits at Vigo, and it is probable that this will again be the case.

Stevedoring is done by natives, both men and women, who receive 7 pesetas (1 peseta equals $0.193) per eight-hour day. Overtime is paid at the rate of 1 peseta per hour if by day, or 1.50 pesetas if by night. Foremen receive double pay. The mean rate for stevedoring is 1.75 pesetas per ton or cubic meter. Steamers can be loaded or unloaded at the rate of 100 tons per hour.

Loading or discharging coal by the bridge or on the quay costs 1.25 pesetas per ton, but stowing in bunkers is paid for separately at 7 pesetas per man per eight-hour day. Loading or discharging coal from lighters or coal hulks costs 1 peseta per ton, but the price is doubled if there are no winches. As a basis for the cost of handling coal at Vigo it may be noted that the Spanish railway pays 2.25 pesetas per ton for discharging Spanish coal from railway cars onto the quay, where it is kept in deposits and then loaded on steamers as required. To this must be added the usual cost for stowing in bunkers, as stated above. Coal can be delivered at the rate of 100 to 120 tons per hour.

The Spanish press has recently been publishing articles concerning an alleged project of American financiers to build a direct railroad line from Vigo to Irun on the Franco-Spanish frontier and to run steamers from New York to Vigo. The advantage of this port arises from its geographical position which permits the distance for ocean travel between Europe and the United States to be considerably shortened. This is best shown by the following comparison of distances between New York and various European ports.

England's Coal Trade in 1918

In taking a general survey of the coal trade in the United Kingdom during the year that has just come to an end, says the *Colliery Guardian*, Jan. 3, 1919, it is necessary to keep in view the fact that the year 1918 has been one of the most critical epochs of British history.

Production, of course, has suffered, and the output for the year, when the full figures are available, will show a considerable deficiency, even when compared with the reduced production of 1917. From the figures published by the Coal Controller for the 10 months ending Oct. 12 last, the total deficiency up to that date was 16,490,500 tons, or about 8.4 per cent. The cause of this decline in output is mainly to be attributed to the steady depletion of manpower brought about by the combing-out of the younger miners, in consequence of the urgent demand for men. The withdrawal from the mines of 50,000 of the best workers could not have resulted in anything else but a loss of approximately 1,000,000 tons of coal per month. But other causes have also contributed their share of the deficiency, and among them perhaps one of the most potent has been the irregular supply of tonnage, which in some cases, particularly in South Wales, was responsible at times for irregular working at the collieries. In the early part of the year this irregularity was the subject of a special inquiry by the Coal Controller, when serious efforts were made to find a remedy. The most favored suggestion, at the time, was a scheme for a more uniform distribution of the available business by apportioning orders, through the medium of the local coal committees, among the collieries in a position to execute them.

Such a scheme, however, would scarcely alleviate all the difficulties surrounding the transport question. Not only has the tonnage shortage aggravated the position in the exporting districts, but even in the case of inland trade the movement of coal has been attended with difficulty. The Coal Controller's scheme for inland distribution was not an unqualified success, and has caused a certain amount of dissatisfaction in some districts. Neither have coal owners been altogether satisfied with the pooling arrangements for cars, for, upon the whole, it is questioned whether the mobility of the car supply has been sensibly increased by this means. With regard to tonnage deficiency, the effect has been unequal. Thus while shipments from Glasgow and the western ports were only a little below prewar figures, those from Fife and the Forth have been seriously reduced, partly because less tonnage was available on the east coast, and partly because the ports of Bolness, Grangemouth, Granton and Burntisland have been largely taken over by the Admiralty.

The difficulties of coal distribution have been materially simplified since the armistice, and the Coal Controller has been able to issue fresh instructions to collieries and dealers, with a view to improving the supply of house coals, of which the delivery, except, perhaps, in the London area, has threatened to be rather short. To this end, collieries have been told to send, for household purposes, both manufacturing and steam coals as an emergency measure, which is rendered posible by the reduced demand for munition purposes. It is doubtful, however, whether such a diversion of manufacturing fuel can be effected without endangering the reserves at work. Some industries have not been any too well supplied all the year. Thus, the pottery trade was rationed to 75 per cent. of the 1916 supply, but has not been able to secure even this reduced amount. Similar restrictions in fuel supply have been felt in other industries, especially those not directly concerned with munitions; and it is clear that the country has been very near to a coal crisis, the escape from which may be fairly attributed to the skill with which Sir Guy Calthrop has dealt with a very delicate situation. Naturally, his methods have been severely criticized, but the fact remains that thus far the deficiency of output has been so manipulated that nobody can yet very seriously complain.

As far as prices are concerned, these have maintained a high level, at which they seem likely to remain for some considerable time. War-wage increases have been followed by successive rises in the limitation price of coal. The exporting collieries, also, have had their particular grievance removed by the abolition of the unequal treatment of export coal to France and Italy. Any advantage, however, which might have accrued to the coal owners from these increases has been checked by the terms of the Coal Mines Control Agreement (Confirmation) Act, which passed through Parliament in the early part of the year. Under this Act the colliery owners have to surrender 95 per cent. of any excess profits, 15 per cent. of which goes to the Controller's guarantee fund. Possibly a more serious result of this Act, however, is the restriction which it has entailed upon the internal economy of coal mine management. It is true that the effect has lately been somewhat relaxed, but it has operated as a check upon development.

Details of the coal export trade of the United Kingdom for the 11-month periods ending Nov. 30, 1917 and 1918, as supplied by Consul General Skinner, appear in the following table:

To	1917 Tons	1917 Value	1918 Tons	1918 Value
Sweden	553,082	3,775,171	997,945	9,078,747
Norway	967,395	6,435,357	1,187,510	11,319,761
Denmark	778,816	5,155,302	973,940	8,812,020
France	16,495,565	102,579,504	15,314,128	106,848,451
Italy	3,789,909	24,427,441	3,778,930	26,287,315
Gibraltar	1,102,886	7,248,803	1,508,654	10,962,599
Malta	1,601,425	11,406,600	1,112,919	8,097,598
Egypt	1,448,459	9,707,153	1,620,524	11,679,960
Totals	32,801,977	$211,503,367	29,660,615	$216,815,982

Coal Situation in Canada

The unusually mild weather this winter has saved the coal situation in Canada. Fuel conditions are now easier there than they have been for months past, owing to the absence of severe weather. The mild weather prevalent in the United States has also reached Canada, and as a result coal has been going across the border in steady quantities.

Bunker Coal Shipments from United Kingdom in December

The quantity of bunker coals shipped on vessels engaged in the coastwise trade during December last from the United Kingdom amounted to 84,602 tons. Of this total only 7398 tons were bunkered at Bristol Channel ports, while 31,176 tons were shipped at the Northwestern ports, 15,744 at the Northeastern ports, and 14,208 tons from the West Coast of Scotland. The coastwise trade in coal for the same month totaled 730,359 tons, of which 104,625 tons were shipped from the Bristol Channel ports, 159,687 tons from the West Coast of Scotland, 103,553 tons from the Northwestern ports, and 314,300 tons from the Northeast Coast.

Foreign Freight Rates

W. W. Battie & Co.'s coal trade freight report for Feb. 17:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge.

Sail (maximum) — Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net; Santos, $19.50 net; Buenos Aires, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. (Gross rates $1.50 per ton in excess of net rates). On all the foregoing rates, charterers pay vessel's towage to coal port. To Nitrate Range, $16.50 gross prepaid. (Same rate steam.)

The Chartering Committee's rate by steam is $19.50 net to Rio or Santos, $18.50 net to Buenos Aires and $19.50 net to Montevideo.

Leading exporters of American coal have established committees through the National Coal Association to appeal to the Shipping Board to increase tonnage available for carrying coal to Central and South America.

COAL AND COKE NEWS

Harrisburg, Penn.

A bill introduced into the House by Representative Sinclair of Fayette County, provides that it shall be lawful for all incorporated or unincorporated churches, cemetery companies and burial associations now prevented by charter restrictions or otherwise from leasing or selling coal or other minerals owned by them, to sell, lease or convey the mineral, subject to such conditions as will insure the support of the overlying surface and subject also to the requirements that at least 50 per cent. of the coal and other minerals be left in place, properly distributed to support the surface, and that no mining be done or permitted closer to the surface than 200 ft. The bill further provides that the funds derived from the sale of the coal be used for the purchase of additional land, or for the improvement, beautifying, endowment and maintenance of the properties.

Deputy Attorney General Swoope has rendered an opinion arising in the Game and Fisheries Department, in which he informs the Commissioner of Fisheries that he should first notify mining companies charged with the polluting of streams to stop, and if they refuse evidence should be secured for prosecution.

A State Commission to investigate the possibility of making the Susquehanna River navigable is provided by a bill introduced into the House by Representative Hess, who for many years has been Chairman of the House Committee on Mines. The Commission is to be allowed $5000 for expenses, but the members are to receive no compensation. A consulting engineer is to be named. The bill attracted much attention among legislators as there has been much discussion of the project, as it is contended that the making of the river navigable would reduce the cost of coal, as the river runs through the heart of the anthracite region and through part of the bituminous coal fields.

Uniontown, Penn.

Within the past three weeks the Connellsville coke region has undergone a rapid and orderly readjustment to comply with immediate post-war requirements that is considered no less remarkable than was its quick mobilization for war under the regional fuel administration. From an industry brought together under indirect control and keyed to the highest point of maximum efficiency, the Connellsville coke region has been returned to its own resources and is now proceeding at a rather leisurely gait in order to get its breath for the boom believed assured when the iron and steel reconstruction period gets under way.

When Government restrictions were lifted Feb. 1 the average weekly production was 650,000 tons (coal). It has steadily declined at the rate of 40,000 tons (coal) weekly by an effective curtailment policy made necessary by the closing down of a number of blast-furnace operations. There is every indication that production in the immediate future will anchor around 525,000 tons (coal) weekly, with coke at 225,000 tons. Close observers believe that the bottom in curtailment was reached this week and that until there are more encouraging developments in the industry it will become stabilized at 525,000 tons (coal) weekly.

Limited employment for everybody and no reduction in shifts is the policy adopted by operators to prevent an unemployment problem in the coke region. All plants generally are working on a four- and five-day basis, the H. C. Frick Coke Co. this week suspending operations for a day at a number of plants. Heretofore the corporation plants had been working six days but had eliminated extra shifts, but independent operators have been observing lay-off days for a month or more. There has been no general revision of present high wage scales and none is contemplated. One small operation, the Harah Coal and Coke Co., this week gave its men the choice of accepting a 30 per cent. wage reduction or closing down the plant. They accepted the reduction.

Pittsburgh, Penn.

It is being persistently rumored in and around Pittsburgh that plans are under way for a merger of the Hecla Coal and Coke Co. and the United Coal Corporation, both Pittsburgh concerns and in both of which J. H. Hillman, Jr., of Pittsburgh, is the majority stockholder, being president of the former and a director in the latter.

The Hecla Coal and Coke Co. operates several mines and coke-oven plants in Fayette County, in the Connellsville coke region. The United Coal Corporation operates mines in Allegheny, Westmoreland, Fayette and Somerset Counties, and through its subsidiary, the Merchants Coal Corporation, the Tunnelton mine at Tunnelton, Preston County, West Virginia.

Rumor also has it that part of the official family of the new corporation will be constituted as follows: J. H. Hillman, Jr., president of the Hecla Coal and Coke Co., to be chairman of the board; Tracy W. Guthier, president of the United Coal Corporation, to be president; William L. Affelder, general manager of the Hecla Coal and Coke Co., to be general manager; and Harrison T. Booker, general superintendent of the United Coal Corporation, to be general superintendent.

The Hecla Coal and Coke Co. was organized a couple of years ago by a merger of the Bessemer Coke Co., the Isabella Connellsville Coal and Coke Co. (at one time a subsidiary of the United Coal Co. and acquired during the United receivership by the Hillman interests) and other smaller Hillman interests.

The United Coal Corporation was founded July 1, 1916, by the reorganization of the United Coal Co. and its subsidiaries, the Naomi Coal Co., the Pittsburgh & Baltimore Coal Co. and the Jenner Quemahoning Coal Co., which had been in receivers' hands since 1913. On July 1, 1917, it acquired a majority of the bonds of the Merchants Coal Co., another subsidiary of the old United, and took those properties over from the receivers and organized the Merchants Coal Corporation, since operated as a subsidiary company.

Charleston, W. Va.

Much idleness among miners prevails in the Fairmont district as a result of numerous suspensions of operations following a slump in the market, the number of idle miners on one division of the Baltimore & Ohio being between 150 and 175. This is due not solely to a lifeless market but to the policy of railroads not to purchase coal except at excessively low prices. The same conditions prevail through the district. The car supply for the Fairmont region is far in excess of the loading and shipment of such cars. An average of 3000 cars a day is still being supplied to the mines. Loadings average anywhere from 500 to 800 cars a day, with a small percentage of such cars moving westward. Since Feb. 1 some of the larger companies in the district have suspended operations until general conditions show improvement.

General apathy featured conditions in the Kanawha district during the week ending Feb. 8, there being a smaller output in that period than during the earlier weeks of the year, production for the week ending Feb. 1 being only 81,000 tons. Definite figures are lacking as to production owing to the discontinuance of reports to some district associations and district fuel officers, but general conditions are a sufficient index. As production at times reached 220,000 tons a week during the war, it will be seen just how materially curtailed the output has been. Prices are still holding up well despite the general apathy.

Idleness among the mines also haunts the New River and Winding Gulf fields, where the general slackening of demand and lack of orders has caused many companies to cease operations for the time being, being unable to dispose of their product, with railroad embargoes in addition holding up shipments, notwithstanding the fact that some of the old market areas of both the New River and Winding Gulf districts have been restored. However, there is little need for coal there at this time, and consequently the enlarged territory is not affording much additional outlet. However, the smokeless product of the New River district will make it possible to recover from the present slump before some other districts. The advance in price after Feb. 1 would indicate that. However, labor trouble may affect the mines of the district later on.

In the Pocahontas and New River districts the total output last week was 385,277 tons, which is considered a fairly good output in view of all conditions, indicating a fairly good demand for Pocahontas coal despite the general stagnation. Production of coke declined from 52,000 tons to 44,677 tons.

In common with other districts there were heavy production losses in the Guyan or Logan mining district, the output running less than half the usual full time production. Indeed, the Logan mining district has been affected to the same extent as the Kanawha district by present market conditions, since most of the product of the mines of the district is shipped to the West. Coal will continue to be shipped through a forwarding bureau at Russell, Ky.

New York, N. Y.

The award of the contract for supplying about 300,000 tons of bituminous coal for the transport service, New York harbor delivery, is expected to be made the latter part of this week. The bids, which called for a tonnage to be called for at the rate of about 60,000 tons a month for five months beginning Feb. 1, were opened in the Army offices, 104 Broad St., on Feb. 10. Altogether twenty coal concerns submitted proposals, the prices being for net tons, f.o.b. New York harbor loading ports, and are exclusive of war freight tax except where specified. The bids follow:

	Per Ton
W. A. Marshall & Co., Pools 1, 9, 10 and 71	$4.82
Stineman Coal & Coke Co., Pools 1, 9, 10 and 71, for April, May and June.	4.87
American Fuel and Shipping Co., Pools 1, 9, 10 and 71	4.47
E. I. du Pont de Nemours & Co., Pools 1, 9, 10 and 71, for February and March	4.87
Whitney Coal Mining Co., Pools 1, 9 and 10	4.54
Rockhill Iron and Coal Co., Pool 1	5.09
Rockhill Iron and Coal Co., Pool 10	4.49
George D. Harris & Co., Pool 10	4.77
Alden Coal Mining Co., Pools 1, 9, 10 and 71 (Two delivery periods)	4.36 and 4.49
Coale & Co., Pools 9 and 71	4.62
Maryland Coal and Coke Co., Pool 9	4.88
Berwind-White Coal Mining Co., Pool 1	5.60
Emerson & Morgan, three bids, Pools 10, including war tax	4.65, 4.65 and 4.85
Pennsylvania Coal and Coke Corporation, Pools 1, 9 and 71	5.02
Pennsylvania Coal and Coke Corporation, Pool 10	4.87
Thorne, Neale & Co., Pool 10	4.92
Mountain Coal Co., Pool 1	5.42
Consolidation Coal Co., Pools 9 and 71	4.87
Campbell, Peacock & Kinzer, Pools 9, 10 and 71	5.00
N. B. Nicoll & Co., Pools 10 and 71	5.35
Knickerbocker Fuel Co., Pool 9	4.66
Knickerbocker Fuel Co., Pool 10	4.41
Davis Coal and Coke Co., Pools 9 and 71	4.80

Victoria, B. C.

The total amount of coal produced by the collieries of Vancouver Island for the month of January, 1919, was 158,327 tons. This is 18,040 tons more than was produced during December, 1918, and 55,632 tons more than the production of November, 1918. The total of 158,327 tons only lacks 2831 tons of being equal to what was produced by all the coal mines of the Province in November, 1918, and is 10,000 tons in excess of the largest production in the history of the Vancouver Island collieries.

The Canadian Collieries (D), Ltd., leads in production with a total of 80,696 tons from its different collieries, with the Canadian Western Fuel Co. second with a

production of 64,404 tons from its Nanaimo colliery.

The new No. 5 mine opened by the Canadian Collieries (D), Ltd., at South Wellington has an output of 7813 tons for January. The Granby Co.'s new mine at Cassidy, V. I., produced 2446 tons. Both of these mines should now rapidly increase their production.

The Canadian Western Fuel Co.'s new Wakesiah mine is now nearing the time when it will become an active producer, which should augment that company's tonnage in the near future. Both shafts are now down to coal and connected, and arrangements are under way laying out the shaft bottom arrangements.

These three new mines should give a good account of themselves during 1919, and considerably increase the tonnage produced from the Vancouver Island mines.

PENNSYLVANIA

Anthracite

Scranton—When the Continental colliery of the Delaware, Lackawanna and Western Railroad Co. closed recently, Thomas McGraw had been employed for fifty-one years at the colliery.

Upper Lehigh—Employees of the J. S. Wentz Co. are being sent to Raven Run, Schuylkill County, where the firm is opening a new operation. On account of the slack time at the mines the Lehigh Valley R. R. has laid off 20 firemen and trainmen on the Mahanoy division who formerly were members of coal crews.

Hanover—George Lazarus and others, lessors of coal land, have brought proceedings in equity against the Lehigh and Wilkes-Barre Coal Co. and ask pay for all coal lost by reason of excess of waste by modern methods of mining and preparation since the execution of a lease, and also pay for culm and coal taken from the land. The suit involves thousands of dollars.

Exeter—The closing down of the Stevens colliery of the Lehigh Valley Coal Co. will not materially affect the 200 or more employees as the company has arranged for their employment at the Exeter colliery. The superintendent, David W. Evans, will also go along with the men. He will have charge of the Checker and Pittston veins. The officials of the company state that the closing down of the colliery is for economy and concentration.

Summit Hill—A number of men employed in the industrial plants throughout the Panther Creek and Lehigh Valleys are being employed by the Lehigh Coal and Navigation Co. The lack of man power is no longer felt to any considerable extent. There are evidences to show that the company intends to reduce wages of its employees, but the mine workers say they will not stand for any decrease, especially at this time.

Throop—A serious squeeze has caused considerable damage to the workings of the Pancoast colliery, controlled by the firm of Dickson & Eddy, of New York. Fortunately the cave started on the evening of Feb. 8, when no men were in the mines, but the officials were able to rescue all the mules. It is said that the squeeze is affecting the main shaft, which has started to bulge, and may ruin the mine. In 1911 seventy-three men lost their lives at this plant due to a mine fire.

Hazleton—The Spring Brook and Spring Mountain collieries of the Lehigh Valley Coal Co. suspended operations indefinitely on Feb. 10. Foremen are manning the pumps. A total of 680 men are idle. Work on a proposed slope at Spring Mountain and a 500-ft. haulage tunnel planned to connect the two collieries has been stopped by the order to suspend. "Independents," with the exception of G. B. Markle Co., are working from one to three days a week. Lehigh Valley collieries are working from six to seven hours a day when ordered to operate.

Bituminous

Waynesburg—John Lantz, of Gilmore township, has sold a one-half interest in a tract of coal containing 80 acres to J. B. Fordyce.

Morgan—The White mines of the H. C. Frick Coke Co. shipped their last car of coal Feb. 7. They have been abandoned by the company and conclude this company's activity in this valley. The company recently abandoned the Valley mine.

Youngwood—The Pennsylvania R. R. has completed more plans for the improvement and extension of the Youngwood Yards. A new sectional roundhouse will be erected and a new turntable installed. During the past year many improvements have been made in the yards to care for the increased traffic in this territory.

Point Marion—The Locust Hill Coal Co. secured a temporary court injunction restraining P. J. Joyce from acting as general manager or interfering with the performance of the duties of the office, which is now held by W. J. Lester, his successor. Mr. Joyce was elected some time ago at a salary of $5000 per year.

Star Junction—Fire destroyed one of the new houses being erected here by the Washington Coal and Coke Co. Several of the houses were in process of erection at the time and it is thought to have been caused by a fire started in a small stove by the carpenters during the day time. The fire was confined to one house.

Pittsburgh—Thomas S. Lowther, of Indiana, Penn., secretary of the Bituminous Mine Inspectors' Association, has called a meeting of all the examining boards of the thirty bituminous districts for Mar. 7 at the Seventh Avenue Hotel. The purpose is to set dates for the annual mine foremen's and firebosses' examination and to discuss the form of questions to be included in the examination.

Uniontown—The river tipple and trestle of the Hecla Coal and Coke Co. located at Isabella, Fayette County, on the Monongahela River and the Pittsburgh & Lake Erie R.R., was completely destroyed by fire on Feb. 7. The fire was caused by a short circuit in the conduit wiring which was located at the river end of the tipple. The tipple was a frame structure and was built about a year and a half ago. The loss will not affect the producing and shipping facilities as the greater bulk of the coal and coke was shipped by railroad. Through the heroic efforts of the officials of the company the railroad tipple was saved. The loss is estimated at about $30,000, which includes the conveyor belt, valued at $5500. The tipple will be rebuilt. J. H. Hillman, Jr., of Pittsburgh, is president of the Hecla Coal and Coke Co., and W. L. Affelder, of Pittsburgh, is general manager.

Brownsville—The Banning-Connellsville Coke Co., on the Baltimore & Ohio R.R. between McKeesport and Connellsville on the Youghiogheny River, has indefinitely suspended operation of its plant at Banning, consisting of a large mine and 76 coke ovens, on account of slack business conditions. The company ships both coal and coke. The H. C. Frick Coke Co. has also closed its White mine near Morgan, Fayette County. It is reported that the employees of the Harah Coal and Coke Co. have accepted a wage reduction of 25 to 30 per cent. to keep running.

The Alicia mine and 400 coke ovens of W. Harry Brown, just above Brownsville on the Monongahela River, were closed down on Feb. 11 for an indefinite period, on account of lack of business. Most other operations in the Connellsville coke region are being greatly curtailed. The same is also true of the mines in the Pittsburgh district.

WEST VIRGINIA

Minden—Without orders for their product an unusually large number of mines in both the New River and Kanawha fields have suspended operations. One of the largest companies affected is the New River Consolidated Coal Co. whose mines at this place were shut down about Feb. 1 for an indefinite period, employees being told that it would be wise to look elsewhere for employment. As many as one thousand men are left without employment as a result of this shutdown. Heretofore the Minden mines have been operated regularly.

Morgantown—Damage to the extent of approximately $5000 or $6000 was done by a runaway trip of forty mine cars which demolished the tipple of the No. 5 mine of the Elkins Coal and Coke Co. on Deckers Creek, Wednesday, Feb. 5. There is a heavy grade from the mouth of the mine to the tipple below. When the string of cars got beyond control men in the tipple below, warned by the roar of the cars, fled in every direction. There was no one to manipulate the derailing switch and the cars crashed into the tipple, crumpling it up as if it had been so much paper.

OHIO

Canton—The Stark County Coal & Limestone Co., recently formed, will soon start a stripping operation about seven miles southwest of Canton. A steam shovel will be installed. It is proposed also to mine limestone, which is found in the same locality.

Corning—The Essex Coal Co., of Columbus, has opened a new mine on the Sunday Creek side of the Hocking Valley, near Corning. The mine has a shaft 130 ft. deep located in the center of the 500-acre tract, which contains a seam approximately 12 ft. thick. The capacity is 2000 tons daily. The Toledo & Ohio Central R.R. serves the property. It is operated by a subsidiary company known as the Ohio Mining Company.

INDIANA

Clinton—A gas explosion at Jackson Hill No. 5 mine recently caused the death of three men, one being Robert Laird, assistant mine boss, and the other two laborers. The explosion occurred at seven o'clock in the morning when only a few of the men were working. These men reported the accident and organized a rescue party.

Bicknell—The American mine at Bicknell has been called the "one million ton mine," because of its feat of sending to market last year more than one million tons of coal, which is one-twenty-ninth of all the coal mined by the 400 mines of Indiana last year. A second mine has been sunk by the American company at Bicknell, and a third one is to be sunk soon, each of these to be larger than the present holder of the world's record.

Belleville—Seven men were trapped in the Little Oak mine recently when a fire started in the motor barn underground. Two of the seven men made a detour of three miles to get to an oulet, where they were stopped from ascending by dense smoke. They were compelled to make another detour of two miles before they were able to make their exit through an old air hole. Twelve men were in the mine at the time the blaze started but only seven were trapped. The fire started from a torch used by men making repairs on motors. Five tanks containing 30 gal. of gasoline each were hurriedly removed to a place of safety. About 300 men will be thrown out of work until repairs are made.

ILLINOIS

Carlinville—The Chicago & Alton Railway Co. has notified Mulville Brothers to commence as soon as possible the work of putting in double track from Nilwood, Ill., to Carlinville. This new work will mean double track all the way from Chicago to Carlinville and will enable the movement of an increase tonnage to and from the mines of the Standard Oil Co. at Carlinville and Schoper.

Murphysboro—The Murphysboro Mining Co., with headquarters in St. Louis, Mo., is prospecting for coal on land along the Groves and Sand Ridge branch of the Illinois Central. Options have been secured on more than 2000 acres of land in Ora township, and testing has been finished on part of it. Drilling is under way now and has been for the past two weeks or more. Numerous mines have been opened in Ora township during recent years.

De Soto—The Benton-Big Muddy Coal Co. is sinking a mine north of De Soto. The Union Colliery Co., which is now operating the largest soft coal mine in the world north of Elkville, at Dowell, known as the Kathleen mine, is preparing to open another mine east of Elkville, probably equally as large as the Kathleen mine. Canalization of the Big Muddy River from these coal fields may take place at some future date, as it would furnish a water freight transport from the coal fields to St. Louis and Chicago, with an extension of a canal from the Big Muddy at Sand Ridge to the Mississippi River and a lock dam at Sand Ridge.

KENTUCKY

Cary—The Federal Coal Co. at this place, lost a commissary by fire on Feb. 10, loss being estimated at $25,000, with insurance of $10,000. Incendiary origin appears to be proven, as the building was found on fire at three points.

Straight Creek—The Liberty Coal and Coke Co. has secured fresh contracts, which it states will insure fair operation for some weeks to come. The mines had been operating less than half time for several weeks, but expect to go to a full-time basis.

OKLAHOMA

Muskogee—The office of United Mine Workers of District 21 at this place has been advised that the Choctaw Coal Mining Co. has closed down its mine at Coalgate, thereby throwing 260 men out of employment. It is officially announced that more than 600 men were affected by the curtailment of mining operations at Lehigh, Okla. The operators assign the mild winter and the fact that the vast majority of domestic consumers were induced to lay in their winter's supply of coal last summer, thereby decreasing the immediate demand, as the cause for the curtailment of coal-mining operations. All wholesale and retail coal dealers in Oklahoma and Texas, who normally depend on the Oklahoma fields, report large stocks of coal on hand with small demand.

Marshall—Lignite in large quantities has been found near here. A movement is on foot for the organization of a company to mine the fuel, which is said to be of exceptionally good quality.

Howe—The Texas Steel Co. of Beaumont, Texas, through its president Col. L. P. Featherstone and its secretary, W. A. Brown, has purchased 51 per cent. of the capital stock of the Howe-McCurtain Coal and Coke Co., of Howe, Okla. It is planned to operate the coal mines and 100 coke ovens of this company located at this place to full capacity and to ship the coke to the furnaces of the Texas Steel Co. at Rusk, Tex., to be used in reducing the brown iron ores of East Texas to pig iron. Later it is planned to ship the coke to Beaumont for operation of the furnaces of the Texas Steel Co. now being built there. It is declared that the iron reduction business will be revolutionized, as there is an unlimited quantity of iron ore in East Texas and the low sulphur content coke from the Howe ovens will make possible the reduction of this ore at a cost from $5 to $6 a ton less than it is possible to reduce the ores in the Pennsylvania iron belt. The Howe ovens will have a capacity of 600 tons a day, and it is planned to ship this entire output to Texas.

MONTANA

Roundup—The Republic Coal Co., with fifty less men employed and twelve less operating hours last year exceeded the highest previous twelve months' production record, made in 1916, by 45,575 tons, according to Superintendent William Redshaw. The 1916 tonnage was 615,000 tons as compared to 659,575 tons for 1918.

WASHINGTON

Cokedale—Satisfactory settlement of a strike declared by the new union of coal miners here has been announced. A new agreement between the men and the Cokedale Coal Co. has been drawn up.

Colville—The Colville Valley Coal Co. has now driven its shaft a distance of 197 ft., where it encountered a coal seam 7 ft 9 in. thick and lying between well defined walls. The shaft is being sunk on an incline of 31 degrees.

Personals

John Kaiser, of Columbus, Ohio, formerly with the General Hocking Fuel Co., has accepted a position to cover Ohio for the Elk River Coal and Lumber Co.

H. R. Blackford, recently chief engineer for the Consolidated Coke Co., Grays Landing, Penn., has been made general superintendent of all the mines of the company.

D. S. Hanley has been appointed general sales manager of the Pacific Coast Coal Company, of Seattle, Wash., with headquarters at 563 Railroad Ave., South, Seattle.

C. M. Snyder has been appointed mine inspector for the United Coal Corporation of Pittsburgh, Penn. He has been superintendent for one of the Pittsburgh Coal Co. mines.

Wilmot Jones, lately with the United States aviation service, has been discharged and has been appointed superintendent of the new Raven Run Coal Co. colliery at Raven Run, Penn.

Theodore R. Hermanson, formerly of the Harrison Works of the Worthington Machinery Corporation, has become associated with the Epping-Carpenter Pump Co., of Pittsburgh, Penn., as works manager.

Edward J. McKernan, chief clerk at the Lehigh Coal and Navigation Co.'s colliery at New Philadelphia, has been appointed sales manager for the subsidiary companies of the Lehigh Coal and Navigation Co.

Albert Dalley, Knightsville, Ind., has been appointed assistant state mine inspector by the state industrial board of Indiana. Mr. Dally succeeds William Moore, of Terre Haute, Ind., who resigned recently.

C. C. Slater, who has been manager of a mine in the Monongehela Valley, Pennsylvania, has been made manager of the Columbus Railway, Power and Light Co., of Columbus, Ohio. He has resigned his position at the mine.

George H. Ruppert who, before his entry into the chemical warfare branch of the service had charge of a sodium-ferro cyanide department of the Semet-Solvay Co., has accepted a position as advisory engineer with the Powdered Coal Engineering and Equipment Co., of Chicago, Ill.

Willis B. Clemmitt has joined the engineering staff of the Powdered Coal Engineering and Equipment Co., of Chicago, Ill., in the capacity of advisory engineer. Mr. Clemmitt was formerly assistant superintendent of the open-hearth department of the Central Iron and Steel Co. at Harrisburg, Penn.

J. H. McMillan, Provincial District Inspector of Mines for the Prince Rupert (B. C.) District, has resigned in order to take the position of general manager of the Jasper Park Collieries, Ltd., operating in the Province of Alberta. Mr. McMillan's headquarters will be at Pocahontas, where the company's largest colliery is situated.

R. B. Hullhorst, formerly Northwestern sales manager, with an office in Minneapolis, for the Old Ben Coal Corporation, has resigned from that concern and made a connection with C. M. Moderwell & Co., of Chicago. It is understood that Mr. Hullhorst is financially interested in Moderwell & Co., and will represent them in the Northwest, having his headquarters in Minneapolis.

Ainslie A. Gray, who served the United States as major during the war period, has received his honorable discharge and has opened offices at 1547 Marquette Building, Chicago, Ill., under the firm name of A. A. Gray & Co. The organization will help solve manufacturers' problems in production, advertising and selling. It will handle accounts in trade, technical and national mediums.

Brigadier General Richard Coulter, of Greensburg, Penn., president of the Keystone Coal and Coke Co., one of the large operating companies in Uniontown, Penn., was chosen at a recent meeting of the Pennsylvania Democratic State Committee as the party's candidate for Congress from the Westmoreland-Butler district, to succeed the late Congressman E. E. Robbins. The election will be held Mar. 4.

T. W. Armstrong, widely known in petroleum circles, has been appointed second vice-president of the Hulburt Oil and Grease Co., Inc., manufacturers of petroleum products at Philadelphia, Penn. Mr Armstrong will have direct charge of the Pittsburgh office and under his supervision will be the mining division of the company, specializing in the lubrication of mine equipment. Mr. Armstrong was formerly with the Keystone and Pennsylvania lubricating companies and is known throughout the state as a most efficient lubricant engineer.

Coming Meetings

New England Coal Dealers' Association will hold its annual meeting March 19 and 20 at Worcester, Mass. Secretary, C. R. Elder, Boston, Mass.

National Foreign Trade Council will hold its sixth convention at the Congress Hotel, Chicago, Ill., April 24-26. Secretary, O. K. Davis, 1 Hanover Square, New York City.

Canadian Mining Institute will hold its annual meeting March 5-7 at the Windsor Hotel, Montreal, Canada. Secretary, H. Mortimer-Lamb, Drummond Building, Montreal, Canada.

New York State Coal Merchants' Association will meet Thursday, Feb. 27, at the new Pennsylvania Hotel, New York City. Two sessions are to be held, followed by a dinner at which addresses are to be made by prominent speakers. Secretary, L. V. Shepard, Elmira, N. Y.

Industrial News

Pikeville, Ohio—The Kentenia Coal Sales Co. has filed a petition in voluntary bankruptcy in the United States Court at Cincinnati, showing liabilities of $14,733.48 more than its assets.

Wellston, Ohio—The Morrow Manufacturing Co. has established a branch-selling office at Knoxville, Tenn., and in future all business intended for the Southern territory should be addressed to the Tri-States Machinery Co., Knoxville, Tenn.

Charleston, W. Va.—The Paint Creek Coal Mining Co. has renamed some of its coal-mining towns on Paint Creek. The town of Old Detroit has been changed to Glen Buddy. Collinsdale is the new name for Hickory Camp, and Greencastle is now Ireland.

Bloomington, Ill.—The Chicago & Alton is storing 50,000 tons of coal at North Springfield and is also storing coal in Rogers ballast cars at Normal, Ill. The company is also storing 8000 tons of coal for the Chicago, Peoria & St. Louis at Ridgely, Ill.

Norfolk, Va.—The Virginian Ry. new car dumper at Sewalls Point is now in operation. U. S. Navy Collier "Orion" was loaded at the Virginian Pier at Sewalls Point on Feb. 13 in six hours and twenty minutes, taking 9622 gross tons of cargo and bunkers. This excellent dispatch is due to the efficiency of the new car dumper.

St. Louis, Mo.—The Mancha Storage Battery Locomotive Co. announces that Carson W. Smith, who formerly represented the company in Denver, Colo., has been elected secretary of the concern. This leaves the Mancha company without a Denver representative at present, but arrangements are being made and the name of the new representative will be announced shortly.

Urbana, Ill.—The Student Branch of the American Institute of Mining Engineers was reorganized by students of mining engineering of the University of Illinois under the leadership of Prof. H. H. Stoek, head of the department of mining engineering. This work was laid aside during the period of the war, but the mining engineering students state that they expect to formulate plans which will make the Urbana Student Branch of the American Institute of Mining Engineers one of the most active and profitable in the country.

San Francisco, Cal.—Coal received from all sources in San Francisco during the twelve months of 1918 amounted to 224,638 tons, according to the figures compiled by the marine department of the Chamber of Commerce. These receipts were divided as follows: From British Columbia, 82,581 tons; from Washington, 12,352 tons; from domestic rail, 129,705 tons. During the year there were no cargoes from Australia, Great Britain, the European Continent or Japan. There was brought by rail during the year 4690 tons of coke. The following are the coal receipts for the past eight years: 1917, 477,127 tons; 1916, 395,864 tons; 1915, 407,887 tons; 1914, 372,105 tons; 1913, 452,310 tons; 1912, 463,041 tons; 1911, 583,034 tons; 1910, 534,258 tons.

Seattle, Wash.—Vice President and General Manager N. D. Moore, of the Pacific Coast Coal Co., has added to the personnel of the firm by the appointment of S. H. Green as assistant to the vice president and the appointment of W. J. Santmyer as advisory engineer with full jurisdiction over its powdered coal department. Mr. Santmyer was formerly superintendent of the steam department for the Puget Sound Traction, Light and Power Co. He was electric engineer for the E. P. Allis Co., predecessor to the Allis-Chalmers Co., and was chief engineer for the Baltimore & Ohio Ry. power plant at the time of the electrification of the Baltimore belt line tunnel, the first important electrification of the kind in the country.

Charleston, W. Va.—Though unfavorably reported by the Committee on Mines and Mining of the West Virginia Legislature, the Blizzard bill requiring all companies to install scales and to pay all miners by actual weight was not rejected when reported to the House. When the question of rejection came up for consideration, Delegate Blizzard made a motion that the bill be placed on first reading instead of being rejected, so that the Legislature might consider the bill on its merits. On the other hand, Delegate J. S. Thurmond of Greenbrier, urging rejection of the measure, argued that there was no demand for such a law as was proposed from sections where there were no scales and that the proposed law would only impose unnecessary burdens on operators at a time when such operators were least able to bear them. However, the House by a vote of 58 to 16 placed the bill on the calendar instead of rejecting it.

Greensburg, Penn.—Approximately 15,000 tons of coal were mined and 1,000,000 tons of coke manufactured and shipped from Westmoreland County during 1918, according to statistics which have recently been completed. While the output of the larger concerns was slightly less than during 1917, this was due in a general way to the labor shortage. This deficit in tonnage of the larger companies was more than made up by the establishment in this county during the latter part of 1917 and early in 1918 of more than 200 small operations. Wages of coal miners during 1918 were the highest ever paid. Statistics show that miners generally averaged at least $6 per day during the year. This is an increase over the previous year of approximately $1.75 a day. The average yearly earnings of miners for 1918 were $1800, while the amount earned by many thrifty miners was more than $2500 to $3000 for the year, or $250 per month. While $150 was the average monthly wage, many miners drew as high as $400.

MARKET DEPARTMENT

Weekly Review

Lowered Output of Both Hard and Soft Coal, Due to Lack of Demand — High-Grade Soft Coal Maintaining Price Level—Anthracite Inquiry Slumps Because of Mild Weather—Increase Expected in Prices of Hard Coal

THE output of both anthracite and bituminous coal from week to week continues to reflect the stagnant condition of the coal market. Not a mine in the country is working at full-time capacity. Furthermore, hardly a day passes that does not see an addition to the already long list of operations forced to shut down because of the surprising lack of demand for coal.

The production of soft coal for the week ended Feb. 8 (the latest statistics available) amounted to only a little more than eight million net tons. This is a drop of more than two and one-half million net tons when compared to the output of the similar week of 1918, and a decrease of over six million net tons when set against the high peak reached during the week ended July 13, 1918.

Certain grades of bituminous coal are still reported as being sold at concessions from the Government maximum, though the high-grade coals are being sold at from 15c. to 45c. above the maximum prices, with perfect satisfaction to the consumer. Operators are adhering to their policy of shutting down rather than sell at a loss. Having virtually done a winter business during the summer, most operators are content to do a summer business this winter, biding their time until demand again becomes active. Little contracting is reported, most large consumers awaiting the outcome of the railroad fuel controversy.

Owing to the continuance of moderate temperatures in the anthracite-consuming sections, consumption of hard coal has failed to meet expectations. Many collieries have curtailed operation, a number of them taking advantage of the lull to make much-needed repairs and extensions to their plants.

The output of the hard coal mines during the week ended Feb. 8 is estimated at 1,144,000 net tons, which is the lowest production recorded in the past few years. It would not be much of a surprise in some quarters to see an increase in the price of certain sizes of anthracite in the future. Predictions are freely made that this increase will go into effect by Apr. 1, if not sooner.

WEEKLY COAL PRODUCTION

Bituminous—Estimates place production of bituminous coal during the week ended Feb. 8 at 8,040,000 net tons, which falls 291,000 net tons below the production of the week of Feb. 1 and 2,521,000 net tons below the corresponding week of 1918. The average production per working day during the current week is estimated at 1,340,000 net tons, as compared with 1,860,000 net tons for the coal year to date and 1,744,000 net tons for a similar period of last year. The production for the coal year to date, now estimated at 502,107,000 net tons, exceeds the production of last year for the same period by 31,129,000 net tons. A continuation of the low production recorded during the past few weeks for the balance of the coal year will cut this excess down approximately one-half, and production for the coal year ended Mar. 31, 1919, will not exceed 565,000,000 net tons.

Anthracite—A considerably greater decrease than in bituminous production occurred in the anthracite output for the week ended Feb. 8, this decrease amounting to 377,000 net tons, or approximately 20 per cent. below the output of the week of Feb. 1. The production during the week of Feb. 8 is estimated at 1,444,000 net tons, and is the lowest production, with the exception of Christmas week, 1918, recorded during the past few years. The average production per working day during the current week is estimated at 241,000 net tons, as compared with the daily average for the coal year to date of 310,000 net tons, and as against the daily average of the coal year to date of 1918, of 317,000 net tons. The total production for the coal year to date now amounts to 83,807,000 net tons, as compared with 85,528,000 net tons during a similar period of the 1917-18 coal year.

Car Loading—Carriers' reports for the week ended Feb. 8 show that car loading decreased in all districts during the week with the exception of Ohio, southwestern Virginia and the district including Illinois, Indiana and western Kentucky. In Ohio the increase in cars loaded amounted to 760, in southwestern Virginia to but 112, and in the Illinois, Indiana and western Kentucky District to 2467. The greatest decreases occurred in the central Pennsylvania and southern West Virginia fields. In the former district the decrease amounted to 4511 cars and in the latter district to 1125 cars.

New England Shipments—Shipments of bituminous coal to New England during the week ended Feb. 8 are estimated at 283,217 net tons, and are 5.3 per cent. below the shipments of the week preceding. This decrease is entirely attributed to shipments by rail, which amounted to 106,848 net tons, and fell 25.3 per cent. Tidewater shipments, amounting to 176,369 net tons, increased over the week preceding by 13 per cent., all harbors reporting improvement. Total shipments to New England for the coal year to date now amount to 22,617,592 net tons, of which total rail shipments amount to 8,595,567 net tons, and tidewater shipments to 14,022,025 net tons.

Tidewater Shipments—Tidewater shipments from the North Atlantic ports and Hampton Roads, during the week ended Feb. 8, amounted to 670,445 net tons, exceeding shipments of the week preceding by but one-half of one per cent. Shipments from Baltimore increased 8 per cent. and from Hampton Roads 8.8 per cent., while New York and Philadelphia shipments decreased 8.5 per cent. For the coal year to date shipments by tidewater now amount to 37,434,908 net tons, which total comprises shipments from New York and Philadelphia of 18,105,978 net tons, from Baltimore 3,292,220 net tons, and from Hampton Roads 16,125,710 net tons. Carloads of bituminous coal on hand at all harbors, on Saturday morning, Feb. 8, amounted to 12,765.

Beehive Coke—The production of beehive coke in the United States during the week ended Feb. 8 is estimated at 504,000 net tons, and is a decrease of 29,000 net tons, compared with the week of Feb. 1, and a decrease of 13,000 net tons, in comparison with the corresponding week of 1918. The average production per working day, during the current week, is estimated at 84,000 net tons, as against 89,000 net tons during the preceding week, and 86,000 net tons during the week of Feb. 8 of last year.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running a little less than for the same period of 1918. Road sales for at-once delivery are slightly ahead. Merchants are placing liberal orders for handkerchiefs, delivery to be made in the fall. Retail business continues excellent. Collections are continuing good.

Bradstreet's—Trade advices are a shade more cheerful, the movement of peace-time industries outside of textile lines is a trifle faster, and collections are a bit better. These statements, of course, must be taken with knowledge of the fact that buying, especially of wearing apparel at wholesale, is conservative and not equal to that of a year ago; that rain or snow the country over has checked country trade and marketing of products, especially of corn and hogs at the West; that lower cotton prices discourage southern buying and promote talk of crop area reduction; that a great many textile-mill hands are striking or otherwise idle, pending the settlement of the shorter week issue, and that the number of unemployed is larger, owing mainly to the continued releases of men from the army.

The Iron Age—Further cutting of prices is now being admitted by producers as necessary to kindle the interest of buyers. The conclusion reached is that lack of important inquiry in the past nine weeks or open market conditions is in part due to maintaining a level of prices too high to encourage barter. How to get labor to recognize its part in the adjustment is the problem. A sale of 4000 tons of pig iron is noted for export and Cleveland reports an inquiry for 5000 tons for China. On 300 tons a cut of $1.80 from $31 per ton was made by an Eastern furnace, but 3000 tons for Italy was withdrawn on the price account. The demand of the automobile trade is the outstanding feature of the domestic market. Sheet mills are running at 75 per cent. of capacity and mostly for motor cars and trucks.

Dry Goods Economist—The impression seems to be gaining ground that large quantities of cotton are being held in the South and that this cotton will soon be forced on to the market through the banks calling in their loans. Evidence that this view is well founded is presented by the continued decline in price. March options were quoted on Thursday at 22.22 cents as against a fraction below 24 cents a week ago. Mills and dealers continue to show unwillingness to buy wool at the upset prices below which the Government will not dispose of its holdings. This attitude was clearly evinced at last week's auctions in Boston, when a large proportion of the offerings had to be withdrawn. Further reductions have been made by jobbers in prices of ginghams, prints and percales. Some of the drops are as great as 40 per cent.

American Wool and Cotton Reporter—In the Boston wool market there is an undercurrent of strength and considerable anti-

mism is expressed by a number in the trade. The labor difficulties have not been universal as the woolen mills have not been affected. These mills are scattered all over the country and are better situated in this respect. The technical position of the cotton market is bullish. The South is holding strong in spite of labor conditions and the decline. Cotton owners in the South are selling their low grade cotton first, if possible, and holding the higher grades for more advanced prices. Two factors at least tend to maintain strength in the cotton market. One is that jobbers are bound to get rid of all surplus high priced goods in filling their orders and another is that as soon as the peace treaty is signed, it is expected that Europe will buy a large amount of low grade stocks.

Dun's—More than any other single factor, and with increasing force, the price question dominates the economic situation. Response has come quickly in the isolated cases where recent readjustments have largely met buyers' anticipations, but price deflation has not yet gone far enough to induce general and vigorous operations, and the hoped-for trade revival still waits. Purchasing only for immediate and well-defined necessities, continuing the rule for many weeks in most leading branches, has brought a sharp industrial reversal, and strikes have been but a contributing cause of the steadily diminishing activities and lessening employment of labor. While manufacturing is not on a uniform basis, plants in the West being relatively busier than those in the East, and some lines doing better than others, hesitation remains a conspicuous feature in all directions and not a little machinery is standing idle solely through lack of orders.

Atlantic Seaboard

BOSTON

Market shows no change. Water-borne coal practically at a standstill. Steam-users with tidewater facilities alarmed over inaction on shipping situation. Other difficulties. Railroads take only small tonnages. Large number of shippers, both rail and water, without effective orders. Dullness at Hampton Roads and New York reflected here. Slight scattering demand all-rail, but confined to small users. Several textile plants shut down because of wage differences. Georges Creek offered for smithing. Anthracite price program rumored. Will the market stand it? Inequalities as to rates of freight need correction. Dearth of inquiry except for hand-to-mouth use. Mild weather and light retail demand.

Bituminous—The extreme dullness that has settled down over the market like a wet blanket continues without any special development. Factors in the trade have about given up making any serious effort to get business for the present, so entirely discouraging is the current situation. Orders are scarce and prices on distress coal are at a low ebb. Mines, steamers and rehandling plants, in all of which New England shippers are interested, are many of them without a wheel turning. There is no reasonable hope of improvement until well into the spring, if then. There are large stocks to be worked off in every direction, and who would buy water coal today unless he were under obligation to accept deliveries on contracts made dring the stringency? There is nothing for the trade to do but mark time and wait for better things.

Not in years has there been a time when so little steam coal has moved by water. No shipper is hardy enough to venture cargoes on the market for disposition on arrival at this end, and even those who have rehandling plants are moving so little to their inland trade that there is no storage available for any greater volume of coal than is now coming forward. Some of the smaller rehandlers are even taking small supplies all-rail rather than take the chance of lower prices by water. There is no confidence in present price levels on the smokeless grades from Hampton Roads and there are still enough cargoes afloat that were shipped on old contracts to consignees now unable to take them to depress the spot market for a long time to come. There are cases where barge transportation was chartered last spring and summer in the broadcast fashion that then prevailed, but now that tows are moving regularly and loading dispatch is almost instantaneous the barges are making trips must faster than the coal can be used or stored. The result is an accumulation of barges at points like Providence with some very heavy bills for somebody to pay. As previously reported, the best obtainable price on some of this distress coal is a figure less than the f. o. b. level at Hampton Roads, wiping out the $3 or more freight which the barge owners collect. There are likely to be still heavier losses if shippers continue to load transportation that consignees are not in position to receive.

The railroads are taking only small tonnages of supply coal. Aside from a limited movement in railroad-owned barges from Port Reading, N. J., most of the railroad fuel now coming forward is shipped all-rail with almost no new purchases. Operators are doing their best to encourage buying by the railroads, some very lower prices having been rumored. It is said that $1.70 per net ton has been quoted by producers in central Pennsylvania, but no one believes any comprehensive tonnage has been placed even at that low figure.

The number of operations closing down seems to increase each week. This is true in West Virginia, in central Pennsylvania, and in the Pittsburgh districts as well. Operators represented in this market report that they have enough contract business on their books but that the consignees are still unable to accept deliveries because of large stocks and poor business. The large mills of the American Writing Paper Co., at Holyoke, Mass., are running on about a 25 per cent. basis, so little demand is there for their output. Certainly there has seldom been a season when coal conditions were so absolutely dull at Hampton Roads and at New York, where there have been practically no sales of certain grades for weeks at a time. And there is not likely to be inquiry from this territory until buyers are given some assurance that shipping and other difficulties will be straightened out.

All-rail there is a little better demand for spot coal, but it is partly induced by low prices. In any case the improvement is very slight, and is confined to scattering sales to small consumers whose storage was too small last year to load up to the extent that was true of others.

One of the results of the removal of zone restrictions is the reappearance of Georges Creek in this market. The price, $3.50 f.o.b. mines per net ton, is so high, however, that it is being bought only in car lots for forge purposes.

Anthracite—It is now intimated that the program is to make no reduction this year on domestic sizes. In other words, instead of the usual 50c. drop Apr. 1, the plan is to continue the present price basis until May 1, when the price will begin advancing 10c. per month until the maximum is reached in September. The advertisements last week throughout this part of the country were understood to be part of a campaign to prepare the public for such an advance, the farewell address of the U. S. Fuel Administrator being liberally quoted in support of the operators' views. There is a distinct feeling among the trade that prices are too high and cannot be made to prevail without widespread criticism. There is a feeling also that too much reliance has been placed in cost estimates submitted by small independent operators who in normal years have not been able to put coal on the market in competition with interests in better position to produce coal at medium cost. In other words, there has seemed to be a disposition to lift the price so that any operator could mine coal at a profit whether his particular output was necessary to the market or not.

Inquiry for anthracite is very light. The mild weather has affected retail demand, and householders will buy only from hand-to-mouth, there is much faith that prices are bound to be lower. Straight cargoes of stove or chestnut are now easily to be had and practically every shipper is hard at work soliciting orders, although with very little success.

NEW YORK

Local situation dull and buying is restricted to actual needs. Conditions are unequaled. Coal in oversupply at time of heaviest consumption. Trade looks for change in prices either up or down. Anthracite may be pooled. Bituminous situation quiet. Plenty of coal and many loaded boats in the harbor. Concessions heard of. Operators urge shippers to sell stocks.

Anthracite—The situation here is without an outstanding feature. Buying is restricted to actual needs and as a result there is an over-abundance of coal of all sizes to be had. Conditions have never been equaled. During what is generally the best month of coal consumption there is an oversupply, very little movement and many mines either closed down or their operations curtailed. The suspension of operations is not confined entirely to the Independents, but many of the collieries of the larger operators are also affected.

Reports from the coal regions indicate an increasing amount of dissatisfaction due to the lack of work, many workers grumbling because of the reduced earnings and the H. C. of L. Replying to this complaint the operators only have to point to the lack of demand and the present supply of coal.

There is no such thing as the 75c. differential between Company and Individual coals. Shippers of the latter product are willing to dispose of their holdings at the Company schedule, but even at that they find their work cut out for them. It was reported that sales of domestic sizes have been made at 20c. per ton below the Company schedule.

The trade was interested in the publication, as an advertisement in the daily newspapers last week, of Dr. Garfield's statement made at the time he issued his order removing the restrictions over the coal industry. It felt that it meant an increase in prices, and while no announcement has come from the operators, it is the belief among the trade that the present schedule will remain in effect until Apr. 1, and that the usual monthly increase of 10c. per ton per month for five months will follow.

There are some coalmen, however, who frown upon any intimation of an advance, claiming that the present is no opportune time to increase the price of coal to the public. They say that many things can happen between now and Apr. 1 and that the situation will be governed entirely by the law of supply and demand.

The sentiment for the formation of a pooling arrangement for anthracite similar to that for the pooling of bituminous is said to be growing. Many wholesalers believe that some such arrangement must be made to avoid the heavy demurrage charges which have and will continue to accrue.

Consumers are not expected to buy heavily under present conditions. Most all have enough coal to last them from six to eight weeks, and as they expect the usual spring discount are not placing any new orders. Local dealers have more coal in their yards than at any other period during the past year, and instead of accepting deliveries are cancelling orders.

There is no improvement in the steam-coal sitaution. The cut in production has naturally reduced the output and the docks are not as well stocked as they were a couple of weeks back. Considerable variation of quotations for the three sizes has been heard, much depending upon the quality of the coal. The better grades of buckwheat have been held at from $2.50 to $2.70 at the mine, and the cheaper coals from 20c. to 30c. less. Quotations on rice coal are generally about 50c. lower than those on buckwheat.

The dullness of the market is reflected in the dumpings of anthracite reported for the week ended Feb. 14, when 3429 cars were dumped as against 5014 cars the week previous, a decrease of 1785 cars.

The retail situation is quiet. Many dealers having a family trade almost exclusively have hardly anything to do and their drivers are consequently idle. Many of the dealers in Brooklyn are circularizing their customers, offering to deliver to them the balance of their undelivered order placed with the Fuel Administration last spring.

Bituminous—The situation is quiet. Inquiries have fallen off and shippers with coal coming forward are wondering what is to become of it. There is practically no demand and buyers are generally able to receive quotations considerably below what they paid for coal a couple of months back.

Conditions are such that local concerns are being urged by operators to dispose of coal either here or on its way. Market conditions have not been satisfactory for some weeks, and it is as difficult now to dispose of coal as at any previous time. Buying stopped suddenly and the market was caught unprepared. There was more than enough coal here to take care of current needs, to say nothing of the quantity on its way from the mines. Wholesalers found themselves overburdened with supplies and no place to put the coal.

In addition economic conditions had intervened and factories using thousands of tons began to reduce their working hours, consequently deliveries were reduced with the result that where these factories a couple of months ago had from two to three months' coal supply on hand they now have from four to five months.

There is no market, and with the coal piling up at the piers dealers have had to force the coal on the market at reduced prices in order to save demurrage charges. The harbor is filled with loaded boats, and these cargoes have been let go at heavy concessions, according to report.

Wholesale dealers do not look for a brisk water trade for the next couple of months, or at least until there is a settlement of the labor troubles between the boat-owners and their employees. Should the latter secure a wage increase and a reduction of working hours it will naturally result in

an advance in boat rates, which will cause many dealers who can do so to order their coal sent by rail.

The local ports have been under embargo at one time or another, for the past month. Dumpings for the week ended Feb. 14 show that 5624 cars of bituminous coal were dumped as compared with 6779 cars the previous week, a decrease of 1155 cars.

There are many inquiries regarding contracts, but so far nothing definite has been done regarding price although it is said some quotations indicate prices around $3.50 for the high grade coals.

A continued curtailing of production for the next several weeks is expected to rid the market of much of the surplus coal now on hand, and it is hoped the situation will be healthy with better prices.

Quotations on high-grade coals ranged during the week from $2.50 to $2.75 at the mines, with the cheaper grades from 50c. to 75c. lower.

PHILADELPHIA

Anthracite market dull and unsatisfactory. Production is curtailed and efforts being made to prevent market from becoming overstocked. Mine workers want more work, but realize there is no demand. No immediate change expected in prices. Bituminous situation quiet. Operators curtail production and prevent heavy cuts in prices. Contract making being considered.

Anthracite—Conditions here are serious. Demand has tumbled, and there is more than enough coal on hand to meet all requirements for several weeks to come. To meet this depression the operators have placed most of the mines on a three-day-a-week basis, and it is said many of the smaller operations are not doing as well as that.

Reports from the coal regions are disquieting. Many of the workers believe there is no necessity for the present suspension of operations, and with their present earnings they find it difficult to maintain their families. However, everyone knows that the market is overstocked and that the only solution of the difficulty is a cut in mining.

Wholesale dealers have received many cancellations of orders as a result of present conditions. There has been a disappearance of the 75c. differential between Company and so-called Independent coals, but even this does not help to reduce the stocks. Retail dealers report a heavy depression with no prospects of better business ahead for several weeks to come.

Opinion regarding future prices is divided. There are many who look for no change until May 1, when they believe there will be an advance of 10c. per ton per month for five months, while there are others who expect the usual spring discount of 50c. per ton on Apr. 1. This latter report is also current in the mining fields.

The supply of steam sizes does not increase owing to the cut in production, but there is an abundant supply and quotations are easy.

Bituminous—The local situation is far from satisfactory. The market is not overstocked as is the case in other localities, but there is more than sufficient coal to meet all current requirements. While there are many reports of coal being sold at prices that will not pay the cost of production, they have not been verified and, if true, are few and far between. Operators realize that to do so would be a losing venture and one that would not pay.

There has not been a heavy cut in prices here, the trade preferring to keep the coal at the mines rather than have it sent to this market to await buyers. This procedure is likely to be followed until the market strengthens and there is a better demand. This is not expected to happen, however, for a couple of months, as most of the factories dependent upon this market have filled bins, large heaps of coal in their yards.

The matter of contract making for the next coal year is being given some attention. There have been many inquiries but little if any signing up to this time. Operators are not inclined to be hasty in closing deals for their output with the market in its present unsteady condition, while consumers believe they will be able to do better by waiting than to close up at the suggested prices. While no definite announcement has been made it is understood that the prevailing quotation on contracts is around $3.50 for the high-grade coals.

Reports from inland are to the effect that there is an abundance of coals in the various factory yards, most of it having been bought at the full Government price. As in other sections, some of this coal is being transferred to factories not so well supplied but which are under the same ownership. Until this high-priced coal is consumed salesmen fail to see much opportunity for further business.

C. H. Markham, Regional Director for the Allegheny Region, in his report for 1918 to W. G. McAdoo, Director General of Railroads, states that during December of last year anthracite coal loading increased 1456 cars, or 2.9 per cent.; bituminous loading increased 35,944 cars, or 17.7 per cent.; and all coal loading increased 37,400 cars, or 14.8 per cent., as compared with December of 1917.

Mr. Markham's jurisdiction includes the terminals on the New Jersey side of the North River, as well as the lower ports supplying the New York market. His headquarters is in Philadelphia.

Continuing his report Mr. Markham says that during December of last year tidewater coal dumped was 2,158,490 tons, an increase of 471,117 tons, or 21.8 per cent., as compared with the previous December.

BALTIMORE

Soft coal market still overstocked. Government control still remains, and brings Tidewater Exchange problems. Hard coal offered by mines on company mine-price basis.

Bituminous—Every pier approach, every line siding and all approaches generally by rail to the city show a big run of soft coal for this section. That the market is overstocked is undoubted. Prices in many cases have been still further cut. Some handlers say that they are getting some business but could handle much more; others say frankly that things are bad and that it is not now so much a question of price as it is to get someone to absorb the fuel that is here or urgently offering from producing points where the upkeep of organization at mines is essential.

The Shipping Board has recently found itself hampered by a great amount of coal that it could not handily absorb, and the ordinary shippers' business at the piers was further blocked by this Government department insisting that some incoming ships which might have taken outside fuel receive only the Government owned coals aboard.

The trade just now is discussing rather warmly the question of the Government dropping the last vestiges of control over the fuel industry. In this connection interest will be centered for a time in any possible action to follow the meeting in Washington recently of the Government Tidewater Exchange officials and prominent shippers of coal. Some warm opinions are understood to have been expressed in Washington during the meeting. The Lakes are said to be especially hot over some alleged inequalities, and at this point, while some shippers express satisfaction with demurrage apportionment, there are handlers of coal who have some kicks to register. It may be stated that with the recent congestion here a number of shippers are uneasy over the prospective size of demurrage bills with the coming month.

Anthracite—The hard coal trade here is still purchasing cautiously. Prices have not been cut here as in Philadelphia and Boston. Dealers here have always claimed that the margin of profit was too small under Government dictation. Meanwhile mines, irrespective of whether they are company owned or independent, are offering coal at the company schedule. There is more than enough coal running already than is called for by consumers. Only by forcing deliveries to the utmost through telephone call urgings, etc., is the trade prevented from accumulating a dangerous surplus in these times of high-priced coal.

Lake Markets

PITTSBURGH

Production below 30 per cent. capacity. Fairly steady market on regular lots, with demurrage coal at great sacrifices.

The Pittsburgh district coal market is almost absolutely dead. Demand is of almost negligible proportions, as to new buying, while nearly all contract shipments are greatly reduced, partly because consumers require less coal than formerly and partly because they are using up stocks. Production in the Pittsburgh district, which dropped to about 30 per cent. of capacity two or three weeks ago, is now at a somewhat lower rate still. Many mines are closed entirely while practically none are operating at capacity.

Leading operators are making a strong effort to maintain prices, but there are many producers who would cut prices if it were possible thereby to obtain an efficient operation; so little tonnage is to be sold by cutting prices, however, that there is no general disposition to do so. The really low prices that are made in the market are on coal that by one mischance or another is loaded and must be moved to avoid demurrage. Such coal has been dumped on the market at $1.50 or possibly less. Apart from such coal the market is fairly well maintained. On high grade gas and by-product coal prices are relatively stiff at about the old Government level of $2.35 for mine-run. An effort is made to maintain circular prices on contracts, circular prices being based on $2.50 for mine-run, but hardly any business has been done on this basis. A few contracts have been put through for high grade ¾-in. gas coal for the twelvemonth beginning Apr. 1 at $2.60. Apart from low prices done on emergency sales of coal loaded on track the market is quotable at $2.20@2.35 for mine-run and $2.35@2.60 for ¾-in. gas, per net ton at mine, Pittsburgh district.

There is much unrest among miners, and it is recognized that any effort to reduce wages would probably precipitate a great deal of trouble. At the moment miners are relatively contented to be idle, but their funds are not large and there may be discontent on the score of idleness. The union is rich, but it is very doubtful whether any funds would be used to support miners in idleness, unless resulting from a regular strike.

BUFFALO

Still a coal surplus. Anthracite about as much in excess as bituminous. No spring contracts in sight.

Bituminous—The coal situation does not change materially. Shippers say that the surplus is as evident a ever, and they see no return yet of the looked-for increase in consumption that is to reduce the supply and bring about an active market. Till that takes place there is not much use of looking for relief. All that can be done is to sell as much coal as possible, and when the consumer will buy no more the mines must close.

It is coming pretty close to spring, but there is little said of the usual contract period. Nobody knows what to do about it. When there was talk of advertising for waterworks coal, the largest city contract, it was said that shippers would not dare to make figures lower than the going price. Maybe that is why no bids have been asked for.

Anthracite—The trade is not going to pick up till the weather is colder, for the season is so far advanced that it is a strictly weather market from now on. From all sides come reports of more coal than is needed. Anthracite is on demurrage in Montreal, and the upper lakes are expected to be obliged to carry over a large amount of last summer's lake shipments.

Buffalo is said not to have much of a supply on hand, but that is only because nobody feels uneasy over the situation. All that the consumer is anxious about now is whether the operators are going to be allowed to advance the price. Anthracite at $10 a ton and bituminous about half that price seems out of proportion, the consumers think.

CLEVELAND

Bituminous is moving into this district at about 30 per cent. of normal. This is by design and represents the efforts of operators to keep production apace with demand. The last Government maximum prices continue to rule on all standard grades. Anthracite supplies now are in excess of the demand. Some Pocahontas is beginning to come in.

Bituminous—Southern and eastern Ohio mines are now being operated on approximately a 40 per cent. schedule, while receipts in Cleveland and the northern Ohio industrial district are about 30 per cent. of normal. This briefly tells the story of bituminous here, and gives evidence of what success operators have had in restraining efforts to force a situation that apparently cannot be forced. Operators are adhering to their platform that they will close rather than operate a a loss. While coal to the west has been advanced, $2.35 continues the mine-run quotation here. As operations at the mines grow smaller, car-service coal becomes scarcer, and concessions from the $2.35 price fewer.

The situation at Ohio mines is reported fast approaching a serious state. John Moore, president of the Ohio Mine Workers is authority for the statement that 15,000 coal miners in Ohio have not worked one day since New Year, while 30,000 have worked less than half of the time.

The retail market, like the steam-coal one, seems past all human help. One cold day is succeeded by three warm ones. Pocahontas is beginning to dribble in, but no insistent demand for it has come to the surface. Retail dealers are resigned to a summer business the remainder of this winter and all of next summer.

Anthracite—The present supply is more than ample to meet all needs, and competition for business is sharp. Stove and furnace grades are now equally plentiful.

Lake Trade—Lake coal shippers and the upper lake dock interests must make a strenuous fight to convince the Railroad Administration of the necessity of relaxing upon demurrage regulations in order to make possible abandonment of the Great Lakes coal pool, it now becomes apparent. A conference with the railroad officials at New York proved unsatisfactory, and a further meeting is to be held soon at Washington. The pool is much to the liking of the railroads, from an operating standpoint, and all of the decisions of the coal interests to resume individual shipping will be of no avail unless the administration eases up on its demurrage rules.

Early cargoes will not be in demand in the spring, as the docks at the head of the lakes still carry unusually large piles. In January only 20,430 carloads were moved off the Duluth-Superior docks, as against 30,123 in January, 1918, and 30,707 in January, 1917. Some shippers are figuring on early cargoes, though price will not be generally talked until after Apr. 1. One of the loading machines at Ashtabula, Ohio, is being put in shape and will be ready next week.

DETROIT

Little stimulus appears to have been imparted to the Detroit market for bituminous by removal of the Federal zone and price restrictions.

Bituminous—No marked improvement in the market for bituminous coal in Detroit is reported to have followed the termination of Fuel Administration zone regulations and price control. The reason, according to jobbers, is that the local situation is abnormal, due to the magnitude of stocks of coal in yards of retail dealers and in storage piles of the steam plants. Reduction of these excessive stocks proceeds slowly in the case of both classes of buyers.

Besides having their yards crowded with bituminous coal, a great deal of which is of low quality and in a form their customers don't want, the retailers are finding their business is curtailed by the competition of a better grade of stock now reaching the market, and the attempt of household consumers to end the use of bituminous as speedily as possible, since Government regulations no longer compel their acceptance of a fuel that they find undesirable in heating plants designed for use of anthracite.

Anthracite—Slight improvement in supply of anthracite is reported by some of the dealers. Because of the continuance of moderate temperatures consumption has fallen short of expectations and quite a large proportion of the retailers appear to have stocks of anthracite. Several are advertising ability to supply all domestic requirements in any size of anthracite. The plentiful coke supply also is a factor in easing strain on anthracite. There are indications of higher prices on some sizes.

COLUMBUS

The coal trade in Ohio continues quiet in every respect. Warm weather has curtailed domestic demand. Steam trade is small, as surplus stocks are still heavy. Prices are fairly well maintained.

Quietude characterizes the coal trade in Ohio territory. Owing to the continued warm weather there is little demand for domestic grades. Retail stocks are sufficient to take care of current needs, and dealers have not been forced to replenish their stocks to any extent. There is still a limited demand for Pocahontas and other fancy grades, but since the raising of the zone regulations those grades are moving without hindrance. The tone of the market is not good and there is no immediate prospect for betterment according to producers and shippers.

In the steam trade more inquiries have been received, indicating a more optimistic feeling generally. Some of these inquiries have developed into orders, but the movement is rather restricted. A canvass of the situation shows that large consumers still have heavy surplus stocks and it is their policy to consume the greater part of these surpluses before ordering more. Manufacturers are slow in getting on a peace basis and thus their fuel requirements are not large. Railroads are not buying to any extent although their orders are larger than was the case several weeks ago. Railroads are still trying to buy below the Government levels and some tonnage is moving at reduced prices. But generally speaking the larger operators are holding up on price and the market is not demoralized.

Domestic stocks are large. Householders who put in their fuel stocks last summer and fall will in many instances carry over some into next winter. This is one of the bad features as it indicates a rather slow domestic demand during the summer months. Retail prices are fairly well maintained as the larger producers and distributors are not cutting. It is realized that lower prices would not stimulate trade and there is not much desire to do business at a loss.

CINCINNATI

Colder weather is drawing upon retailers' and consumers' stocks and making room for further deliveries. Prospects for Western business improving in consequence.

The heaviest snowfall of the winter in this section occurred last week, accompanied by colder weather than has prevailed for some time. This combination has materially stimulated consumption. Retailers report a better demand for coal, especially in one- and two-ton lots, and it is believed that a continuance of cold weather will go far toward reducing the accumulated stocks in the hands of dealers and consumers.

Aside from the local situation the interest of the trade is turned toward the West, where efforts are to be renewed for the sale of coal for the coming season. An unusual indication of the extent to which the general distribution of coal along highly competitive lines is to be the rule was a large advertisement appearing in local papers last week on behalf of anthracite coal. The advertisement recounted briefly the effect of Fuel Administration action upon the distribution of anthracite, and stated that hard coal is now available for general distribution everywhere, at reasonable prices. As this fuel has never had more than an insignificant sale in Cincinnati, not to mention the rest of the Middle West, aggressive sales efforts on its behalf may afford some evidence of the way operators are going after business, especially where they are accustomed to handling it.

LOUISVILLE

Colder weather and snow improve feeling somewhat. Fair demand for domestic continues at high levels. Steam coals draggy and hard to dispose of.

More nearly winter weather during the past few days has encouraged the trade somewhat, but retail movement continues dull, with the trade buying from hand to mouth and carrying little domestic stock on hand as deliveries can be secured quickly and the average retailer is playing safe on the market.

A few retailers have been running a little low and have been rushing in orders for a few cars here and there, but the demand is not heavy. Domestic is generally keeping the operators busy on a two- to three-day running basis, but even on this small time they are having trouble in disposing of resulting fine screenings, nut and slack, etc. Prices for domestic are running 15c. to 40c. a ton higher than when regulations were lifted, while nut and slack are off 15c. to 20c. a ton average, and much more in some instances. Egg and 4-in. mine-run are in fair demand.

Many operators believe that there will be a good demand for steam within a short time as some of the overstocked industries will shortly begin running low, and rail buying should start again, while the export situation looks better. However, with an increased demand for all grades of steam, operators in many instances are figuring on a hard time in disposing of domestic coal, as not much early stocking is expected.

Retailers are generally well fixed financially this year, due to short-time credits and a preponderance of cash business. Some retailers have little money out on 1918 coal deliveries, and are in position to take discounts. However, collections are nothing like as good as they were, due to a general fight for business, resulting in bars being lifted. The operators are no longer shipping any volume of coal on a sight draft basis, as there are too many who are willing to ship on almost any kind of basis, with the result that collections have dropped off materially.

BIRMINGHAM

Steam market sluggish, with little spot business offered. Some accumulation of low and unprepared grades. Domestic demand good, there being a shortage in supply. Larger mines operating full time, while operations at the smaller ones is rather unsteady.

There is a decided weakness in the local steam coal market and the volume of spot trade is small, buying being confined to the better grades of fuel and to current requirements of consumers. There is some accumulation of Big Seam and similar grades, though not sufficient tonnage to have any weight on market conditions, as operators as a whole are holding their output to the approximate requirements of the trade. Contract users are in most cases taking the minimum tonnage stipulated in their agreements with the mines, while there are some cancellations and hold-ups on open business. However, there is no voicing of pessimism in coal circles and the future of the trade is viewed with calmness and confidence. Price schedules closely approximate the Government figures as of Jan. 31 and are firm, quotations being as follows f.o.b. mines:

	Mine-Run	Prepared Sizes	Slack and Screenings
Big Seam	$2.45	$2.75	$2.40
Black Creek and Cahaba	3.45	3.75	3.05
Pratt, Corona, Jagger	2.85	3.05	2.45

The domestic trade is strong and receipts considerably below requirements, all the better grades showing an advance since Feb. 1. Quotations are as follows:

	Lump and Nut
Black Creek	$4.50
Corona	3.65@3.75
Jagger	3.50
Montevallo	5.00
Cahaba	4.50

The mines of furnace producing companies are operating steadily, as are also most of the commercial mines, there being some loss of time at small operations depending almost entirely on the demands of the spot trade.

Coke

CONNELLSVILLE

Market soft. Further contract readjustment. Continually decreasing production.

The coke market is very soft. Operators have been making an effort in the past few weeks to curtail production in keeping with decreasing requirements of blast furnaces, but have been uniformly a lap or two behind, so that limited tonnages of coke have had to be dumped on the market, having been loaded without a destination. Such coke has been available down to $4.50 and $4.25, and some of the $4.50 coke is probably of altogether standard quality. On the other hand operators would hardly sell coke still to be made at less than $5 for furnace grade. Standard brands of foundry coke are held at $6 and some sales are being made at this figure. Generally speaking the spot and prompt market may be quoted at $4.50@5 for furnace and $6 for foundry, per net ton at ovens.

As already reported, the majority of contracts that called for negotiation as to price in the event of Government control coming off have been adjusted so that February shipments are billed at $5.50. Some adjustments, it appears, were made at close to $5. As to contracts that called for "last Government price," the pressure of furnacemen has been such that the operators quite generally have revised such contracts, to a level of about $5, this adjustment to be not specifically for the month of February but rather to stand until conditions change further. From the present outlook it is quite possible that further downward readjustments may eventually be made.

The outlook for Connellsville coke is that it will sell at no more than the cost of coking, after the coal has been priced at the market value, profit to operators being entirely on the coal. Byproduct ovens will naturally run full as they can convert the coal at less cost than the beehive ovens. Standard grades of byproduct coal are worth about $2.35 at present, which on a two-thirds yield makes about $3.50 for the value of coal used in making a ton of Connellsville coke. The coking operation, without overhead, will run considerably under $1, so that eventually the coke market is likely to be $4.50 or less, and considerably less in case the value of coal declines.

Buffalo—The trade sympathizes with coal, though the prices of the higher grades have not suffered much. The chief difficulty is that the furnaces are not buying at all liberally, as they have a big supply ahead of them. The byproduct ovens here are pretty busy, though they are not able to dispose of all their off grades and breeze, and are obliged to stock some of it. The furnaces insist on what was Government price for what they sell, which is $9.60 for 72-hour foundry, f.o.b here.

Middle Western

GENERAL REVIEW

Market conditions still inactive. High grade coals maintain price. Railroad fuel question still unsettled. No improvement in market expected until peace is signed and industry resumes full operation.

The coal markets of the Middle West continue inactive, with little coal produced and less sold. The market has had an opportunity to adjust itself to conditions brought about by the abolishing of the zones, and it is surprising to note how well prices are being maintained. All of the high-class coals from Illinois and Indiana are selling at the previous Government prices or higher. The poorer grade coals continue to be sold at a discount, which is no more than just.

The question of railroad fuel continues to drag, greatly to the dissatisfaction of the operators. It is the general opinion in coal-mining circles that the railroads and the politicians are getting together to beat down the price of coal. In view of the fact that the coal industry made an enviable record during the war, and by considerable sacrifice contributed in no small way to the successful culmination of the war, the operators almost as a unit feel that they are being ill used. They have no desire to become the pawns in a political game of chess, in spite of the best efforts of certain altruistic gentlemen in Washington.

All demand for steam coal is at a full stop, not so much because storage piles are being used, but because manufacturing of all kinds is practically at a standstill in the Middle West. Factories are closing down daily, with prospects of more inactivity in the near future. Coal men are looking for no radical change in this general condition until peace is signed and the authorities at Washington indicate to the nation what to expect.

Two large steam-coal contracts have been awarded in this territory in the last week. Both contracts were for military camps, and the combined tonnage was possibly 75,000 to 100,000 tons. It is said that some of the bids were below the last Government figures, and that the parties awarded the business cut the price. This, perhaps, is another indication that the Government is interested in price rather than quality.

The domestic situation is a little better than heretofore, except in Chicago. Throughout Illinois, Indiana, Wisconsin, Iowa and Michigan reports have come in that the retailers are once more buying. They are very careful, however, to purchase only the best to be had. The increase in price, affecting all high-grade coal from West Virginia, Indiana and Illinois, is making little difference to the trade. The dealers who are accustomed to furnishing their trade with the best are paying the price, while the others are continuing to purchase any off-grade bargain that is offered at a cut price. It is a gratifying fact, however, that the demand for good coals at a fair price, is far in excess of the demand for poor coal at a cut price.

CHICAGO

Little domestic demand owing to mild weather. Owners of storage piles anxious to get rid of them. Steam-coal demand inactive.

Chicago has been enjoying its usual bracing spring weather. One domestic dealer on the North Side reports an adventurous dandelion growing in his coal yard. This will serve to convey to the reader that there is little domestic coal moving in Chicago.

An unfortunate situation has arisen as an aftermath to the Fuel Administration's reign. There are many yards in the city that have on hand huge piles of Illinois and Indiana lump and mine-run. This coal has been in storage since last spring, or since last summer, and as a consequence is deteriorating very rapidly. As a result, the owners of this coal have been doing everything possible toward moving this storage; in fact, it was reported that some quotations on storage coal were made on a basis of $2.50 on mine-run delivered. This represents a loss of at least $3 per ton to the dealer, and it shows how anxious those who have stock piles are to get rid of them.

The steam-coal market continues inactive in the extreme, as the general lax manufacturing situation is as true of Chicago as of the surrounding territory.

MILWAUKEE

Coal trade continues lifeless. Little demand from city or country. Prices are maintained. Pocahontas mine-run reappears.

The coal trade at Milwaukee continues lifeless and discouraging to those having large stocks on hand. The month of February is usually a fuel-eater, but it is half gone and the cold wave flag has not been displayed as yet. The demand from local consumers is very light, and there are practically no calls from the country. More Illinois coal than usual was sent to the interior of Wisconsin during the past summer, and much of these stocks still remain. This lets lake dock men out of the game at present. The same conditions exist at Manitowoc and Sheboygan. Prices are maintained, however. One yard is advertising anthracite received by rail at the same price as lake coal. Bituminous egg and nut is held by the same yard at $7, with a charge of 50c. per ton for carrying in. This is a little under what other yards are charging for Eastern soft coal. Pocahontas mine-run has appeared in the market. It is held at $8.15. No other grades of the coal are offered, however. Leading dealers hold that there will be no cut in prices because of the present situation, and even intimate that an advance in anthracite might yet be necessary. Everything is being done to stiffen the morale of the trade, upon which the future of the remainder of the season's stock piles seemingly rests.

ST. LOUIS

Market continues quiet and sluggish. Coal selling below cost under forced conditions. Cars plentiful, movement good and much dissatisfaction at the mines on account of no work.

In the Standard field some mines have had screenings on hand for over a month, and several mines have not worked for over two weeks on account of the surplus of steam sizes. This condition is almost general throughout the Standard district and to some extent is also affecting the Mt. Olive district. Lump is moving fairly well because the tonnage of coal produced decreases gradually, but even at that there is no ready market for all the lump coal that is mined daily.

There is much dissatisfaction in the Standard field among the miners, who contend that they cannot exist under the present conditions. They do not understand why the operator should cut his price to the public when the cutting of the price does not sell any more coal; and if anything is to be given away, they figure that the miners should get more for the coal on account of their shorter working time and that coal should sell on the market for the Government maximum.

In the Mt. Olive field conditions are somewhat better, but also very unsatisfactory. The prices are holding up pretty well, but the coal is not moving and there is no market for it.

The tonnage in the St. Louis market is small. A fairly good tonnage continues to move north and the railroads are still taking some coal from this field.

In the Williamson and Franklin County district the mines are idle, as usual, on account of steam sizes; and some of them have not enough orders to keep them going on domestic sizes. The Franklin County field is solidly tied up on the $2.75 price for domestic sizes and operators feel that if they cannot get that they are going to stay idle.

In the Williamson County field just a few operators are asking the $2.75 price. The result is that the Franklin County operators are not working as steadily as the Williamson County independent operators, who are quoting from $2.35 to $2.55 for lump, egg and nut, with screenings as low as $1.70 to $1.80 and mine-run at $2. The independents seem to get pretty nearly full working time, but even at that every night shows their tracks occupied with cars of unbilled coal of all sizes.

The Du Quoin field is somewhat similar to the Williamson County field. Some of the operators are asking the $2.75 price, and others $2.55 and less, with no demand for the product.

The general condition throughout the St. Louis territory is not satisfactory on account of the Standard condition. If the Standard market was in better shape it would have a more wholesome effect on the whole situation.

Throughout the West it is expected that the tonnage of egg and grate will perhaps be decreased by one-half of what it formerly was the coming season, while the demand for stove and chestnut will pretty nearly measure up to past requirements.

There is everything to indicate that the price on coal in the West will have to be increased. One coal-carrying road spends $1.02 for every dollar that it takes in. There must be an increase in rates and coal will come first.

The anthracite operators have been advertising their predicament in the Western daily papers in such a way as to indicate that they must get more money on and after Apr. 1.

The present prevailing prices on retail coal in St. Louis are: Anthracite—grate and egg, $12.34; stove and chestnut, $12.60. Coke—Gashouse, $11.25; byproduct, $12.35. Bituminous—Carterville lump, egg and nut, $6; Mt. Olive lump, $5.25; Standard lump, $5.

The market here, with the exceptions as noted above, is as follows:

		Mt. Olive and Staunton	Standard
Franklin County:			
Prepared sizes (lump, egg, Nos. 1 and 2 nut)	$2.75	....	.....
Williamson County:			
Prepared sizes (lump, egg, nut)	$2.55	$2.55	(As noted
Mine-run	2.20	2.20	above)
Screenings	2.05	2.05	.....

Williamson-Franklin rate to St. Louis is $1.10; other rates, 95c.

COAL AGE

Volume 15 New York, February 27, 1919 Number 9

The Future of Coal Prices

By Floyd W. Parsons

IT IS foolish to anticipate that there will be any real lack of coal in the United States during the lives of people living today. But there is another side of the question that yearly becomes more important, and that is the growing scarcity of certain grades of coal that have been most in demand. It is a fact that in all lines of production initial output is obtained from the highest grade and most easily accessible sources of supply. So it is in coal mining. The best coals are fast disappearing, and lower grade fuels with higher mining costs are now being attacked.

Anthracite coal, which especially interests domestic consumers in the eastern part of the country, comprises only one-fifteenth of our total coal resources. It is hopeless to expect that any new deposits of anthracite will be found. Since 1807, when the Pennsylvania anthracite was first discovered, the producers of this kind of coal have mined approximately 3,000,000,000 tons. Although this large output of hard coal amounts to only one-sixth of the total deposits, the fact remains that the best seams of anthracite have been largely depleted, and operations are now in beds that are thinner and deeper.

Whereas it required 112 years to produce 3,000,000,000 tons of anthracite, we may figure that at the present rate of growth that same tonnage will be mined in less than 20 years. Furthermore, in getting 3,000,000,000 tons of coal out of the mine and into the hands of the consumer it is likely we destroy a couple of billion tons in the ground and elsewhere—a loss that is unavoidable. All this leads to a single conclusion — anthracite will never be cheaper and must of necessity be more expensive as time passes. There will be advances in the art of mining, and these improvements in methods and machinery will undoubtedly reduce costs; but all such savings will be more than counterbalanced by increases in wages, higher prices for supplies and greater mining charges due to working less favorable seams.

Let us therefore, dismiss anthracite from our calculations and devote attention to bituminous coal.

Geologists tell us that in the United States we have about thirteen hundred and fifty billion tons of bituminous and semi-bituminous coal; of these huge reserves we have mined about thirteen billion tons and wasted at last 50 per cent. as much. In the face of such large resources this total exhaustion of less than twenty billion tons seems hardly worth noticing, but here is the trouble: Of our total bituminous deposits less than 5 per cent. contain coals that are today regarded as high-class fuel, and it is this better grade coal we have been mining.

Already in many parts of the United States there is an apparent scarcity of high-grade fuel. As time passes this shortage in special coals will become more acute, and will be felt in fullest force in the middle and northern Atlantic States. A great many people overlook the fact that 45 per cent. of our population inhabits 11 per cent. of our area. In New England, New York, New Jersey and Pennsylvania there are eleven times as many people on each square mile as there are in the West. In this congested eastern region, there are 700 people for every mile of railroad, while in the West there are only 252. Of all the manufactured goods produced in the United States nearly 70 per cent. originates in this small eastern area.

The industrial development of America is far from being uniform. The result is that we have a small eastern territory buzzing with business activity and entirely lacking in any native supply of coal. Furthermore, this congested region has no oil or natural gas and possesses only limited water-power.

The great cry on the part of coal consumers is for the best obtainable fuel, since it is well known that high-grade coals purchased at a reasonable price are most economical. Furthermore, various plants such as those serving utility corporations and gas companies have been built and adjusted to the use of only the best grades of coal. In order to burn lower-grade fuels many such plants must undergo modifications.

Very few districts producing high-class coal are close enough to be of use to consumers in the overcrowded middle and north Atlantic States. Even what coal is available is held in large part by great corporations. Slowly but surely the small consumer is commencing to grasp the situation. He has found that although Kentucky and southern West Virginia contain large supplies of the kind of coal he desires, the freight rates on tonnage from these southern fields are so high that the coals cannot be brought in by rail.

Practically the only available deposits of high-grade steam coal lying within reach of the Philadelphia and New York markets are in Cambria, Indiana and Somerset counties in Pennsylvania. Even in these few districts the undeveloped tracts are limited in area and will be rather difficult to develop, due to the thinness and depth of most of the seams. The situation in regard to gas and byproduct coals is even less favorable so far as the large eastern markets are concerned. West Virginia contains a large supply of these coals, but freight rates again render these southern fields quite inaccessible. Only a few small areas of gas and byproduct coals are available to the New York and Philadelphia markets, and these lie in Pennsylvania.

Each year now witnesses the exhaustion of a number of high-grade coal areas. Far more mines producing better grade coals are being worked out than there are new mines commencing to produce. Many investigators have reached the conclusion that the tonnage of high-grade coal shipped from the low

freight-rate territory into the Atlantic seaboard markets will not be increased beyond its present volume. These authorities expect a decrease in the shipments of such coal and anticipate that the markets will have to be satisfied with a substitute in the way of lower-grade fuel. The only other solution is that consumers will have to pay higher freight rates, thereby bringing in coal from more distant fields.

The coal industry, like every other great business, has developed through a series of stages. Only a few years have passed since there was practically no market for the low-grade coals. Up until recently there has always been an overabundance of fuel. The industry has been the field of bitter competition, with the result that prices have averaged low and profits nil. Furthermore, the consumption of coal in tons per capita has increased much more rapidly than has population. In 1850 the average consumption of soft coal for each person in the United States was only 0.12 ton. In 1880 the consumption had risen to 0.85 ton, while in 1900 it was 2.8 tons per capita. In 1910 the consumption had grown to 4.56 tons, while last year it had increased to 5.61 tons for each inhabitant.

It has only been a few years since the great markets in the vicinity of New York and Philadelphia were supplied with a splendid quality of coal which came from the Moshannon seam in Clearfield County, Pennsylvania. Now this famous bed is practically exhausted. A similar fate awaits the "Big Vein" in the Georges Creek region of Maryland. Forty per cent. of the original Connellsville Basin has been worked out. The well-known Irwin gas-coal field is about 70 per cent. gone. The same story may be told of other famous districts. All of this accounts for the fact that the prices of coal lands in all of the eastern fields have increased from two to four-fold during the last 15 years. In 1900 it was possible to lease a tract of high-grade coal by agreeing to pay a royalty of 10c. per ton. The same lease today would carry with it a royalty of from 20 to 40c. a ton.

Foreign Consumers Demand the Best

A further factor of great importance is the matter of enlarged coal exports. Combinations of strong interests are planning to materially increase our overseas shipments. The coals that will be included in such exports will come from our high-grade seams, for the cost of shipping a ton of coal averaging 12,000 B.t.u. is no less than the cost of shipping a coal running 14,000 or 15,000 B.t.u. Foreign consumers will demand the best we can give them, and this additional business is certain to further increase the scarcity of our best steam and gas coals. Another competitor of the domestic steam-coal consumer will be our enlarged mercantile marine.

Prior to the war Pennsylvania producers complained bitterly of the competition in New England of West Virginia operators. Such complaints have practically ceased. One of the dangers today is that freight rates from Virginia on water shipments are likely to be so high for the next few years that it will be necessary for consumers in New England to try and draw some of the high-grade coal they require from the limited Pennsylvania output.

In the matter of coal control the situation is far more stable than ever before. Only a few years ago there were from ten to fifty independent companies operating in each important coal district. Today the bulk of all the available steam coal in the East is in the hands of eleven companies. Four-fifths of the production of gas and coking coals is likewise controlled by fourteen large corporations. As for coke itself, 60 per cent. of the output in 1918 was produced by steel companies for their own use.

This centralization of ownership and control of our high-grade coal seams will not tend to reduce fuel prices. This fact alone is a boon to the industry and to the Nation, for although it may mean that consumers will pay slightly more to satisfy their fuel requirements, it also insures that mining will be conducted on a less hazardous basis through the installation of safety precautions and less coal will be wasted in the process of mining and marketing the product. In other words, centralization will do away with demoralization, and eventually the benefit will extend to the man who purchases the coal. Centralization has held down the price of anthracite coal and the same will be true in the bituminous situation.

Only One-Eighth of Shipments High Grade

The immense demand for coal during the period of the war brought on investigations that were sadly needed. For the first time in history coal men were obliged to carefully estimate their costs of production. Federal officials acting for the U. S. Fuel Administration made surveys of each and every producing field. This enabled them to classify all of our mines, grouping them according to the grade of coal they produced. These investigations showed more clearly than ever the scarcity of so-called steam and gas coals. In some pools less than 12 per cent. of the total shipments were of high-grade coal.

Coal mining differs from practically all of our other great industries. In farming the producer may bring science to his aid and replenish the fertility of his soil, insuring a continuation of good crops. Even in the matter of lumber it is possible for those engaged in the business to reforest worked-over areas. The coal producer has no such recourse and must be content to see his coal seam disappear for good and all. He must figure that his mine has a life of only 20 or 30 years, and during this time he must secure not only his profit, but regain his initial investment.

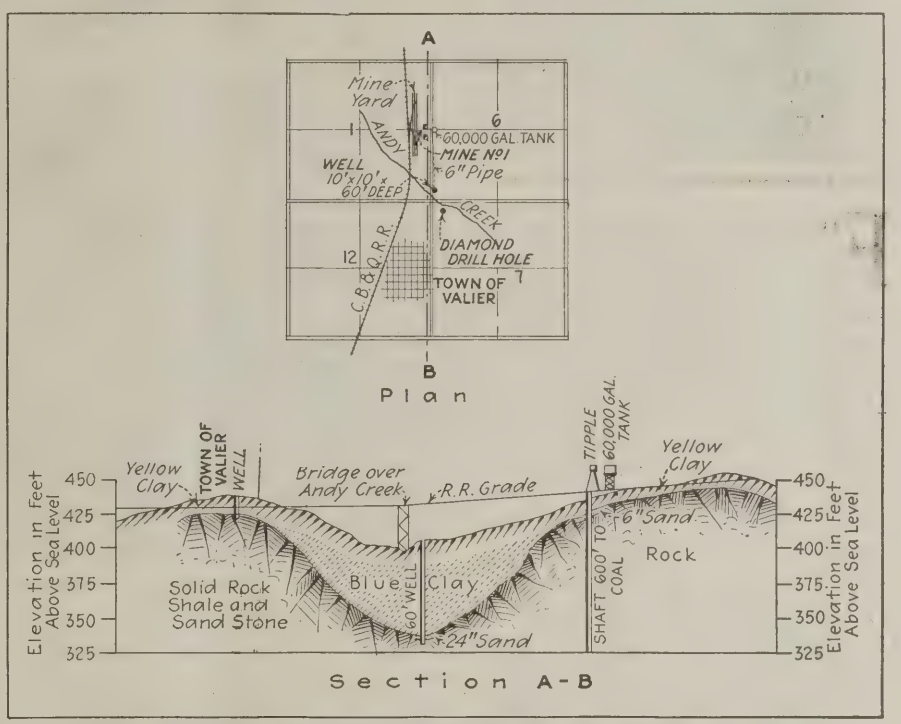
During the last twenty years the population of the United States has increased about 42 per cent. While this growth has taken place the output of coal has increased 172 per cent. The reason is that as civilization advances and mechanical means for doing things increases, the individual citizen has found more and still more uses for fuel. If the same comparative growth continues for 20 more years, the United States will have a population of 139,000,000 people, and the consumption of coal per capita will be approximately 10 tons yearly.

The outcome is plain and inevitable. Irrespective of temporary fluctuations, fuel prices will advance from year to year. What are known now as high-grade coals will disappear entirely. Seams that are now considered unminable will become valuable. Purchasers will buy coal exclusively on the basis of its heat values, and everyone will then understand that coal is not just coal, but that there is a wide difference in the varieties that are produced. Even today coals from West Virginia and Pennsylvania can be hauled by rail to Lake Erie, then shipped by vessel to Duluth and afterward hauled 500 miles inland and be sold successfully in direct competition with coals and lignites produced in the vicinity.

The coal industry is entering a new era, and those who are wise will not mistake the course of events.

Water Supply at Coal Mines

By CARL SCHOLZ
Chicago, Ill.



THE question of water supply at coal mines is an important one. Usually the water found in mines is not suitable for boiler or drinking purposes, and a supply for the operation of steam plants, for the washing of coal, and use in the wash- and changehouse must be obtained from some outside source.

In southern Illinois the water problem is unusually complicated because there are few springs, and the smaller streams cannot be depended upon for a constant supply. Surface reservoirs are subject to many difficulties, principally filling up by silt due to the heavy rains that carry sediment into them. The rate of evaporation, because of the climatic conditions, is high, and unless the watershed supplying the reservoir is properly cleaned and controlled by the coal company, the water becomes badly contaminated and is unfit for boiler purposes. The dams are subject to difficulties from muskrats, and usually a large expenditure is required for the purchase of the necessary land and pipe lines to carry the water to the required point. It has often become necessary for some of the railroads to haul five or six water trains per day during the dry season in order to keep the mines in operation.

In the case of the Valier Coal Co., the water question was carefully studied, even though the plant is operated by purchased electric power. Two sources were considered: First, the usual surface reservoir, a satisfactory site for which was found within a half mile of the mine; the second, a supply from quicksand beds which from the prospect drill holes were known to exist in the near vicinity. The estimates on the surface reservoir indicated an expense of some $30,000 for land, watershed and pipe lines, but to obviate this expense a test drill hole was put down a half mile from the mine where an old drill hole indicated several layers of quicksand about 60 ft. below the surface. In the accompanying illustration the mine is shown in the center of Section 1, the drill hole one-half mile south, and the town of Valier one mile south of the mine. Cross-section *A-B* shows the surface as well as the rock measures, as indicated from the drill hole in the northwest corner of Section 17 and the wells in town, and the shaft record. This shows that in days gone by Andy's Creek, which is now a small stream, eroded a valley nearly a mile wide and 100 ft. deep.

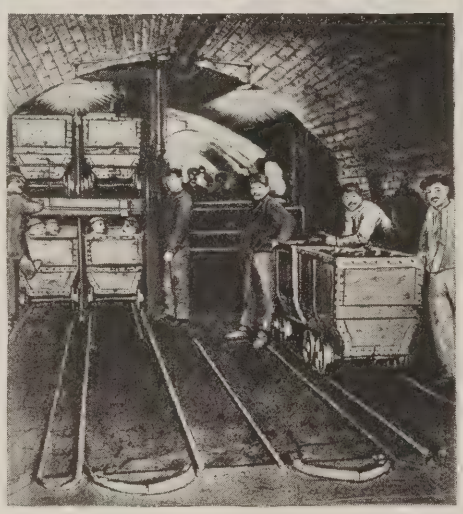
A 6-in. hole was drilled to the 24-in. layer of sand, and upon test this well produced 7 gal. of water per minute. It was estimated that if the size of the hole could be increased the flow would correspondingly become larger; this was proved by sinking a well 10 ft. square from which a supply of over 500,000 gal. of water per day can be obtained without lowering the water more than 50 ft. below the surface. While the well was quite dry until the 24-in. sand was struck, it filled up rapidly, and the water now rises nearly to the surface, indicating that the source of the water must be about as high as the surface is at the well location.

A deep well pump is now being installed so as to pump the water from the bottom of the well. A pressure tank has been erected at the mine on a 75-ft. substructure and a 6-in. cast-iron pipe laid from the well to the tank to insure an ample supply for fire protection and the needs of the washhouse. The maximum requirements of the coal company are about 50,000 gal. per day and the motor-driven pump controlled by a float switch insures the tank being filled to the top at all times.

LOCATION OF MINE, WELL, PIPE LINE AND TOWN OF VALIER

This pressure tank is high enough to also furnish the required head for fire protection to the town of Valier, and it is contemplated to extend the pipe line to the town for the convenience of employees and for fire protection. The pressure tank is connected with the discharge line of the mine pump so that by closing one valve and opening another, water under a 600 ft. head (approximately 250 lb. pressure per square inch) can be supplied to the mine pipe-line system, should it be needed in case of fire.

This simple solution of a vexing problem has suggested this article, which has been written with the hope that it may benefit others as it has this company.



LENS

The Coal Field of France*

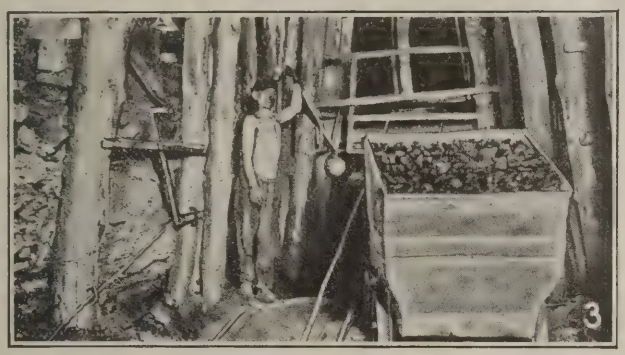
By Frank Haas—Consulting Engineer, Consolidation Coal Co. Fairmont, W.Va.

FRANCE is a proud and thrifty nation. It was her pride, her thrift and her national policy of defense that made her try to develop an independent source of fuel. Unfortunately, her resources in this respect were meager. What coal she had was in small areas widely separated, and these areas were shattered by faults and folds. The struggling industry, when finally established, was besieged by the producers of Germany, Great Britain and the United States. The Germans, on the east, produced the cheaper and perhaps better Westphalian coals. To the north, England (within what is now but a cannon shot of the shores of France) mined and marketed a great variety of coal. On the south, at the doors opening on the Mediterannean coast, the United States was presently knocking. But still the industry thrived, and it was of some magnitude when the war came and all but destroyed it.

One of the principal coal fields is in the Department of Pas de Calais, in northern France. The center of this field is Lens, which was recovered from the Germans during the last months of the war. At that time the newspapers made the public believe that the recovery of this coal field would be a great victory. I anticipated the disappointment when the truth would be learned. Knowing the great constructive skill of the Germans, I could not but imagine that their destructive skill was even greater; and to place such a vulnerable thing as a coal mine in their path meant that destruction would be complete.

Since the recovery engineers have examined these mines and reports have been made. From these we learn that the mines can be unwatered in two years and that normal production can be achieved in five years. These engineers admit that they have seen only the surface devastation, but with deep shafts (some of them through quicksand), with gaseous workings and all main headings driven through solid rock, with thin seams and treacherous roofs, too many opportunities presented themselves to enemies bent on villainous destruction; and in my opinion it will be many more years, perhaps several times five, before Lens and the surrounding basin will again give France its former output of eighteen million tons of coal a year.

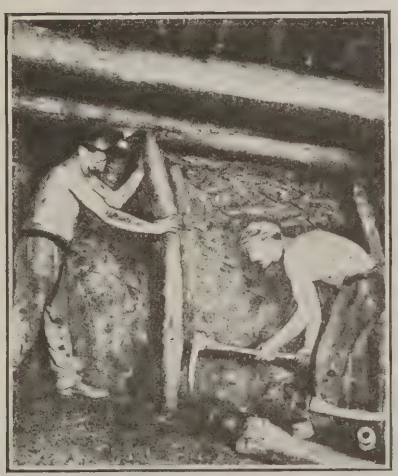
Lens is only a small town, having a population of about 30,000, but it is situated in an important center for iron and steel foundries, engineering works and factories. There is nothing in the town to attract tourists, and outside of the manufacturing and mining activities it is much like many other towns of northern France. The neatness of the cottages and multitude of individual gardens attract particular attention.



The inhabitants have their peculiar habits and apparently follow traditions in the pursuit of their occupations. Labor appears fixed, there being neither influx nor efflux of the population. Evidently "once a miner always a miner," and the son follows the father into the mines. If you flatter yourself that you know some French, don't depend on it in Lens; for you are likely to find that any conversation overheard will be in Flemish and not in French.

Within a few miles of Lens is Liévin, also a mining town, and the location of the experimental station of

*Reprinted from the *Mutual Monthly Magazine*, published by the Consolidation Coal Co. for its employees.



How French Coal Mining at Lens was Conducted Before the German Invasion

Fig. 1—Not much clothes are worn as a temperature of 90 deg. is not unusual. Fig. 2—Coal seams in the Lens region are comparatively thin, 12-in. seams being not at all uncommon. Fig. 3—Mechanical haulage, if any, is by rope usually of endless type with rope running over car. Fig. 4—The seams are nearly all worked longwall, the pitch being heavy and the roof bad; roadways are about 40 ft. apart and the coal is handled several times before it reaches the car. Fig. 5—There are no tracks on the tipple; instead there are iron plates and the cars are shoved around to the various screens and back to the cages, the work being done mostly by women. Fig. 6—Mine entries are usually driven in rock. Fig. 7—Coal from upper seams or heavy pitches is transferred to lower levels by chutes. Fig. 8—Breakfast in the air course at ten in the morning. Fig. 9—French miners are expert timbermen, both from necessity and practice.

that which in France corresponds to our Bureau of Mines. It was here that M. Taffanel worked out scientifically and experimentally most of what we know about coal-dust explosions. This station was built and the force organized shortly after the Courrières mine explosion, in which 1200 miners lost their lives. Previous to this explosion France had a particularly good record for safety, and Lens was for a long time a point of interest to English, German and French mining engineers who went there to investigate French methods.

It was here that the system of "minimum timber" was worked out which was eventually adopted by most of the European countries. This system is a method of cross timbering and is supposed to be carried out in all mine workings whether the conditions require it or not. Additional timber can be added as occasion requires, but the minimum must always be in place. Since the roof conditions in the Lens field are, without exception, bad, some such system is well suited to that region; but it has never been practicable to adopt it here, nor has it ever been so much as recommended in this country.

The average output per man per year underground in the Lens field is about 250 tons, while with us it is more nearly a thousand. The average earnings of a French miner at that time were about $0.90 per day. To describe the mining methods would be a story in itself; but briefly, "longwall" is worked is every conceivable manner, depending on the local conditions.

Courrières mines are within sight of Liévin. This group of mines, about 13 in number, is operated under a concession or lease from the French Government. The mines cover an area of about 13,000 acres, which is more or less completely underlaid by 40 seams of coal of various thicknesses. These vary from semi-anthracite to bituminous coal.

The mining of these various seams was conducted to a depth of about 1200 ft. The shafts are all connected underground, most of them being hoisting shafts. Their total output was about 2½ million tons annually.

The mines were opened in 1850 and the company had a very successful career up to the time of the disaster. Firedamp was not particularly troublesome, and open lights were used almost exclusively. When the mine explosion occurred it was the first large coal mine disaster in France, and as a result there was a lack of organization and of facilities for reëntering the mine after the explosion. Many lives, which prompt and efficient effort might have saved, were lost apparently by suffocation and even by starvation.

France has a normal coal production of about forty million tons and a consumption of about sixty million tons a year. Seventy per cent., or 28 million tons, was produced in the northern part of France forming a part of the area captured by the Germans. The mines in part of this area have, we know, been destroyed. Twenty million tons more coal was consumed than France produced, and the balance was adjusted by coal from England and Germany.

The terms of the peace and more particularly those defining the territory to be returned to France will have a large influence on the available quantity of coal that France will possess after the war. If Alsace and Lorraine go back to France, she will acquire a large active coal territory which is probably undisturbed and a large new and undeveloped territory in Lorraine which has been proved to contain workable coal; but some of it is at a depth of 4000 ft., and it is yet to be determined whether it is possible to mine coal at such a depth.

In spite of this France will face a shortage amounting to thirty or forty million tons of coal for the next ten years. In my opinion the coal industry of France will never entirely recover. It is reasonable to suppose that France will at once enter into an intensive reconstruction period requiring large quantities of coal. This naturally will be largely imported. Certain trade channels for coal will be opened and in time become so thoroughly fortified that it is doubtful whether the domestic supply will be able to replace it.

Outside of man power, coal will be the greatest need of France for the next few years, and on the ability of France to obtain that coal will depend her immediate future progress and recovery. Perhaps the United States can come to her aid. An addition of forty million tons to our annual output is only a trifling matter, and with the large ocean transportation facilities which we have, France may not plead in vain.

Photo copyrighted by Underwood & Underwood

The scarcity of coal was so great in and around Paris during the war that the children, as soon as they got out of school, ran to the coal depots and escorted the carts, anxiously waiting for a lump of coal to roll down from the wagon. They would walk for miles in this manner in order to obtain fuel to feed the kitchen range.

Regarding Longwall

By F. A. POCOCK
Philadelphia, Penn.

SYNOPSIS—*A five-entry system of mining is here proposed, employing longwall faces both advancing and retreating. Longwall conveyors will also be employed. It is the intention in this layout that ten tons of coal shall be produced per man employed. Discussion of the general scheme is invited.*

IN CONSIDERING any method of mine development it is well to observe the worst conditions that may be met. I have concluded therefore to consider the beds of the Freeport and Kittanning series. These are generally under light cover; not over 80 ft. on the average to the surface. They have between them from 30 to 45 ft. of shale, shaly sandstone, and the like—not very strong rock. We may therefore conclude that any longwall system operated in the upper bed, no matter which of these measures happens to be that bed, will force the breaking of the roof rock to the surface and will let the water into the workings.

The rocks in question will not support themselves over any considerable area of worked-out territory. We must therefore look for a system of mining that does not entail the maintenance of expensive packwalls, in order to keep a haulage road open between them. Next there is the fireclay floor which underlies all coal beds of this series, and will cause all kinds of trouble as soon as the water strikes it and the pressure comes on. This will heave and squeeze wherever given an opportunity. Nature objects to voids and fills them as soon as she can. Consequently the best method to pursue is to assist the lady if possible.

With the foregoing facts in view I have designed the accompanying mine plan. Because there are a number of periods in the development of any such extended operation, I have broken this plan up into periods of about six months each, the first break being at the end of the first six months and each succeeding break being six months later. This will save considerable explanation.

Taking up such a development, we will have to start with some basis and see how the whole plan will correlate therewith. In the present case we will make this the cutting capacity, without any reference to haulage or loading. Thus the first limitation will be the cutting speed, "A" in opening the mine, and "B" in producing tonnage to maintain an output for a sufficient time to warrant the cost of equipment. If we are to continue to operate the thin coal beds at a profit despite the increased cost of labor, machinery must take the place of men; and to use machinery we shall have to change some existing methods.

Referring to the accompanying plan a five-entry heading system has been adopted for the main headings. These entries are, say, 20 ft. wide with a 100 ft. pillar between. Let us acknowledge to ourselves that it is wrong, but see if the results will not warrant the radical departure from past and present practice. We will protect these main headings with a pillar of solid coal 300 ft. thick on each side and drive as few connecting stalls as possible, say every 150 ft., as shown.

It is to be remembered that the center entry is the main airway; it may be necessary to use two or three entries as haulage roads, depending on the desired output, while the others are the returns. We must play safe and start right, for 6,700,000 tons of coal must come over these roads during a period of ten years, if we maintain an average output of 3000 tons per day. We propose to recover over 90 per cent. of the total available coal.

Branch headings will be started as shown. Following the five-heading system, but having their cross

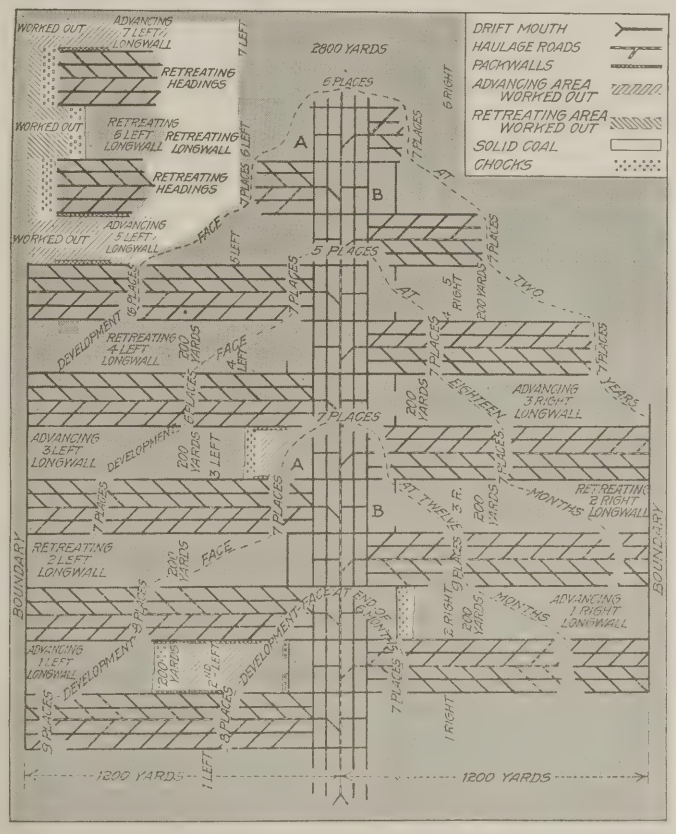


DIAGRAM SHOWING METHOD OF WORKING

headings driven at 45 deg., they will each cover 6600 ft. in width and will be staggered, first to the left and then to the right. There will be a pillar of coal 600 ft. wide left between each of these branch headings; these will be alternately worked as advancing longwall and as retreating longwall faces.

The 1st left longwall advancing will be opened as soon as the outby heading of the 2d left heading has reached the 300-ft. depth of the retaining pillar. Since it is being driven outby, it will be met by a face driven inby from the inby heading of the 1st left headings; when these meet the 1st left advancing longwall face will be in operation. In the same manner the 1st longwall face to the right will later be opened.

The pillar of coal between the 2d and 3d branch head-

ings, both to the left and right, will not be mined until after the advancing longwall panel between the 3d and 4th branch headings has reached the boundary. This alternate system of mining should be persisted in. None of the retreating longwall will be carried into the pillars *A* and *B*, which will be left to protect the main headings until the end of the mining. Now is it possible to get 3000 tons of output per day by any such system, from a 3-ft. seam?

The cutting basis will consist of three items, as follows:

1. That in the main headings. Using an arcwall machine with a 10-ft. cutter bar in five headings, each 20 ft. wide, we have $20 \times 10 \times 3 \times 5 = 3000$ cu.ft., or 110 cu.yd. Allowing a cubic yard to equal one long ton, this will mean 110 tons; and working three shifts per day, this amounts to 330 tons per day. The main headings will thus advance 30 ft. per day or 600 ft. per month of 20 days.

2. That in the branch headings. Here we have an average of eight places, with 20-ft. laterals, so we shall get $20 \times 10 \times 3 \times 8 \times 3 = 13{,}000$ cu.ft. or, roughly, 500 tons per day with an advance of 30 ft. per day.

3. That in the longwall faces. These being 600 ft. long, one cut will give $600 \times 10 \times 3 = 18{,}000$ cu.ft., or 666 tons.

As soon as the longwall advancing faces are opened up it will be advisable to work the cutter one shift in the longwall and two shifts in the branch headings. The first longwall should be opened during the fourth month and the second longwall, that to the right, during the fifth month. The cutting capacity at this time should be about as follows:

	Tons
Main headings	330
1st left branch headings	330
1st right branch headings	330
2d left branch headings	500
2d right branch headings	500
1st left longwall	666
1st right longwall	666
Total	3,322

Thus, by the sixth month we should secure the output aimed at. The 1st left branch headings should reach the boundary at about 18 months, the 2d left headings during the 23d month. The 1st right should reach this limit during the 21st month, and the 2d right about the 25th month. The longwall faces between these could reach the boundary about 30 days later. At this time the 1st left and 1st right branch headings can be opened as retreating longwall faces and be worked back to the pillars *A* and *B*.

From this section we would have taken 800,000 tons of coal. In the meantime the development work of the main and further inby branch headings will have progressed as indicated in the plan, and at a rate that will easily maintain the output at 3000 tons per day.

When, as an illustration, the advancing longwall between the 3d and 4th left has reached the boundary, of course the face between the 1st and 2d left will have been worked out and we can at once begin the retreating work, as shown in the upper left corner of the plan. We have then three faces. There will be about 550 tons per day from each of the headings and 666 tons from the longwall face, making a total of 1766 tons per day, which will be quite cheaply handled.

It will be seen that three-fourths of the branch heading and longwall may be worked retreating, as well as the coal left in the main headings and pillars *A* and *B*, from which 92,000 tons were taken in development work and in which 1,000,000 tons were left.

Packwalls, as shown, are only built on each side of the advancing longwall panels. They are to protect the loading road for a short period and the outlying pillar of each of the branch headings, so that they will not be crushed too much. But as the face of the advancing longwall opens the next lateral to the hauling road, the roof over the worked-out section will be shot down and allowed to pack, so that its weight will be taken off the packwalls to a considerable extent.

The total packwall work for this 6,700,000 tons will only amount to 12,000 lineal yards. Allowing that the walls are 18 ft. wide and 3 ft. high, this will amount to 72,000 cu.yd. Thus the cost for each cubic yard may be charged to 93 tons of coal.

The longwall face and the retreating headings will of course have to be followed up by the usual chock system, to prevent the roof from falling too close to the face. The amount of this chocking will vary in all localities.

The dimensions given in the accompanying diagram are due to the following reasons: (1) The five-heading system, giving an average of eight working places, can be easily cut in 8 hours. (2) The longwall face of 600 ft. both advancing and retreating can be cut across in the same time. (3) By having two conveyors on the longwall and the retreating heading face, each 300 ft. long, which is now possible, the loading of the coal can be reduced to the least possible manpower; and as the men will only have to shovel onto the conveyor, they should easily load 333 tons in 10 hours. Again, this will allow of the longwall coal being handled by two hauling roads at the same time, thus making the handling of the cars easier. In the retreating headings the conveyors will bring the coal to the central haulage road.

The advance of the track along the longwall end can be handled during the time the machine is cutting, and the tracks be ready for the loading; also, the conveyors can be moved up to the broken-down coal as the cutter advances. The haulage is simple, as any one can see, and may be either by locomotives or by rope haulage. The average distance will be 1.6 miles and the longest haul 2.25 miles.

With rope haulage it would mean 100 trips of 30 cars each per day, and as the empties will go in against the loads coming out, a rope speed of 15 miles per hour will suffice. There is ample room on the laterals for this length of trip for the longwall work. The lateral being the siding, the locomotive can bring its empty trip onto this siding, leave it and get the loaded trip from the longwall road, bring it to the siding and back the empties up to the longwall road.

The siding being between the airway and the return, doors at either end will control the ventilation and form the necessary lock for the air. The labor will vary, even in the same thickness of seam, because of varying roof and floor conditions in different localities; but after the longwall faces are opened, the system in my opinion will increase the output to at least 10 tons per man per day, for all men employed where run-off mine is shipped.

I trust that this plan of mining will merit the serious consideration of mining men and that its shortcomings will be discussed in the columns of *Coal Age*.

Annual Meeting of the Southern Appalachian Coal Operators' Association

SPECIAL CORRESPONDENCE

THE Seelbach Hotel, Louisville, Ky., was a veritable beehive of coal men on Feb. 14. About 200 or more operators were gathered there from the various fields of Kentucky, West Virginia, Virginia and Tennessee to attend the annual meeting of the Southern Appalachian Coal Operators' Association and the various group meetings of district organizations. Things were kept lively, owing in part to the fact that the coal operators practically all came from dry territory and struck an oasis in Louisville.

The group meetings were in reality merely get-together or monthly meetings, at which general conditions in the fields, marketing problems, etc., were discussed. About the only business meeting of importance was that of the Southern Appalachian Coal Operators' Association, which held its annual meeting at 11 o'clock, in the Red Room of the Seelbach, there being about 60 or more members present.

Election of officers for the Appalachian operators resulted as follows: President, John L. Boyd, Knoxville; first vice president, W. P. Davis, Knoxville; second vice president, John E. Patton, Chattanooga; third vice president, M. S. Barker, Louisville. J. E. McCoy, secretary-treasurer since the organization was formed in 1909, was renamed by the executive committee, which was composed of the following: E. C. Mahan, Knoxville; C. S. McManus, Fork Ridge, Tenn.; Alex Bonnyman, Knoxville; L. C. Crew, LaFollete; R. L. Stearns, Stearns, Ky.; Lucian Clarke, Nashville; W. P. Young, Nashville; C. W. Henderson, Knoxville. The nominating committee was composed of George M. Camp, Knoxville; C. M. Moore, Careyville, Tenn.; F. F. Floyd, Knoxville; and C. S. McManus, Fork Ridge, Tenn. One of the principal actions taken at the morning session was in connection with the announcement of plans for affiliating with the recently organized Central Coal Association, with headquarters at Cincinnati, a live young organization that intends to compile much excellent statistical information and promises to be of great assistance to the operators south of the Ohio River. Recognizing the fact that under the operation of the existing anti-trust laws the coal operators are greatly hindered in the proper marketing and production of their product, as well as being handicapped in the creation of stable markets for their output, the organization adopted resolutions calling on Congress to investigate the present regulations and to so change the laws as to bring about economic relief. These resolutions were as follows:

PROMINENT COAL MEN AT THE CONFERENCE
From left to right—J. E. McCoy, Knoxville; R. C. Tway, Louisville; G. D. Kilgore, Norton; E. R. Clayton, Harlan

Whereas, the exigencies of the war have made apparent the uneconomic provisions of the Sherman anti-trust law and the Clayton Act; and

Whereas, the said acts limit the right of collective economic action in business transactions, and we believe are a detriment to business development and progress, rather than a benefit to the economic well being of the nation, and

Whereas, the Government in many instances, for the reason of expediency has suspended certain provisions of the said acts, during the war, therefore, be it

Resolved, that the Southern Appalachian Coal Operators' Association, in convention assembled, respectfully recommends that Congress make a thorough investigation of the working of the said acts with respect to their economic effect upon industry and commerce, and that such necessary legislation be enacted as will meet the changing conditions of the business world while providing against the abuses sought to be remedied without working injustice and hardship upon legitimate business development.

Secretary McCoy made one of the best reports ever delivered at any coal meeting in the district, covering the activities of the association during the year. The report showed that the organization today represents about 95 per cent. of the productive capacity in its district, and an enrollment of approximately 85 per cent. of the operators. During the year it secured 46 new members, losing but 13—two by failure, two by resignation and nine by expulsion for failure to pay dues and assessments.

The financial report showed receipts of $25,481.49 during the year, plus a balance of $9732.65 as of Jan. 31, 1918, or a total fund of $35,214.14, against which were disbursements of $26,261.11, leaving a cash balance of $8953.03 as of Jan. 31, 1919. Estimated operation costs for the coming year, including salaries of $8500, amount to $20,319, excess resources being figured at somewhat more than $13,000. During the year the organization secured membership in the United States Chamber of Commerce. Monthly meetings were held by the executive committee, at which traffic matters, labor problems, appointment of district fuel administration representatives, etc., were taken up. Quarterly meetings were held by the organization throughout the year, at which various matters were attended to, including appointment of directors for the various sections to work with the National Coal Association. At a session on July 26 the organization opposed the open saloon during the war, and sent in resolutions to President Wilson and the National Coal Association reflecting its attitude.

Receipts for the year as compared with previous years showed a decline of approximately $15,000, due to there being no special assessments and less special work in connection with credit information, which was

not necessary under Government regulation of prices and shipment of coal on a sight-draft basis. This work will again be resumed, as will also an interchange of information or market data. Today the organization is making daily clearings for producers with an annual output of approximately 5,000,000 tons. Members were called upon to submit their production costs in order that costs for the various fields may be worked out, and it was also recommended that a good accountant be secured to represent a joint committee of leading associations in the district, to handle tax matters. The remainder of the session was given over to routine matters, there being nothing of special interest brought out. At the joint session held in the afternoon approximately 200 operators were present, the room being crowded. It was stated that the men present represented organizations controlling between 50,000,000 and 60,000,000 tons of annual production. At this session an interesting talk was delivered by J. D. A. Morrow, general secretary of the National Coal Association, who discussed the general work of the organization during the year, legislative matters, marketing and labor conditions, and the general situation.

L. F. PRATT

Mr. Morrow mentioned the new tax laws and the fact that coal operators are being unjustly taxed out of proportion to other lines. He referred to the coöperation of the coal operators during the war, and the assistance which they gave in bringing the war to a close, and emphasized the coöperation of the United States Railroad Administration with the operators and the Fuel Administration, and the willingness of Director General Hines to assist in bringing the coal trade back to a peace-time basis. Mr. Morrow urged a continuation of the direct shipment of coal, indorsing the stand taken by the Fuel and Railroad Administrations in enforcing this plan. Banishment of cut-throat competition and substitution of open competition was advocated, to replace the type of competition met with before the war.

At 7 o'clock in the evening a joint banquet was held in the Seelbach auditorium, on the tenth floor of the hotel, more than 200 guests being present. Incidentally, the gathering was in a more happy frame of mind, as the weather had turned raw and cold, with a wet driving snow, which encouraged the operators in the belief that there may be some winter weather before the close of the 1918-19 season.

Judge H. B. Lindsay was toastmaster at the banquet, while the principal speaker of the evening was Ex-Governor John Franklin Fort, of New Jersey. Governor Fort discussed the export coal outlook, the conditions abroad and the possibilities in foreign coal markets for American coal. He also referred to the anti-trust laws and the need for changing these laws in order to aid coöperation, better organization of large interests, and better marketing and lower production costs. His talk in part was as follows:

H. B. LINDSAY

It is generally recognized that coal will become one of the most vital factors in determining industrial expansion and the growth of international trade from now on. The coal resources of all the leading coal producing countries of the world, with the exception of the United States, have suffered immeasurable damage during the war. While virtually all the leading coal producing countries of the world show a steady loss in coal output since the beginning of the war, the production of coal in the United States has increased on a large scale. This rapid expansion of the coal producing facilities of the United States, together with the fact that the United States contains the largest known resources of good coal in the world makes this country the logical future source of supply for a large part of the world's coal export trade.

The war has produced a universal dearth of coal for industrial purposes in foreign countries. Conditions surrounding the coal situation in Great Britain and Germany at the present time do not permit of a large exportation of coal. It is quite likely, too, that the coal industries in those countries, which next to the United States were the chief coal-exporting countries of the world, will have enough to do to relieve the domestic coal shortage, and to supply the needs of their domestic industries during the reconstruction period.

That leaves a market of millions of tons of coal which have to be supplied to meet the needs of coal-consuming countries which have insufficient or no domestic coal resources. In 1912 the total coal exports of the chief coal fields of the world amounted to about 180,000,000 tons, including shipments by rail and sea. The world's sea-borne foreign coal trade amounted to approximately 95,000,000 tons in 1912.

Although the United States is by far the largest coal-producing country in the world, we ranked third, before the war, among the leading coal-exporting countries. In 1913 our coal export amounted to 23,007,229 tons, of which Canada alone took over two-thirds.

Since the beginning of the war a great change has taken place in our coal-export situation. The supply of the world's coal markets has shifted. Our exports of bituminous coal to Latin American countries have increased from 441,368 tons in 1913 to 3,152,107 tons in 1918. Our exports of coal to other parts of the world have increased also.

Provided the problem of shipping and of oversea freight will be settled satisfactorily, so that our American coal can be shipped at freight rates which will allow the American exports to compete in foreign markets, a promising future appears to be in store for the coal-export trade of our country. We have a bountiful supply to furnish, the foreign demand for it is constantly increasing, and with our newly established banking and credit facilities in foreign countries, aided by the Webb law and the facilities of our newly created merchant marine, the future position of the United States in the oversea coal markets seems assured.

Our export trade of coke shows a similar steady increase in volume. It has grown from 900,672 tons in 1913 to 1,413,886 tons for the first eleven months of 1918, an increase of a half million tons, and this in spite of the fact that there was a growing demand at home and that avail-

able ship tonnage was restricted and freight rates abnormally high.

There is a strong tendency among business men to remove restrictions against coöperation. The Sherman law of 1890 cannot be claimed to have been a business success. It was and is an innovation in business. Many of the originators and its later sponsors do not now claim it to have been a success. The courts have been compelled to interpolate into the written statute a court construction as to the "rule of reason" to make it workable with any degree of fairness. It has not helped the cause of the capitalist, laborer, dealer or consumer to any discernible extent. Nobody is entirely satisfied either with the act or its effect in operation. It has never restrained a capitalist, nor has it ever helped a laborer, nor benefited any customer in any commodity sold to him.

During the war it has been practically inoperative. If this law had been enforced in its letter, it is doubtful if the war could have been as effectively fought, which the neglect to enforce it permitted to be done.

Shall this country in its business relations permit that act to remain on the statute book as it is and go back to its strict enforcement in all its conditions? Is it not time for Congress to reconsider this whole question of anti-trust legislation? The total disregard of individual needs and of joint individual interests should not be continued.

That combination should be regulated in the public interest is clear. But the control should not be entirely governmental. It should be under mutual arrangements by joint official and individual action. The business men should have the right to confer with the official to see if the two acting jointly cannot agree on the fair thing. No man should be in a position of being a lawbreaker and told he is one, as the first information that he gets as to an error in his way of conducting his business.

Coal Mining in India in 1917

The annual report of G. F. Adams, Chief Inspector of Mines of India, contains statistics and other information of interest about the mines of India for 1917. During the year covered by this report the average number of persons working in and about all the mines of India was 211,881, of whom 133,042 worked underground and 78,839 on the surface. Of this force 131,672 were adult males, 72,770 were adult females and 7,439 were children under 12 years of age. Those employed in coal mines numbered 153,683, which is an increase of 10,224 over the number employed in 1916.

The output of coal was 17,326,384 tons, an increase of 907,302 tons over that of 1916; the average increase during the previous ten years was 730,641 tons. The amount consumed at the mines—1,835,510 tons—was about 10½ per cent. of the total tonnage, comparing closely with conditions existing about the Pennsylvania anthracite mines in this respect. All the better grades of coal were requisitioned by the government for military purposes at definite prices and were given priority as regards transportation. This arrangement gave the inferior grades of coal an unusual advantage, causing such a demand for fuel that mines started up which had not been in operation for years. The output per underground employee for the year was 182 tons, while 113 tons was the individual average output for all employees.

The question of labor was the controlling factor in the production situation in India; with an adequate supply of labor the tonnage could have been materially increased. There was also difficulty in obtaining machinery and supplies, which handicapped development and increased the burdens of the big plants, especially those mining at a great depth. In 1917 there were 175 fatal accidents in all the mines of India; this was an increase of 25 over the record for the previous year. As a result of these accidents, 201 deaths of employees occurred. However, there was no single accident in which a large number of employees lost their lives. Of these accidents 91 were supposed to be nonpreventable and 46 due to the fault of the person killed. The largest increase was owing to falls of rock or coal; such fatalities amounted to 92, which is quite an increase over those of the previous year. Next to falls of roof, haulage accidents (19) caused the largest increase; this compares with 12 from this cause in 1916.

The death rate per 1000 persons employed was 1.06; per million tons of coal hoisted was 9.41—a slight decrease over the average of the preceding five years. Of the 201 persons noted above as killed in all mines, 163 occurred in coal mines; of this number 61 persons were killed by falls of roof, 50 by falls of rib, 16 in shafts and 20 by haulage.

Obviating the Fire Hazard by Building New Structure Around Old One

In the accompanying view is shown the engine house and substation at the Cranberry mine of the Cranberry Fuel Co., McDonald, W. Va. The structure is built of native stone and is thoroughly fireproof, measuring 80 x 43 ft. It is 30 ft. high from the water table. The inside is plastered with lime and cement mortar. Three sides of the new structure came inside of the

VIEW OF NEW FIREPROOF STRUCTURE

old building which occupied the site, while the remaining wall was outside. Due to this the erection of the new building was quite a difficult piece of work. However, at no time during the progress of the work was it necessary to stop hoisting coal, and the power supply was never interrupted. Steel trusses and roof frame now replace the old wooden roof. Part of the old building can be seen in the illustration; but this will be removed in the near future. For many years the old building was a potential fire hazard, but the new structure has largely eliminated the danger from conflagration. T. L. Yon & Co., of Huntington, W. Va., were the contractors and builders.

A REAL OPPORTUNITY for research is offered in connection with pulverized fuel. Ash, slag and clinker are a live problem; to prevent their formation on tubes, checker work and furnace walls is absolutely essential. Methods of combustion and furnace design are of real importance. Scientific analysis of the difference in heat transmission due to radiant fuel and ash in suspension has furnished an opportunity for investigation.

Timbering in English Mines*

Special Correspondence

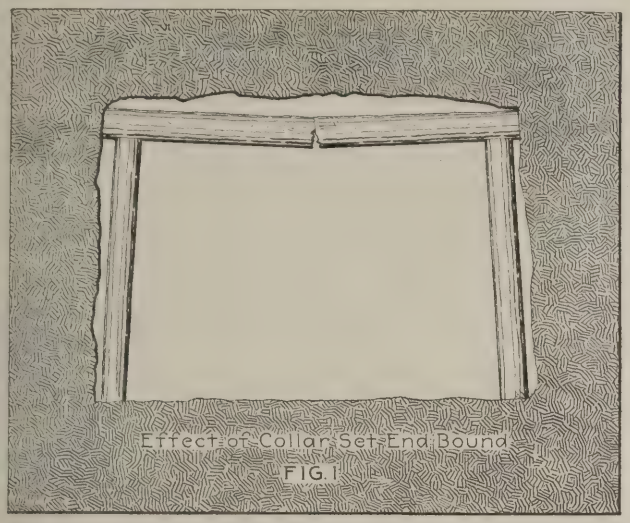
THE question of substitutes for mine timber has long been a subject for the consideration of the English mining engineer, but until the commencement of the war supplies of timber for coal-mine use were both plentiful and moderately cheap so that the matter received no serious consideration. However, when the war started, the question of the supply of mine timber became quite a critical one, owing to the fact that 85 per cent. of the timber used for mine props was imported. The matter assumed a serious aspect and it was thought that some of the mines might have to close down.

Owing to the large supplies of home-grown timber standing in many parts of the country, the scarcity of timber has not been so seriously felt as was at first anticipated. The home-grown timber, while not so good for mine props as Norwegian, has served an admirable purpose. Previously to the war there was a growing demand for timber in European countries, and although immense supplies were to be obtained from Russia, it was a question how long these would last at the rate of depletion. The British Government set aside a certain sum with which to purchase land and to start a number of forests on a large scale. However, this plan has not yet matured, and Great Britain is almost entirely dependent on colonial and foreign supplies of timber. It is therefore essential that the schemes for forestry development should be pressed forward by the Government through all its agencies and landowners, and that forestry associations combine to make it an unqualified success.

Substitutes Have Not Proved Successful

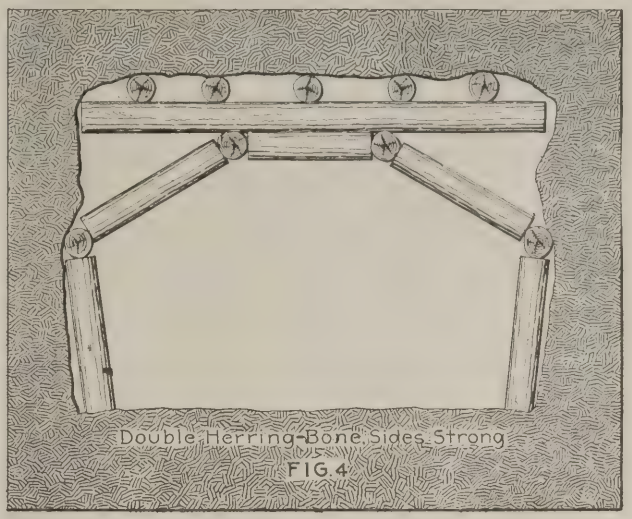
The use of substitutes such as concrete props has been widely discussed, but so far they do not appear to have achieved any great success; they were said to be too rigid, that they split into parts and were difficult to withdraw. The only place where reinforced concrete was thought to be of much service in dispensing with timber was in the area of the shaft bottom and pillar. Mr. Evans suggests that for at least 200 to 300 yards or more on either side of the shaft bottom all main roads should be arched with girders on brick or concrete walls. This would not only save timber but would largely do away with the accumulation of dust where in some cases it is most prevalent. Other substitutes for timber have been tried in the way of steel props and girders.

Wherever timber is used every effort should be made to protect it and preserve it against breakage; this requires strict supervision, modification of present methods and the coöperation of all workmen and more particularly the mine officials. It is undoubtedly a fact that a considerable amount of timber is broken, largely owing to the impracticable method of setting it. In nine cases out of ten if a workman is setting up a collar he will do so without giving any clear space for the side pressure, often putting in a wedge to make it tight; consequently, in a few days the collar breaks in the center and has to be replaced (see Fig. 1). If the official in charge had been sufficiently observant and diligent, he would have prevented this and the collar would have had a much longer life. In other cases the collar may not be made end-tight, but a piece of timber may be wedged in over the center of its length, thereby putting a load at the wrong place. When it is remembered that the carrying capacity of a timber collar depends on the method of loading and that the breaking point may be increased from four to twelve, according to the method of load distribution (Fig. 2), then it is essential that this matter should receive the attention of all mine officials.



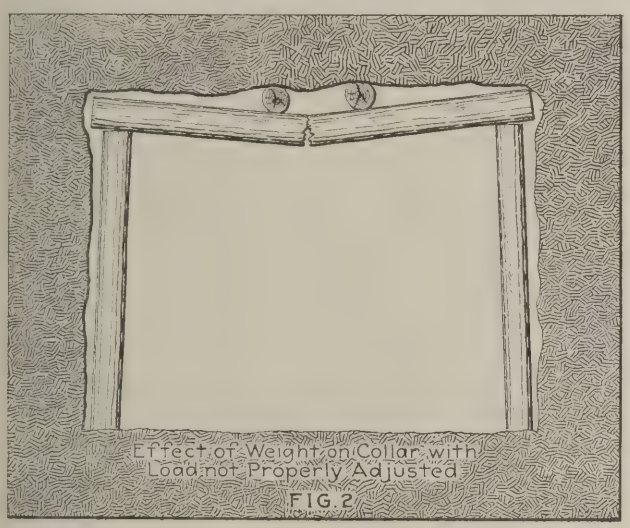
Additional Support for Important Collars

When necessary, additional support should be given to important collars; this can be done to advantage on roadways where there is sufficient height. A method commonly employed to give greater strength to collars at their weakest place is called the herringbone system (Fig. 3). This method also correspondingly strengthens the props which support the ends of the collar. Timber reinforced in this manner has been known to last for years, and although the collar may give way, the herringbone support usually remains intact and sound. If greater strength is required, then a double herringbone system may be adopted; this consists of a short horizontal strut under the middle of the collar with supporting timbers, as shown in Fig. 4. The efficiency of the herringbone method lies in the fact that the struts are short and withstand great pressure; also there are several places which absorb the lateral and vertical pressures.



If the roof and sides are moderately strong the simple method shown in Fig. 5 may be adopted. If the roof is tender then either the double herringbone system may be adopted or collars may be placed, and then be supported as shown in Fig. 6. Previous to the adoption of the herringbone system steel girders were often used on the roadways and cross roads of longwall workings; but owing to the pressure these had to be frequently renewed or reset on account of becoming bent and twisted before the face had advanced many yards. The steel girders, however, are said to be preferable to the timber collars as they can be straightened and used over and over again. The herringbone system of timbering in the roadways has been extremely successful in the mines of Great Britain, both from an efficient and an economical point of view, as practically little new timber is required for long periods.

The question of substitutes for timber will now undoubtedly have to be seriously considered, as the demand for timber will be so great for buildings, for use in connection with railways, about mines and for other purposes that there will be little prospect of the supply being adequate or prices being much reduced. The use of steel props at the face has not received the con-



*Abstract of a paper by S. Evans read at a meeting of the National Association of Colliery Managers of Great Britain.

Good and Bad Methods of Timbering in Longwall Workings

Scarcity of timber in Great Britain necessitates conservation methods and the use of substitutes wherever practicable. Steel and concrete find increased application in roof support

sideration which it merits, probably due to a certain amount of prejudice of both managers and workmen. Some collieries have made attempts to use them and, for some reason, mainly owing to loss from their being buried and from their initial cost, have abandoned the idea as being impracticable. Other collieries have given them a thorough test and have found them to be satisfactory from all points of view.

After 20 years' experience with the continued and extensive use of steel props, Mr. Evans has proved them to be of great service and especially desirable from an economic point of view. They resist a much greater pressure than wood and can be used, after being straightened, for many years; in fact unless they are broken, they have almost an unlimited life. They are quite as safe as wood, are as easily set and are more easily drawn. The loss through breakage and from falls is small, and the cost per ton of output bears no comparison with wood, especially if both top and bottom are strong.

Steel Unsuitable Support for Tender Roof

It has been said that in the case of tender roof, steel is most unsuitable for support as it permits the roof to break around it; but this objection can be overcome by using a fairly large cap piece on top of the prop, thus distributing the weight over a larger area. Similarly, a footpiece is placed under the lower end of the prop. It may be found that, at least for the next few years, the initial cost of steel will not be much higher than timber. and consequently the use of steel props may be more universally adopted as they are considered the best substitute available. In order to give a longer life to wood collars some managers in Great Britain are making use of their old haulage ropes. The collar is flattened on two sides, much the same as a railroad tie, and then several coils of wire rope are passed longitudinally around the collar, as shown in Fig. 7. These ropes are secured in position by nails or staples, and afterward a wooden wedge is driven between the ropes and the collar at each end to keep the ropes tight. Although the timber may break, it is reasonably safe, as it is held by the coils of rope. This method is said, by those who have used it, to be quite effective.

As the softer woods (those commonly used for mine timbers) of Great Britain become exhausted it may be necessary to use the harder varieties. These latter woods are generally unsuitable for props but may be used at the longwall face as supports for the top on the gob side; such supports have been used many times before being of no further use. In such timbering the bottom front piece of timber is placed parallel to the face and bedded on slack, but no corresponding piece of timber is placed on the back side of the crib at the bottom. The wood pack is therefore more easily withdrawn. This is done by taking out the slack from under the bottom frontpiece and then shoveling out the remainder of the slack. If the wood cribs are sufficiently close, little of the timber is lost by falls in the gob.

The timbering at the face just described is able to stand a tremendous pressure and, as it can be made to cover large area of roof, often prevents the top from breaking down. Mr. Evans believes that if this system of timbering faces could be generally adopted a great saving of timber could be effected. Careful consideration should be given not only to the setting of timber but also to its withdrawal. It is now compulsory on the part of certain mine officials to examine all roof from which timber has to be withdrawn, and this duty should be most regularly and consistently observed.

Timber allowed to remain too long in a gob not only becomes a source of destruction but of danger, and it should be imperative on all officials to see that rock packs are made up without unnecessary delay and that all timber is withdrawn as the face advances. In this way numerous props may be prevented from breaking and be used over again. The suggestion is made that in all large collieries there be a special official whose duties shall be confined to the oversight of timbering generally; he shall see that props are withdrawn without delay so as to prevent waste and loss so far as possible. He shall make a daily report as to all timber which is either being buried or not withdrawn. Props left at the side of packs in roadways after the packs have been made up serve no useful purpose and frequently do harm; these props should be taken out so as to allow the gradual subsidence of the roof on the pack. No props should be buried in a pack unless it is absolutely dangerous to remove them.

Props Should be Carefully Tapered

It is the opinion that all props should be tapered before being sent into the mine, but this is of little use unless the work is properly done. If a prop is 6 in. in diameter and say 5½ to 6 ft. long, it should have at least a 10- to 12-in. taper and a portion not more than 3 in. in diameter at the tapered end. Unless this is done properly the prop tends to break as before. For the prevention of waste a face should be advanced as quickly as possible and worked at least 16 hours out of the 24. This means not only that much timber is saved at the face, but also in the roadways and crossways; consequently, the repairs to such roads are reduced by at least 50 per cent. as compared with a face moving slowly.

The question of having as great a length of face as possible between roadways has in a great many cases received preference, owing to the cost of brushing top and for maintenance of roads; in most cases this has been done at the expense of the timber used. Now that timber is so expensive, and may become quite scarce in the near future, it is considered questionable if this policy should be pursued. The timber cost at most collieries now far exceeds the expense of brushing top and repairing roadways; and Mr. Evans urges that the length of face between roadways be reduced, provided a saving of timber can be effected thereby, even if the repairs to roadways are increased. All faces should be kept as straight as possible and be advanced regularly so that no sections extend back into the gob; in the latter case a greater length of face has to be supported and the regular subsidence of the roof is interfered with—it tends not to break at regular intervals. The roof at a longwall face often proves to be bad and requires more timber if the face is not kept straight.

Packs should be of sufficient width and well built—stowed as tight as possible—as these are the only supports on which a roof should rest. If peaks are improperly built or are not of sufficient width, the weight must settle on the timber, often causing it to break.

In the discussion following the reading of Mr. Evans' paper the idea was expressed that to get a good pack it should be built of rock and timber be done away with altogether. Others knew from experience that it was not always possible to do without timber cribs at the face.

Cribs are sometimes very essential, as there may be tender roof in some parts of a mine and not in others. Mr. Evans called attention to the fact that he had not recommended the use of timber cribs, although he considered that there were circumstances in which they were not only an advantage but were almost essential.

The idea that Mr. Evans intended to convey was that in the future, when props would be more difficult to obtain, that it might be necessary to use hardwood cribs at the working face as a substitute for props. He agreed that if an abundance of good material was available for rock packs then it was not desirable to use too many timber cribs, especially in longwall workings, as they might be an impediment to the complete subsidence of the roof.

Some illustrations were given of new systems of pointing props (see Fig. 8). The method at the left of the illustration gave good results and the one to the right even better results; both systems have recently been demonstrated in practice as cheap and effecting a reduction in the number of props used—the props were 5½ ft. long.

One of the War's Heroes

Col. G. A. Burrell has, during the war, had charge of the chemical-warfare research work for both War and Navy Departments. He had full charge of the investigations preliminary to the manufacture of toxic gases, gas masks, smoke screens, incendiary bombs, gas shell, etc. A staff of 1900 people were engaged in the work, which thus formed the largest research organization in the world. The work started in the United States Bureau of Mines and was carried on by that organization until July 1 of this year, when it was transferred to the War Department to become a part of the newly organized Chemical-Warfare Service. Now that the war is over, Colonel Burrell will return to Pittsburgh to resume, by the way, his consulting engineering practice, which covers oil and gas problems, mining problems and chemical-engineering work in general.

Colonel Burrell states that the gas masks finally developed for the American soldier were the best in the world. Prior to the close of the war toxic gases made in America were being used in France and when the war ended more were on their way to France. Authorities fully expected that one of the gases being manufactured would be more effective than any hitherto used. Huge gas-mask and toxic-gas plants which embodied some of the greatest developments in chemical engineering during the war were put in operation in this country. Gas masks were the first American-made equipment for the American soldier to arrive in France. Every American soldier had a gas mask of American make, and at the time of the signing of the armistice the United States was making more toxic gases than either France or England. Col. Bradley Dewey had charge of the manufacture of gas masks and Col. William H. Walker of the manufacture of gas.

The toxic-gas manufacturing industry is dangerous from first to last, whether we consider the experimentation or the strictly manufacturing end of the business. A large degree of real heroism was demanded daily of those who undertook this important work.

Minecdotes

A Little Matter of Annealing

Rolling in his mouth a cud of tobacco large enough to knock a gin cat's eye out at forty rods, "Scotty," the pit boss, began:

"Boys, I used to be the derndest kidder that ever lived; but I was cured, and suddenly at that. It was like this: One of the crossheads of the duplex hoisting engine needed rebabbitting. About this time we got a new fireman in the boiler house, and this chap possessed more ambition than experience. One Sunday the hoister took out the crosshead and told the fireman that he could take it over to the drill press in the blacksmith shop and drill a few more anchor holes in it. I happened to be within hearing distance at the time, so I slips over to the shop and crosses the belt on the drill press. When the drill was started it turned backward and would not cut. The fireman never noticed this. I just casually happened into the shop again, and in answer to his question, I told him that the crosshead was too hard and that he would have to anneal it in the forge fire. No sooner said than done. Pretty soon the hoister came over to the shop, and you can bet that he was not long in getting things straightened out.

"Things run on for quite a while. Finally, cold weather set in, and it was necessary to run steam in the hoisting shaft to keep it free of ice. The steam made it very foggy on the bottom, and it was practically impossible to see anything. One day the mine was idle and I had a bunch of tracklayers over on 3d East, laying some new motor road. I had to come out for my dinner, so along about noon, when I came to the bottom, I never thought and gave the hoister three bells. In a minute I received the answering bell, so I gave him one to hoist away. Boys, what did I do? Nothing; only I stepped into five feet of ice water in the sump at the bottom of the shaft. I thought all the time that the cage was on the bottom. Well, I finally got outside, but I was dern near frozen. I started in to give the Hoister Billy h—, but he just grinned. After I had finished he said:

" 'Scotty, always remember that a man who gives a joke must be able to receive one in turn. When you signaled I knew your whistle, so I decided to just give you an "annealing." The fireman requested it.' "

Legality of Joint Sales Agencies

By A. L. H. STREET
Attorney at Law, Minneapolis, Minn.

A COUNTY association of coal operators asks the opinion of *Coal Age* concerning the propriety of forming a pool for the sale of the members' products. "This newly formed association," our correspondent writes, "represents through its membership over one million tons of bituminous coal output per annum. Owing to conditions, these operators are striving to build up a trade without running foul of the law, whereby they can continue to do business. Many of their operations are developed to a point where they are beginning to repay on the investment. A meeting developed that the coal should be pooled and sold through an agency, thereby enabling the broker to fill orders with coal to suit particular requirements of his trade. In this method it is deemed possible to continue to operate the numerous mines of this section, both wagon and tipple."

The matter was referred to Mr. Street for his opinion, which is published below for the benefit of others who are interested in the subject of joint sales agencies.

AN EXAMINATION of the law reports convinces me that the best advice that can be given at long range and in the brief time available for research, is to proceed with extreme caution in the creation of any joint selling agency and to act under the direct assistance of counsel.

So far as I am able to ascertain from a view of the adjudicated cases, arrangements of this kind in the coal industry have been uniformly frowned down by the courts as being violative of the anti-trust laws.

If the plan mentioned by your correspondent will involve a suppression of full competition between the members of the association as to prices or production, it would doubtless be held by the courts to be invalid as being monopolistic. But whether the public interests would be actually so affected as to result in litigation testing the validity of the pooling arrangement is, of course, conjectural. All that can be said is that during our participation in the war the Federal Government has completely reversed its policy of discouraging combinations of producers. As I heard a prominent business man say the other day, the Government has lately *compelled* violation of the anti-trust statutes as a necessary means of efficiently and economically carrying out war measures. How soon it will be before affairs become so far restored toward normality as to cause a revival of agitations for strict enforcement of the anti-trust laws is not presently apparent.

What Courts Have Held

The judicial law of our subject appears to be comprehended by the several Appellate Court decisions reviewed below, all of which it will be noted are unfavorable to the validity of pools or joint selling agencies sought to be maintained by independent producers controlling a considerable portion of the production of a given district.

In the case of Slaughter vs. Thacker Coal and Coke Co., 55 West Virginia Reports, 642, 47 Southeastern Reporter, 247, it appeared that three of the four coal-mining companies operating on the Thacker vein in Mingo County, West Virginia, organized a corporation for the sole purpose of acting as sales agent for the operating companies, the three mining companies holding nearly all the stock. Each of the three mining companies made a separate contract with the agent corporation providing that the latter should act as the producer's exclusive sales agent, and sell at prices uniform as to all three companies. The corporation was to advertise and introduce the mining companies' product in the markets, establish and control sub-agencies, make all sales and collections, and deduct as its compensation certain tonnage commissions.

Supreme Court States Plan Was Invalid

Defendant, one of the three companies, later refused to be further bound by the arrangements, and in subsequent receivership proceedings against the agent corporation, suit was brought to hold defendant liable as for breach of the joint arrangement.

The Supreme Court of Appeals of the state affirmed a decision of the trial judge, holding that the plan was invalid as involving an unlawful restraint of competition. The following extract from the opinion on appeal shows, first, the individual view held by Mr. Justice Poffenbarger, who wrote the opinion, and, second, the views of his associates who overruled him:

It is impossible to see how the public was, or could have been, injured by this contract. Three small companies, out of the vast number of coal-producing companies in this state, entered into it. The quantity of coal put upon the market by them is an utterly insignificant portion of the vast quantities thrown upon the market by the numerous competing producers. In the absence of some great combination, virtually controlling the production and price of a commodity in the country, the price is regulated and determined by the law of supply and demand. It is manifest that, by this agreement, the production of these three mines was facilitated and increased rather than stifled or curtailed. . . . The validity of this contract must be determined by its practical effect rather than by ascertaining whether it falls within the terms of a legal definition. Contracts in restraint of trade and contracts eliminating competition, as a general proposition, are illegal and void on the ground of public policy. But it is, nevertheless, true that there are numerous contracts which all the courts hold good and which, at the same time, tend, in some degree, to restrain trade and stifle competition. . . .

Upon this view of the contract, my inclination is to hold it legal, but my associates are of a different opinion. Applying the principles hereinafter stated, they consider it void, as against public policy.

". . . The true test of the illegality of the combination being the injury to the public, and whether its necessary consequence is to control prices, limit production, or suppress competition in such way as to restrain trade and create a monopoly. To render the combination illegal on this ground, it is not necessary that evil intent or actual injury be shown, but it is sufficient to know that the inevitable tendency of the act is injurious to the public. . . .

"In some way several corporations competing in production merge into one, and cease competitive production. By means of large capital this new corporation can produce largely, or limit production, lessen supply, enhance prices, and lower the prices of materials used in production."

In the later case of Pocahontas Coke Co. vs. Powhatan Coal and Coke Co., 60 West Virginia Reports,

508, 56 Southeastern Reporter, 478, a similar arrangement for sale of coke produced by about twenty different manufacturers was held to be void, although the purpose of the plan, as stated in the formal contracts, was "to improve conditions in the manufacture, inspection and shipment of coke, and to improve and regulate the quality of coke manufactured in the district."

"We are clearly of the opinion," said the Supreme Court of Appeals, "that it was not necessary, in order to arrange for the improvement of conditions in the manufacture, inspection and shipment of coke . . . for the said corporations to form a trust or combination, the direct effect of which is to destroy all competition among them, to pool their production and to cause them to enter the market for the sale of their combined production as a single concern and which tends to restrain competition between them and others engaged in the same business."

The Pennsylvania Supreme Court adopted about the same line of reasoning in the case of Morris Run Coal Co. vs. Barclay Coal Co., 68 Pennsylvania Reports, 173. In this case it was shown that five coal companies controlling two regions agreed to appoint a committee to take charge of their interests and appoint a general agent. Each producer was to make deliveries on orders of the committee and on the terms and at the prices fixed by the committee.

Responding to a claim that the arrangement was designed "to lessen expenses, to advance the quality of the coal, and to deliver it in the markets it was to supply, in the best order, to the consumer," the Supreme Court said:

It does not follow that these advantages redeem the contract from the obnoxious effects so strikingly presented by the referee. The important fact is that these companies control this immense coal field; that it is the great source of supply of bituminous coal to the State of New York and large territories westward; that by this contract they control the price of coal in this extensive market, and make it bring sums it would not command if left to the natural laws of trade; that it concerns an article of prime necessity for many uses; that its operation is general in this large region, and affects all who use coal as a fuel; and this is accomplished by a combination of all the companies engaged in this branch of business in the large region where they operate. The combination is wide in scope, general in its influence, and injurious in effects. These being its features, the contract is against public policy, illegal, and therefore void.

Another case in which a coal-pooling arrangement was held to be illegal was United States vs. Chesapeake and Ohio Fuel Co., 115 Federal Reporter, 610, decided by the United States Circuit Court of Appeals. Three individual, three partnership and eight corporate operators bound themselves for five years to deliver all their output to the defendant fuel company. A committee of the operators fixed prices at which the coal should be sold to the fuel company. The company was bound to pay over to the operators the excess of profits on resales above a certain percentage compensating the fuel company. As the contract involved interstate commerce and was found to illegally restrain competition, it was held to violate the Federal anti-trust act.

And it will be remembered that the United States Supreme Court, in 1912, decided in the case of United States vs. Reading Co., 226 United States Reports, 324, that a series of identical contracts between interstate carriers with a great majority of independent coal operators to market all the product of the latter at an agreed percentage of tidewater price, constituting a scheme to control the sale of coal, violated the Sherman Act.

Legal Department

Operation of Company Stores—A merchant has no standing in law to complain of the maintenance by the owner of coke works of a store at which the employees of the works are required to buy their supplies as a condition upon the continuance of their employment; there being no showing that the owner of the coke works was actuated by malice against the complaining merchant in establishing the company store. (Dagostino vs. Rogers, 68 Pennsylvania Superior Court Reports, 284.)

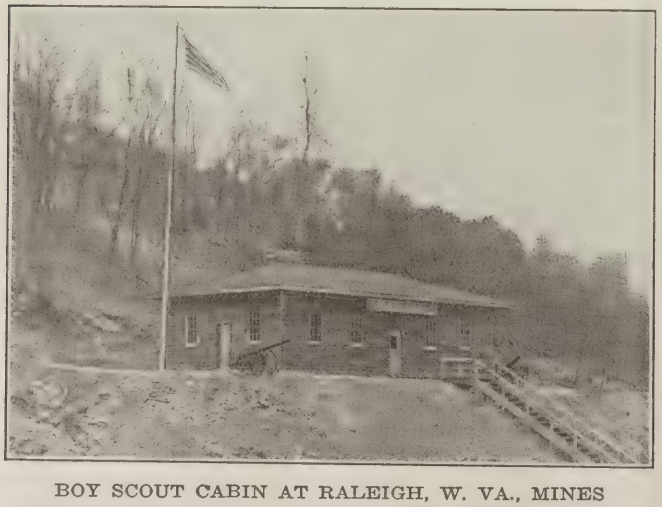
Injury to Adjoining Property by Mine Drainage—Discharge of mine water, either by drift or from a lower level by a shaft, does not impose liability upon a coal-mine owner for resulting injury to adjacent property if the injury is not negligently or maliciously inflicted. But the burden is on the operator to show that the natural use of his property which causes the injury complained of is unavoidable except by an expenditure which would substantially deprive him of the use of his property. (Clouse vs. Crow, 68 Pennsylvania Superior Court Reports, 248.)

Employment of Minors—A Pennsylvania coal operator who employs a boy in a mine, he being under the age limit fixed by statute for such work, is liable for accidental death of the minor in the employment, regardless of whether the accident be attributable to negligence of the operator. Nor are the parents to be precluded from recovering damages because the father knew the work the boy was doing, and the mother received the wages, if they did not know the boy's exact age until after his death. (Telinko vs. Pittsburgh Coal Co., 68 Pennsylvania Superior Court Reports, 143.)

Injunctions Against Unlawful Strike Measures—In 1907, a coal company obtained an injunction against certain unlawful interferences with the company's business in an attempt of the defendants to unionize the mines of the corporation. The injunction was directed, also, to "all other persons whatsoever who may have acquired notice, information, or knowledge of the judgment," etc. It is held by the United States Circuit Court of Appeals, Sixth Circuit, that this decree did not bind persons who were not parties to the suit, and who ten years later took part in another and unrelated strike, although members of the same labor union involved in the first strike. (West Kentucky Coal Co. vs. Tosh, 252 Federal Reporter, 44.)

Liability for Malicious Prosecution—Affirming a judgment against defendant, awarding damages in favor of plaintiff, for malicious prosecution, instituted by an employee of a detective agency engaged in looking after defendant's interests, it is held by the Virginia Supreme Court of Appeals that to sustain such an action it must be shown that the prosecution was instituted by defendant, and has terminated favorably to plaintiff, that it was instituted without probable cause and with malice. A private detective working for a coal-mining company, and subject to its control, is an "employee" of the company in the sense that the company is liable for malicious prosecution set on foot by him in the course of his work for the company, although he may have been paid for his services by a detective agency which assigned him to the work under the agency's contract with the mining company. It is a good defense to an action of this kind that the defendant acted in good faith and in reliance upon legal advice in starting the prosecution. (Redd vs. Clinchfield Coal Corporation, 96 Southeastern Reporter, 836.)

DEPARTMENT OF HUMAN INTEREST



President Wilson Recognizes Loyal Help of Raleigh Boy Scouts

The Boy Scouts of Raleigh, W. Va., like the other bodies of that up-to-date mining town, is a thriving institution. *Coal Age* has already spoken of the Virginia theater erected by the Raleigh Coal and Coke Co. and of the large number of automobiles that are owned by the employees of the same company (see *Coal Age*, Vol. 9, page 977). The employees of the company have also a mining institute and several bands (see *Coal Age*, Vol. 9, pp. 680 and 681). In earlier years the Boy Scouts formed a less imposing feature of the village, but when the war occurred it gave the boys an opportunity to show their spirit.

During the canvass for the Third Liberty Loan the boys of Raleigh Troop No. 2 were extremely active, and as a reward they succeeded in securing the American flag which was offered in every state by President Wilson to the Boy Scout troop which performed the largest service. They have the flag in a glass case at their troop cabin. It measures 5 x 8 ft. and is of pure silk bordered with a gold fringe. It has a silk cord and tassel. There is also a leather socket and belt for carrying the flag.

A broad silver band at a joint in the staff has the following inscription: "Presented by the President of the United States of America to Raleigh Troop No. 2 of West Raleigh, W. Va., for distinguished service in the Third Liberty Loan of April, 1918, for State of West Virginia."

The work of the troop was no less remarkable when it undertook the sale of the bonds of the Fourth Liberty

BOY SCOUT CABIN AT RALEIGH, W. VA., MINES

Loan. The boys placed three large subscription clocks in conspicuous places in Raleigh and moved the hands of these clocks daily so that they registered the progress of the drive. One clock showed what was being subscribed by the white people and another the bond purchases of the colored people. A third showed the pledges of the whole people, white and colored. At the close of the campaign the total subscription was found to be $53,250. Of this the white people subscribed $28,000 and the colored people $25,250.

Taking into consideration the fact that the majority of the colored citizens have been at Raleigh less than a year, this subscription by the colored people demon-

BOYS WHO WON PRESIDENT WILSON'S TROPHY

strates that they were equally interested in the great fight for democracy, 135 of them having subscribed this magnificent sum. These good fellows did not stop at the lowest loan procurable, for their subscription averaged, as a little calculation will show, $187.04 per person.

Consolidation Coal Co.'s Subscription to the Fourth Liberty Loan

The employees of the Consolidation Coal Co. subscribed $728,950 to the Fourth Liberty Loan. The Maryland division subscribed $62,500; the West Virginia division, $294,000; the Pennsylvania division, $140,000; the Elkhorn division, $151,200; the Millers Creek division, $55,650, and the Baltimore office, $25,600.

The officials of the company also purchased large amounts, the largest sum subscribed being $105,000. These purchases by officials brought the total subscriptions above the million-dollar mark. In addition to this the company, as a company, bought a million dollars of the loan, making a total for employees, officials and the company of over two million dollars.

The employees subscribed $498,950 more to the fourth loan than to the first, $455,950 more than to the second and $200,100 more than to the third. In all they have subscribed $1,761,700 to the four loans. Each loan has shown an increase, though the ranks were thinned by 12 per cent. of the men entering military service. There are 1282 stars on its service flag, and in its January issue of the *Monthly Magazine* the company had regretfully to record that eight men had made the supreme sacrifice and given up their lives in the service of their much-beloved country.

Director General Hines Sheds Light on Railroad Fuel

With 80 per cent. of its coal requirements covered by existing contracts, the Director General of Railroads has announced that it will be impossible to effect much greater distribution of orders unless operators holding contracts will be willing to abrogate them for the general good. With regard to the matter of better distribution of coal purchases which have been insisted upon by the National Coal Association and by representatives of the United Mine Workers, the Director General said:

Only about one-fourth or a little more of the total bituminous coal production is consumed by the railroads. To a very large extent the mines whose output can actually be used for railroad purposes is restricted on account of the quality of coal needed. A further important point is that at the request and, indeed, at the insistence of the Fuel Administration the Railroad Administration has made contracts for a large part of its coal with the result that only about 20 per cent. of the coal used by the Railroad Administration is not covered by contract. Naturally the contract coal cannot be modified except with the consent of the operators.

The only other possibility that occurs to me is that if the operators with whom we have made contracts for about 80 per cent. of the coal are willing to release us from those contracts, we will be glad to distribute that coal among the various mines which can produce the necessary quality of coal and which will be willing to sell at the same prices we have under the contracts.

Some time ago our attention was called to the fact that there was a concentration of orders for the Railroad Administration in certain fields so as to leave other fields without orders. We promptly met this situation by giving instructions that coal should be bought as far as possible by each railroad on its own railroad.

With regard to giving publicity to bids the Director General has ordered that "any prices which are established will be available to representatives of the miners or others who may be interested and who may request the information, both as to prices and as to the names of the sellers."

So as to be clear of any charge of trying to force down wages, the Director General has provided that purchasing agents must not suggest any prices to operators and must stipulate that purchases are to be based on existing wages.

After promising that withdrawal of coal from storage would be diminshed, Director General Hines said:

The very large amount of storage coal which the railroads have accumulated was accumulated at the request of the Fuel Administration, and while we are endeavoring to use this storage coal in such a way as not to embarrass the situation, the fact remains that the coal is there and must be consumed.

The National Coal Association, which has been one of the principal parties to the controversy, accepts the ruling of the Director General as satisfactory. The Association has been contending that all bids should be opened at a given time and place in the presence of the coal operators interested. It is regarded as very likely that the Railroad Administration will go a step further and allow that procedure to be adopted. J. D. A. Morrow, the secretary of the National Coal Association, is outspoken in his commendation of the spirit of fair play which has actuated the Railroad Administration officials, throughout the entire discussion.

Pooling of Freight Equipment Proved To Be a Good Measure

Pooling of freight equipment has been accompanied by such success as to make a return to the old methods of car distribution unthinkable. This opinion was expressed by E. H. Degroot, Jr., assistant manager of the car-service section of the Railroad Administration. He expands his thought in this connection as follows:

So far as the work of the car service section is concerned, it should be possible to forecast the future with some degree of accuracy. For example, the common use of freight equipment under centralized control has proved so successful that a return to the old individualistic methods of car distribution is unthinkable, and the car service section or some other agency with plenary powers will undoubtedly have to continue to supervise and control the relocation of freight cars indefinitely.

Many of the responsibilities of the commission on car service in the days before the United States entered the war, and prior to the creation of such war organizations as the Fuel Administration, Food Administration, War Industries Board, etc., bid fair to become again problems of the car service section with the passing of those organizations, and as the transportation requirements of the post-war period of reconstruction develop. In short, for the car service section, the signing of the armistice promises to change the form of some of the questions which must be answered and to superimpose others which cannot be disposed of within any definite period which it is now possible to foresee.

Now I believe that one thought which your president had in mind when he said, "We want to keep the good things that have been developed," was that you would want to have a share in further developing these things in the days to come, and so I shall close with a few brief suggestions along that line. As shippers you can help by (a) ordering cars only as actually required; (b) loading them promptly; (c) loading them to journal or to cubical capacity, as the case may be; (d) tendering shipping instructions early;

(e) billing the freight (as far as is possible) direct to destination and to the final consignee; and (f) transmitting bills of lading promptly for all order shipments, making sure that consignees are given necessary information to permit expeditious handling.

As consignees you can contribute to this good work by (a) accepting freight promptly and, when switching orders are necessary, placing them in advance of the arrival of cars if possible, taking up bills of lading without delay in all cases where they are involved; (b) unloading cars as early as possible without taking advantage of free time allowances; and (c) advising agents as soon as cars are released.

Discusses Coal Provisions of the Oil-Land Leasing Bill

While principal interest surrounds the oil features of the so-called oil-land leasing bill, the coal provisions of that measure came in for frequent controversy during the discussion of the conference report in each House of Congress. Senator Pittman, in the course of debate, made the following statements with regard to the coal provision:

The bill provides that any citizen of the United States may acquire either by purchase or by lease not to exceed 2560 acres of coal land. That is the provision. Now, if it is acquired under lease it is acquired under the general provisions of the bill. If it is acquired by purchase he must designate the tract of land, and it must be advertised and published and put up to public competition. After the price and value have been fixed by competitive bidding, then the Secretary of the Interior decides whether he will accept any of the bids or not. If the Secretary of the Interior is honest, then the Government will get the full price of the coal land. But Mr. Pinchot says it will not buy coal lands because people would rather lease them. But if they do buy it, then it is on a value determined by competitive bidding, and even after the price fixed by competitive bidding the Secretary of the Interior can say, "I do not consider that fair to the Government and I will not take it." It all depends on the honesty of your administrative officers, both as to the leasing provisions and as to the sale provisions.

But that is not all. There is not a stockholder in one of the big coal companies in this country who can acquire a lease or title to a foot of coal land under this bill. There is not a man who is interested as a stockholder in any other corporation or as an individual in any other coal in the country in excess of 2560 acres of land who can become a lessee or a purchaser under this bill. Where does your monopoly come from? How can you possibly monopolize 40,000,000 acres of coal land under such a provision? I tell you the object of the bill is to fight the monopoly.

Regulation Suspended on Tidewater Shipments and Reconsignments of Coal

Reconsignments of coal now may be made without restrictions. Operators shipping to tidewater are no longer required to consign their coal to the Tidewater Exchange. A formal order making possible the return to pre-war conditions in the two particulars mentioned above was issued Feb. 22 to become effective Feb. 28. The Fuel Administration calls attention to the fact that voluntary arrangements to operate through the Tidewater Exchange are in no way interfered with by the order.

Exports of fuel during the latter half of 1918, according to the Exports Control Committee, averaged 165,255 tons per month.

Commission from United States to Observe Rehabilitation of French Mines

The Bureau of Mines commission which will spend several months in Europe observing the engineering practice in reopening the destroyed mines of France sailed from New York Feb. 15. The commission consists of George S. Rice, the chief mining engineer of the bureau; F. G. Cottrell, the chief metallurgist, and F. R. Probert, one of the bureau's mining engineers.

Warns Against Use of Army Gas Masks in the Coal Mines

Fearing that returned soldiers will attempt to make use of the army gas masks in coal mines or other places where poison gas may have accumulated, Director Manning of the Bureau of Mines makes the following statement: "The army gas mask should never be used in mines, because of the uncertainty that exists as to the amounts of gases in the atmosphere and the liability of there being insufficient oxygen to support life. Its use in the mines will lead to serious accidents and fatalities."

Toledo, Ohio, has been eliminated as a rate basing point for coal shipments. An order by the Director General of Railroads points out that no coal is produced at Toledo and makes unnecessary the Toledo coal tariff.

Conclusions of the Senate Committee on Manufactures, in regard to the coal situation, will be submitted to the Senate before the close of the session on Mar. 4, it has been announced. A. B. Jessup, Percy Madeira and A. C. Dodson appeared before the committee Feb. 18 to make supplemental statements. Members of the committee are already at work on the report.

Colliery Notes

In general, too much stress is said to be attributed to the advantages of pulverized coal, regardless of its manner of burning, and overlooking the operating difficulties. A wide range of choice is possible in regard to the equipment for drying and pulverizing, as the development of such machinery has been encouraged many years by the cement industry. It is thought that the real problems connected with the use of pulverized fuel are those of properly handling, feeding and burning it.

In a discussion about the smoke produced by byproduct coke ovens, W. H. Blauvelt stated at a recent meeting of the American Institute of Mining Engineers that it was made almost entirely during the time of charging the ovens; at that time the ovens are cut off from the hydraulic main. The amount of smoke that escapes at this time is extremely small compared with the amount produced by a beehive plant; the mechanical difficulties in preventing any escape of smoke at charging time are considerable. However, several devices are in operation at a number of plants which collect most of the smoke made during charging, and several devices are being worked on for its complete elimination. These will probably be employed only where the smoke is objectionable on account of the location of the plants, as the value of the byproducts in this smoke is quite small.

EDITORIALS

Mule Versus Motor

THERE are some who will be sorry to see the original motive power of the coal mine—the old mine mule—disappear. They will, however, be few and far between; and certainly the "skinner" will not be among them. There is little doubt that he will relinquish his mule in favor of the more inanimate but docile motor with a sigh of relief.

The mining reports for the State of Illinois give some interesting statistics showing the decline in the use of animal haulage and the simultaneous increase in motor haulage. In the year 1900 there were 512 mines in which animal haulage was used, and in 1917 there were only 113; electricity was used at only seven mines in 1900, and at an even 200 mines in 1917.

In 1900 the tonnage handled by the mine mule was about fifteen times as great as that handled by the electric motor, and perhaps it was little thought that the former would meet his Waterloo only ten years later. But in 1910 we find that mine motors in Illinois handled 23 million tons of coal as compared with 21 million hauled by mine mule. From this time on the tonnages handled by the two methods have spread rapidly apart, until in 1917 the mine motors are credited with 67 million tons as compared with less than 9½ million tons by animal haulage.

The result in other states, with similar haulage conditions is much the same. No better proof, perhaps, could be put forward of the phenomenal development of mechanical equipment in the mining regions. The handwriting is on the wall, and the operator who fails to put his plant on the most economical operating basis possible will some day find himself facing prohibitive mining costs.

It is to be hoped that the United States will get her full share of international trade, but whether she ranks first, second or even third in the matter of the world's financing is less important than that she make good in her effort to humanize the work of reconstruction and extend throughout the world her disinterested ideals.

New England Seeks Freedom of the Seas

WHILE the Shipping Board diligently plans for a plebiscite to determine the future policy of the American merchant marine, it is much to be hoped it will not overlook the present high freight rates on the Atlantic Seaboard; for the situation is one crying for immediate correction. That the high rates still prevailing on coal shipped northward from Hampton Roads and Baltimore have not had disastrous effects on industrial conditions in Boston has been due to the fact that when the war ended Boston had on hand an abnormally heavy tonnage of coal.

Figuratively speaking, since that time Boston has been leisurely "Fletcherizing" the cud and doing it with more than usual care; for the cud was delivered to Boston at a war figure, and, being bought at a cost higher than Boston had ever paid before, it has been utilized with more than ordinary care. Before the season is far advanced Boston will be looking for fuel and wondering why it cannot be shipped at a lower cost.

It is true there are a number of wood steamers that have been built as a part of the emergency program, and these could be used for the transportation of coal were not these and certain small steel vessels lacking in carrying capacity and so uneconomical in operation. This is generally acknowledged by trade and governmental authorities alike. Such vessels must find their place, if place there be, elsewhere.

What the coastwise people want, and what they must have, are the large steel colliers that were withdrawn for oversea transport last year to meet an actual need. That being the case, a thorough canvass should be made at as early a date as possible to determine what ships of 5000 tons and upward can be restored to the trade, for only such ships can meet the conditions competitively. An 8000-ton ship takes no more officers and only a few more seamen than a 3000-ton ship. Therefore only ships of the large size can transport coal at a low price.

While the war lasted it was imperative to reserve as much space as possible for Government shipments. It was necessary also to maintain coastwise rates at a point high enough to keep neutral vessels, and vessels built at high cost, in operation. The war is now to all intents and purposes over, and with it have largely ended the necessities just detailed. The neutral ships have departed, and the new steamers constructed on the Great Lakes are tied up in Atlantic ports without orders and without even railroad requisitions to keep them going. Despite this change in conditions, rates remain unchanged at the level established in April, 1918.

This posture of shipping matters causes the New England manufacturers much apprehension, as will be seen after a little consideration. As an example, a large power plant has been constructed at tidewater so as to obtain cheaply transported fuel. It has established business inland on the ground of cheapness of the water-borne fuel with which the power plant is provided.

Today the lowest rate by steamer is $3.65 from Baltimore or approximately $5.50 from the mines. The all-rail rate from central Pennsylvania is $3.75. Thus there is a differential of $1.75 per gross ton, right at the tidewater destination. This tidewater plant has power sold inland to stations where rail coal is easily accessible. Fortunately, each contract for power has a coal clause so that the extra cost of water-borne coal falls on the inland user as well as on the plants nearer tidewater. But the high cost of power is giving the client much

dissatisfaction. He feels that with rail-borne coal he could produce the current himself at less cost than he can buy it of the concern with which he has a contract. In any event, the tidewater power plant has not the advantage it sought in establishing itself along the coast.

Steamers owned by coal shippers are actually tied up because the rate of freight set by the Shipping Board is not merely a maximum rate, as was the price of coal recently set by the Government, but a mandatory rate, not to be deviated from upward or downward, and applicable to all steamers requisitioned by the Board in 1917; namely, to all those being of 2500 tons deadweight and upward.

This classification covers practically every steamer in the coastwise coal trade, so not a single shipowner is free to charter his boat at a penny less than the mandatory rate. Not only is this true, but furthermore a big tonnage has been operated largely through an office maintained by the Emergency Fleet Corporation. Barge rates were kept high to accord with those charged for boat tonnage. The barges could have been chartered at lower rates if the chartering had been done in an open market. Even those high in authority little understood the problem faced by tidewater coal users, but New England will have to make it understood if action is not soon taken.

It has been felt in trade circles that an adjustment of the railroad fuel problem would help clarify the status of coastwise shipping, because so large a proportion of railroad supply coal in New England has normally been shipped by water; but unless there is some coördination in the next few months between the two means of transportation, we shall experience difficulties far more serious than those we are now going through. Will not some capable man or body of men, in the Interstate Commerce Commission, or elsewhere, step forward and show some real grasp of this business of freighting coal?

Men, when they strike, do not strike so much against their employer as against the rest of mankind. Increased wages must inevitably come out of the pockets of consumers (all human beings are consumers) or out of profits. If they come out of profits, business is starved and becomes unprogressive and inefficient, and may even be destroyed as have been the railroads. Many of the street-car lines, owing to strikes, have been put out of business. A strike against mankind is justified only when the men striking are receiving a lower relative wage scale than their work and talent merit.

Why Doesn't the Consumer Get Busy?

CONSUMERS are the most futile of persons. They are always disposed to support any move for an increase in wages. When the increase is granted and costs rise in accordance, they are then extremely wrath that they have been bitten. They blame, however, the man that pays the larger wages and not the man who compels their payment. The consumer, like a child, puts his finger in the flame and wonders why it burns him and not somebody else.

There was a time when there were no labor unions or when labor unions were purely local things, and operators of coal mines could lower wage scales individually or locally and make a profit in so doing. In that period, long removed, so much removed as to be almost historic, it paid the operator to fight for low wages. At that time it became ingrained in the genus operator to resist the workman seeking an increase. It became a second nature, a nature so strong that the same spirit rules even though conditions have changed immensely, and the operator has now little or no reason for resistance.

Today unionism is not local. It is national, and the operator must everywhere pay the scale. The only questions are: Does the wage advance hit every producer equally? and "Can he pass it on to the public? Increases in mine wages do usually hit every producer in any industry almost equally. In steeply pitching measures where mining is unusually expensive, there is a difference in cost which is important, making wage increases naturally discriminatory and locally oppressive of the operator. But in general the operator is not moved by reason in opposing an increase, for surely the answer to the second question is that he can pass the increase in wage on to the public, wherever conditions are equal.

The average producer has now no cause for resistance. Let us hope he will never realize that conditions have changed so markedly that resistance to wage demands is merely patriotic and philanthropic and not a measure of self defense. Let us hope consideration does not drive that conclusion in on him, for he is moved so little, under normal conditions by patriotism and philanthropy that he will let his employees burden the public with high costs without any resistance whatever. Fortunately all the latent conservatism, and all the memories of bitter struggles when to win meant abounding profit and when loss meant impending gain makes a cave man out of the coal operator and he fights heroically for what he thinks is his own interest, but which is really the sole interest of the consumer. Meanwhile the consumer tries to trip him up. He brings pressure in every way to induce the operator to give up his battle.

Of course, there are wage battles in which the consuming public should take sympathetic interest, where, for instance, men are trying to get a percentage increase in proportion to their past wages equal to that already granted a large percentage of workmen. Labor unions will be excused if they look sympathetically on such struggles. But to aid all strikes, thinking it is helping the cause of labor, is a plain folly. The workman is a consumer. He is interested in seeking a lower wage for every other workman outside his family. Still, of course, as an honorable man, he will have no objection but rather a pleasure in seeing every good workman get a fair wage whether by striking or without such labor disturbance.

Some day the consumer is going to take a hand in preventing uncalled-for wage increases as unfair and unbalancing of labor conditions. We are all paying the wages of one another when we buy necessities and luxuries. We are all consumers. In so far as we are consumers, we are interested in keeping down the wages of production to a fair figure. We must not neglect that duty. We must not blame the employer if he does not perform it for us. It is the consumer's duty. Why, then, doesn't the consumer get busy?

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Labor matters are simmering gently. However, a little disposition seems to exist to ask the Government to take charge of the mines, but really the feeling is not strong. A Government that in some instances takes months to report casualties and pay soldiers' wages, to mention two matters only, is not likely to regulate business any better than it is now regulated.

The Government was the cause of the present overproduction of the coal. It is not at all to be blamed for it, of course. It is to its credit that it boosted production and made storage possible. But rightly or wrongly (it makes no difference which), it made this present condition and it would have made it had there been Government production rather than Government control.

If the people will not buy, even the Government will not produce coal indefinitely. If the coal is mined and stored in large quantities at one place it will catch fire and burn. After all, not all the idleness is at mines. The trouble is that the people will not buy. Will the Government compel the individual to buy against his will? The miner will say the public can be compelled to buy coal, but he will not readily admit that it can be required to buy a host of other things which could be made by people that are idle.

The public is like a child looking out at a rainy day. Almost the only course is to let it rain. An umbrella may be provided to shield us against some of the rain's violence, but on the whole what can we do to adequately meet the phenomenon? Why look to the Government? It has been slower than all other agencies since the war. It has shown less resilience than the average employer of labor.

The United Mine Workers of District No. 9 meeting at Kulpmont in the anthracite region feel that the Government should take the mines over. The men in Illinois have voiced the same idea. But it is not clear that it would lighten the burden at all and it is certain that leaving the affairs of the nation in the hands of one or a dozen men would not make for such efficiency as the present distribution of responsibility.

Board Gives Labor Favorable Decisions

After hearings covering several days Special Umpire Allison O. Smith, representing the United States Fuel Administration, rendered on Feb. 1 several decisions regarding matters long in controversy between the miners and operators of the New River and Winding Gulf fields. These points at issue were first presented to Judge Smith in December.

As to the increase in pay of monthly men he ruled that it should apply for every day worked, whether 25 or 31 days in the month. In the case of the employees of the Rayland Coal Co., who claimed that no allowance for yardage had been given them though it was stipulated in a contract with the company, Judge Smith gave his decision in favor of the employees. The discharge claim of D. L. Campbell against the Turkey Knob Coal and Coke Co. was settled by an agreement that the man should be reëmployed but that he should not be compensated for any time lost.

Further depositions were requested in a case growing out of a strike among the employees of the Elkhorn Piney Coal Mining Co., at Stannaford in Raleigh County. The employees of the company charge that the concern has not been living up to a decision previously given.

The statement made by the operators at the Feb. 1 meeting exhibits just how they regard the demand of the men for a new wage scale in the New River and Winding Gulf districts:

"Relative to your request for a conference at White Sulphur, W. Va., on or about Feb. 1, we desire to say that the New River and Winding Gulf Operators' Associations are of the opinion, and have so decided, that the United States Fuel Administration has heretofore, at what is known as the 'Washington Wage Conference' held at Washington, D. C., on Nov. 1, 1917, settled, for the period of the war, or until the peace treaty is signed, and possibly until April, 1920, the wage that should be paid our employees, thus rendering a conference between our employees and ourselves relative to wages unnecessary.

"The ruling of the fuel administration made at the 'Washington Wage Conference' is still in force and effect, and inasmuch as the ruling or order was accepted, adopted and acted upon by all the parties concerned, that is, the employees and employer alike, it became binding and by virtue of such adoption superseded the contract then in force between our employees and ourselves. In view of the status so fixed and determined by the Fuel Administration as hereinbefore mentioned, we have decided that we have no right to change the same during the time that such ruling, as heretofore announced, is effective."

With Peace Will Aliens Come or Go?

Although the operators in the Connellsville coke region have to learn what the Federal Congress or the Peace Congress may decide as to emigration or immigration, they are giving serious attention to the prospects of a general exodus of foreign-born mine and coke workers to Europe. The effect of an unlimited immigration program upon the labor situation in the region is also being studied.

Those, however, who have examined the matter most closely seem to be of the opinion that there will be no material exodus. They argue that should governmental restriction not prevent migration to Europe, the high taxation which will exist on that continent as a result of the war, possibly also the low wages and the unfavorable living conditions will discourage many of the foreign-born workers in the region from planning any extended stay in Europe, though some may make a short visit. Another factor is that the foreign-born worker, fearful of banks, has invested heavily in property in the Connellsville region and in federal securities which in many cases cannot be converted quickly into ready cash without a loss. The alien is usually a canny proposition in such money affairs.

It is believed that the more serious danger lies in an exodus of workers into the region. Of this there are prospects. Since the war began the aliens in America have learned more than ever the advantages of living in the United States and as their letters to relatives abroad have detailed their prosperity the war may easily result in a larger immigration than ever before.

Russians Not Coming to Western Canada

Considerable feeling has existed in some British Columbia and Alberta coal-mining centers relative to a report that operators were arranging to import Russian coal miners in order to permit of the fullest possible development of the mines. The rumor was denied, but it persisted, and as far back as Dec. 10 an inquiry was made by W. F. McNeill, Calgary, Alta., of the Department of Labor, at Ottawa, with the result that G. D. Robertson, Minister of Labor, sent the following explanatory letter flatly refuting the statement:

"In reply to your letter of Dec. 10 would say that, on Nov. 11, the department received notice to the effect that

the Canadian Pacific Railway Co. was negotiating with the Western Coal Operators' Association in regard to the importation of 400 Russian miners despite the fact that several of the Western mines through lack of orders were not then working to full capacity. My wire of Nov. 11 states that inquiry was immediately made in regard to the supply and demand for miners. That inquiry confirmed the statement that the mines were not fully occupied through lack of orders and that there was no necessity for importing miners from Russia.

"The Canadian Pacific Railway Co. was accordingly asked to discontinue any negotiations of this character. Subsequently the railway company advised that no negotiations had been in progress, which fact was later substantiated from other sources. Your letter indicates that an utterly incorrect interpretation was placed upon the telegrams exchanged."

Canadian Mine Worker Soldiers Resent Presence of Well-Paid Aliens

The Legislature of British Columbia has recently adopted a resolution advocating that all enemy aliens be deported from Canada and that the Canadian Government should be careful to retain full control of immigration to the Dominion, whatever other concessions may be granted at the Peace Conference.

The debate on this subject was of special interest to the coal miners and the workers of all industrial sections of British Columbia, but it was followed with particular keenness by the miners of Vancouver Island coal areas because the employment of aliens in the mines has for years been resented by the English-speaking classes of these sections. William Sloan, Minister of Mines, who is the representative of the latter districts in the House, spoke strongly in their behalf, supporting the proposal that the Dominion Government should be asked to deport all enemy aliens and moving an amendment to the effect that "Canada's representatives at the Peace Conference be asked to adhere firmly to the principle that Canada shall always exercise full control over immigration to the Dominion."

He not only wanted aliens put out of the country but wished to be sure that, once out, they would be kept out. This was a matter, he said, of primary interest to his constituents. The coal miners of the island, and in fact of the whole of the Province, had furnished considerable quotas to the Canadian Army. Their war record, as to fighting men provided and in every other respect was one of which they were proud. Now those who had gone were coming back to find, in many instances, that while they fought for their country at $1.10 a day, aliens had been filling their places at home at high rates of pay.

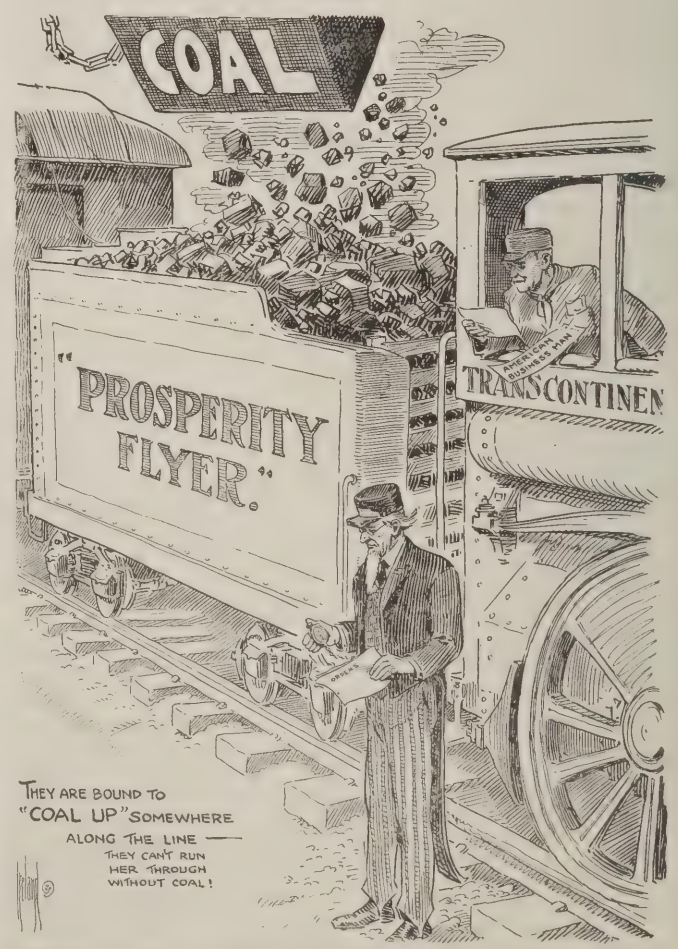
Their demand was that all enemy aliens should be returned whence they came, and their places filled by returned soldiers as far as possible and where this was not possible by British subjects. Recent statements indicated that the whole question of immigration was to be discussed at the Peace Conference. It was possible that, at such an international conference, some of the delegates developed a disposition to make concessions. He felt that Canada should not surrender in the slightest degree the principle that her Government control the character of the tide of immigration which was bound to flow from the mixed populations of Europe and Asia.

Canadians Will Make a New Wage Contract

The result of the election of officers of the United Mineworkers of America in District 18, which includes eastern British Columbia and the Province of Alberta, has recently been announced. In the contest for the presidency P. M. Christopher, of Blairmore, has defeated David Rees, of Vancouver, B. C., by a majority of 1486 votes. Alexander McFegan, of Brule, Alta., defeated William Dickenson, of Fernie, B. C., by 1100 votes for the vice-presidency. In the election of auditor G. Christie, of Bellevue, defeated William Potter, of Fernie, by 528 votes.

A second election had to be held before the offices indicated were filled, as the constitution requires that every officer must have over 50 per cent. of the votes cast and, in each case there were originally more than two candidates in the field. These officers will be installed Mar. 1, probably at the conclusion of the annual district convention. The newly-elected officers will be charged with the conduct of negotiations for the renewal of the working agreement with the Western Coal Operators' Association, which agreement expires on Mar. 31 next.

Want Political Prisoners Freed



The local unions of Carbondale and Coleman, Alta., Canada, which are affiliated with the United Mine Workers of America, have passed the following resolution:

"We indorse the action taken by the Alberta Federation of Labor Convention at Medicine Hat, demanding the release of all political prisoners incarcerated during the war and are ready to fall in line with any action the Executive of the Alberta Federation of Labor may take, no matter how drastic, to attain that end."

In particular much resentment is shown to the arrest and conviction of Thomas Shannon, secretary for the Diamond City local, near Lethbridge, Alberta, on the charge of having in his possession banned literature and other correspondence in connection with the local. The men argue that if the action taken against Shannon were to become general the secretaries of all unions would be placed in a precarious position and liable to arrest at any time.

The following resolution was carried:

"It is unanimously resolved that we urge upon all locals in the district to take immediate action in this matter, fix a date as early as possible, and all cease work until Brother Tom Shannon is released from prison."

BETTER DAYS ARE SURE TO FOLLOW. BE READY WHEN THEY COME

Turn About Is Fair Play

Miner—Give me some more, Columbia, me good lady, and a little for the other boarders, too?
Columbia—No more for you my friend. We can't keep any star boarders here. Already you have the share of the other boarders.

Every man is both worker and consumer. A worker in one industry is a consumer in another. When one group of workers gets increased wages, the other groups have to pay more for the goods produced by the first group. Mine workers' wages have risen more largely than the wages of bricklayers, stone masons, carpenters, teachers and others. These people have to pay the mine workers' wages, and they think they ought to make the mine workers pay them more before they are asked to pay the mine workers more. Remember the workers in many industries are getting but little more than before the war and they are entitled to first consideration.

DISCUSSION BY READERS

Coal, Railroads and the Government

Letter No. 1—The proposition presented by the Foreword, in *Coal Age*, Jan. 23, is an interesting one and, as stated, underlies, in a great measure, the future prosperity of the coal industry in this country. The question of the ultimate effect of government control of the railroads on the marketing coal is one that is beset with many possibilities. It is my opinion, however, that the action of the Government in taking over the railroads will prove a benefit to the coal industry.

Investigation by the Government into the conditions that hampered the production of coal revealed the influence exerted by the railroads, who controlled the distribution of the product of the mines in an unfair manner. Such was the condition that it became necessary for the Government to take a hand and assume the responsibility of railroad transportation and management. My belief is that, from the lessons then learned, the Government will not permit the coal industry to suffer a repetition of those influences that held it in restraint at that time.

The crisis brought about by the war furnished the chief reason for the Government assuming the control of the railroads, in order to bring about a more equitable distribution of car supply at the mines, establish a suitable zoning system for the marketing of the coal produced, and in other ways relieve the serious fuel situation that then existed.

Railroad Influence Restricts Coal Industry

Judging from the information available, it would appear that the railroad companies have never done anything to improve the coal business. Their action in buying large quantities of coal at the mines, at their own price, has been most unfair, especially to the smaller operators. The effect has been to injure the business.

It was, previously, in the power of the railroads to control the supply of cars to the mines to their own advantage. The resulting car shortages prevented many operators from meeting their coal contracts. It is my hope and belief that government ownership will eliminate these conditions and establish a more equitable basis for the marketing of coal than has hitherto existed.

Even when the Government fixed a maximum price, per ton of coal at the mines, the railroad companies claimed that a special price should be made to them, owing to the large consumption of coal in the operation of their engines. This and other questions of similar import must be settled by the Government, in their administration of railroad matters.

While there are many Government reforms necessary to be made, before one can say positively that Government ownership of railroads will be successful, there is scarcely a doubt but that such ownership will prove a benefit to a large number of coal operators.

It will be well for operators to consider carefully how this action of the Government is going to affect their business, and prepare to meet the problems that will be presented under the changed conditions, with a view to counteracting any injustice that might otherwise inadvertently fall to their lot. W. H. Luxton.

Linton, Ind.

Effect of Prohibition in Mining

Letter No. 2—From numerous letters that have appeared recently, in *Coal Age*, discussing the many hindrances to coal production, it seems to be the general opinion that the use of intoxicating drinks was the greatest hindrance. Most of these letters came from writers in wet states; but, even in this dry state of West Virginia, the intemperance of miners is a distressing problem to the coal industry.

Time was when every thatched roof sheltered at least one jug, even at the expense of the loaf of bread; and the song commonly sung was,

> "Father, Oh Father, come home with me now,
> The clock in the steeple strikes one."

A Sunday, then, seldom passed without its cutting or shooting scrape; a wife driven from her home and a general assortment of broken bones, cut faces, bleeding noses, torn clothing, shattered dishes, and domestic broils too numerous to mention.

Mondays were days to be dreaded by the coal operators. Few men showed up at the mine and those that did might just as well have stayed at home, so far as their ability to work was concerned. It was no uncommon thing for a mine superintendent to go to the house of every man who failed to appear at the mine and drag him from under a bed or from a closet in which he was hiding and compel him to go to work.

Effect of State Prohibition

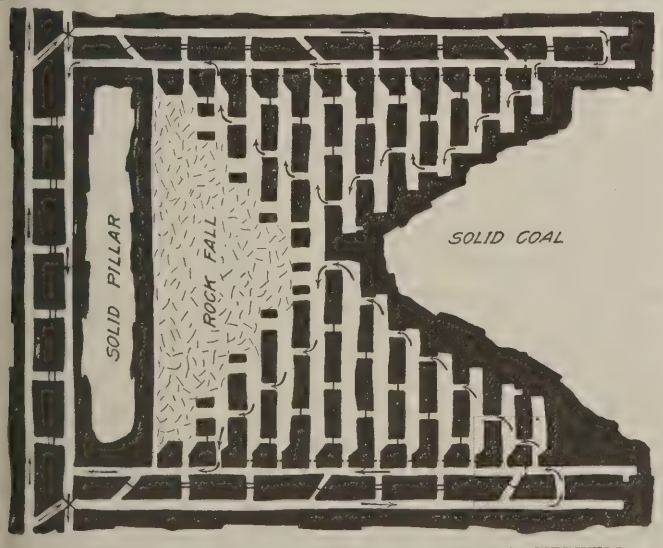
Such, more or less, were the conditions in West Virginia mining camps when the state went dry. Then, for a time, there was a marked improvement; but, unfortunately, this section is as a small desert surrounded by three wet oases, as it were. Following each payday, a large proportion of the mining population of the district visits some near-by town in Ohio, Pennsylvania, or Maryland, in the fond hope of bringing with them on their return what the state law has prohibited here. At times, they "get by"; but more often the assumed innocent expression and nonchalent air, ludicrous to the onlooker who knows their habits and ways, betrays them to the authorities, and they are locked up and their recent purchases confiscated.

Another feature of state prohibition is the resulting home manufacture of what the foreign element fondly call "light wine." From its effects, the appellation given to this beverage seems to refer more to the head of the drinker than to the drink. The man becomes fairly crazed and his utterances are as ridiculous as

the fantastic performances he executes when under the influence of this drink. In one instance, the drinker tore up his parlor carpet; and, then, not satisfied with that took from its hiding his savings of several months and staked them at a game, which he lost in less time than it takes to tell it.

This "light wine" is made every fall by the French, Italian, Austrian and Hungarian elements. They do this with the same regularity that the housewife performs her summer canning of fruits and vegetables. They manufacture several hundred quarts for home consumption alone, and often more for outsiders. In one house in the Morgantown district, the authorities found and seized several thousand gallons of this wine. The drinker will seldom tell the name of the one who sold him the drink or say where he procured the beverage.

Today, this country is waiting with impatience to see the effect of nation-wide prohibition on mining conditions. The fear is often expressed that something bad or worse will be found to take the place of that which is lost. The coal industry must wait and hope for the best. M. P. H.



Rosemont, W. Va.

Drawing Pillars in Machine Mining

Letter No. 5—It pleased me much to see the method that I described for drawing pillars in machine mining appear in *Coal Age*, Feb. 6, p. 288. However, I am afraid that I did not make myself clear in regard to the method of attacking the pillars, since the figure given on page 288 shows that they are being cut on the side toward the falls.

That is wrong, as when a fall occurs from the drawing of the last pillar it will generally extend clear across the room and make it impossible to draw the next pillar from that side. The cut must therefore be started on the opposite side of the pillar from the falls.

In order to make my point more clear and to explain more fully how this method can be applied equally

DRAWING PILLARS IN THE ADVANCING SYSTEM

well when rooms are turned off two pairs of headings and driven to meet each other, I have prepared the accompanying sketch showing such an arrangement. It will be observed that the circulation here shown is suited to a gaseous mine, the intake air being conducted to the face of the crossheadings, where it enters the last room turned and passes back over the working faces of all the rooms before reaching the gob section where pillars are being drawn.

This plan not only provides for the ventilation of the working faces with fresh air and carries the gases generated in the pillar workings directly into the return airway; but, by advancing the crossover so as to keep pace with the pillar workings, all the coal from the rooms can be hauled out on the intake air. If desired, the coal from the pillar workings can be back-switched when the crossover to the intake is carried further forward. As fast as the ribs in the rooms are drawn, the section of road on the return airway is abandoned and the track lifted.

Pillars Attacked on Side Opposite to Falls

The plan shown in the figure is the advancing system of mining, which gives an early development of the coal. It will be observed that all the pillars are attacked, in the manner previously described, on the side opposite to the falls, which is the particular feature to which I desired here to draw attention. In the figure are shown thirteen places turned; one rib has been drawn back and is finished, while four other ribs are being drawn. Work on the sixth rib will soon be started at the face of room No. 7, which is just finished. The remaining six rooms are still working on each pair of entries.

When the entries have been been driven up and the rooms and ribs all drawn between the two pairs of headings that are shown in the figure, the work of retreating is started by turning rooms on the other side of these entries and working them back on the retreating system, after the same manner as has just been described in respect to the advancing system.

As the work progresses and the pillars between the rooms are drawn back, the entry stumps and chain pillars are taken out by the same system of retreating. Less and less difficulty will be found with the breaking of the roof, as the face over which the roof pressure is exerted is increased by the extraction of the coal, becoming practically double what it was previously. This will insure good roof falls and lessen the danger of a creep developing. D. F. M.

Meadow Lands, Penn.

Letter No. 6—I was much interested in reading the practical question of "Operator," *Coal Age*, Jan. 2, p. 32, asking for information in regard to the best method of drawing pillars in machine mining. Kindly permit me to give a little of my own experience.

In the coal mines of Australia, where I was formerly employed, conditions are more adapted to the use of machines than is generally the case in the mines of British Columbia where I am now working. However, I believe there are many localities here where machine mining could be employed to advantage, particularly as this system does not require a practical knowledge of mining coal, on the part of the man running the machine. He must, however, be able to operate a machine properly and keep things running regularly and systematically.

In machine mining, where pillars are to be drawn, the safest plan to adopt, in my opinion, is the following:

In British Columbia, the law requires that both the machine runner, who must be a practical man, and his helper must have a miner's certificate of competency. These two men will be able to handle, say four places and make a 5-yd. cut in each place, in a single shift of 8 hours.

Now, assuming the working places are double, the machine runner and his helper first make a cut, say in No. 1 left. When this is finished, the runner transfers his machine to No. 1 right, where he makes another cut. When that is finished, he takes his machine around to No. 2 bord or chamber and repeats the operation there, first making a cut in No. 2 left and then transferring his machine and making another cut in No. 2 right.

In the meantime, two loaders have started to load the coal that has been drilled and blasted by the miners working in these places. The work of loading is started in No. 1 left, the loaders following the machine and loading out the coal as quickly as it is blasted. There are also two practical timbermen, who do what timbering is necessary for the proper support of the roof, for the protection of the machinemen and loaders, so that each place will be ready for the machine to make another cut on its return.

A thin strip of coal is always left on the gob side when cutting through the rib. This is necessary to protect the machine and the men until that lift is finished. When a lift is finished, two practical miners are employed, at the current tonnage rate, to dig out the strip of coal left by the machine.

Success in Pillar Work Depends on Numerous Items and Considerations

In some instances, these miners drill and blast the coal after it is cut with the machine. At other times, the machinemen are provided with a rotary drill operated either by compressed air or electricity. In that case, it takes but a short time for the machine runner to set up the drill and put in three holes, one in the center and one on each side of the cut. This procedure, however, is at the option of the mine manager (foreman).

Any kind of labor will answer for the loaders, who will be under the direct charge and care of the timbermen. The success of the operation, the amount of coal recovered in drawing back the pillars, and the amount of timber saved will depend on the quickness with which each lift is cut through. Strong cogs should be built at the mouth of each lift to give better protection while the work is being performed. The front and bottom of the cog is set on a little mound of dirt to facilitate the withdrawal of the timbers forming the cog.

It is important to withdraw all timbers and other supports as the work proceeds, particularly where the coal is overlaid with a strong sandstone roof that is difficult to break. When timbers are left in the gob, the weight will be thrown forward on the pillars, which will induce a creep or squeeze, and it is necessary to guard against this contingency.

If desired, the above procedure can be varied by the practical miners doing their own loading and timbering, besides drilling and blasting the coal and mining out, with picks, the thin rib of coal left behind the machine. This will result, in most cases, in a considerable reduction in the current tonnage rates.

Wherever conditions are favorable to the use of machines, they should be employed as a means of increasing the production and lowering the cost. The system that I have described can be carried on in any number of districts desired, at the same time. However, the safer way would be to start with one district and learn what is necessary to effect any desired improvement in the method. This will, also, overcome the natural prejudice of the average miner, by beginning in a small way. The miner is generally inclined to oppose new methods; but most miners now prefer loading after a machine, to the old system of pick mining.

Matthew Stafford.
Chase P. O., Vancouver Island, B. C.

Safety in Shotfiring

Letter No. 1—Only recently, my thoughts have been recalled to an inquiry of a correspondent in Colorado, published a year or more ago. [*Coal Age*, Vol. 12, p. 647]. The inquirer desired to know to what extent the work of shotfiring was safeguarded in mines generating gas, and to what extent the mining laws of different coal-producing states discriminated between the firing of shots in gaseous and nongaseous mines.

As I say, my thoughts have been recalled to this inquiry by an accident that occurred a short time ago to a shotfirer, who was severely burned by igniting a quantity of gas with his carbide light. In this instance, the mine was classified as a "gaseous mine" and the law required the use of electric lamps, besides imposing other restrictions in regard to the powder used in blasting, copper-tipped tamping bars, etc.

The shotfirer, in this case, had 90 shots to fire and was accustomed to do his work in 4 hours. In his haste to finish, he neglected to make the required examination for gas before preparing the shots and further violated the law by using an open light. No objection had been made to this rapid work. As usual, we go on believing that everything is all right and ignore the fact that the law is being violated, until someone is hurt or killed, and then an effort is made to fix the blame.

Improved Methods Needed in Shotfiring

We have done well in saving thousands of lives by adopting improved shotfiring systems and making this a requirement of the law. Now, let us get busy and try to save the shotfirer from his own heedless neglect of these requirements. We may find that the coal-mining laws of Colorado will have to be altered so as to place more responsibility, for the proper performance of this work, on mine officials, who should know that the shotfirers whom they employ are fulfilling all the requirements of the law.

When a shotfirer is employed, he should be given to understand that 8 hours constitutes a working shift. His time should be divided so that 2 hours should be employed in making the examination of the working places, in his section of the mine. Then, 3 hours should be required to prepare, tamp and fire the shots, followed by an hour's rest and then 2 hours for making an examination of all places in that section, for fire and other dangers.

While the coal-mining laws of Colorado are good laws and insure ample safety when they are not violated,

trouble frequently grows out of the classification of mines by the state inspector, as required by law, designating certain mines as "gaseous" and others "nongaseous." It is my belief that every mine in Colorado should be classed as a gaseous mine and only electric lamps be permitted to be used except in testing for gas when it is necessary to employ an approved type of safety lamp, in the hands of a competent fireboss.

But, aside from the trouble growing out of difference in classification, there are many violations of the law, such as the use of open-flame lamps and matches by firebosses; the use of fuse, which is too often ignited by a match, a lamp flame, cotton cord or punk.

Igniting the Fuse in Presence of Gas

In many instances, firebosses have been instructed to use cotton cord or punk. One instance is recorded where a shotfirer had his eyebrows, nose and the back of his neck burned with gas that was inflamed when he used cotton cord to ignite the fuse, in firing a shot. He had been told that cotton cord and the spit from a fuse would not ignite gas; but, at the same time, he no doubt knew that he was violating Sec. 154 of the mining law.

In many instances, shotfirers are not intelligently informed in regard to what methods must be employed in the performance of their work, in the presence of gas. The object and aim of mining laws and the desire of the people is to secure safety in mines. It is my belief that the conditions that relate to safety, particularly in regard to the use of black powder, methods of firing and the time that should be employed in performing this work, as well as the ascertaining of the competency of firebosses who are employed, are not sufficiently outlined in the state mining laws.

The lesson is brought home to us, from time to time, that either the shotfirer's duties must be performed in the strictest compliance with the laws as they stand, or new laws must be made to safeguard the work of shotfiring in our mines. Robert A. Marshall.

Farr, Colo.

Efficiency in Firebossing

Letter No. 5—Having given much time and study to efficiency, in the work of firebossing in which I have been engaged during the past few years, I was greatly interested in the letter signed F. G. J., *Coal Age*, Dec. 19, p. 1133. I fully agree with the writer of that letter in his statement that "firebossing, in many coal-mining states, offers little inducement to the best-trained men." There is little incentive for men to study and prepare for this position, as it is at present regarded in many mining districts.

When a position begins to lose its importance and value, in the minds of the higher officials of an industry, it is bound to be classed or regarded by highly trained men as a position not worth having. In one instance that came under my observation recently, I noticed that it was a difficult matter to keep firebosses on the job. Inquiry as to the cause developed the fact that, after the morning examination of the mine, the firebosses employed there were compelled to go to work as ordinary daymen. However, the plan did not work well and the foreman, who thought that he could run the whole mine himself after 7 o'clock, openly admitted, a few weeks later, that "the man who does not consider the duties of his firebosses as important if not greater than his own is not working for efficiency in general."

A foreman who is wise enough to give credit to a good fireboss is unwittingly encouraging him to work in his own (the foreman's) interest, as well as that of the company and himself. A good fireboss means more to a mine foreman than anything else. At times, a danger arises in all mines that requires the best judgment and experience of a competent fireboss, to insure safety. A foreman may then rest contented while his fireboss directs the work. At the same time the foreman is free to attend to other matters that may need his personal oversight. Contrast this condition with a foreman who cannot trust his firebosses or who has failed to gain their confidence. Necessarily, such an one must give his attention to the matters that should be in charge of a man trained for that particular work.

Responsibility and Authority of the Fireboss

My opinion is that a competent fireboss should be counted the most important official on the daily force of a mine. He is responsible for the safety of both the men and the mine, and on his actions largely depends the production of coal in that mine. When a fireboss is underestimated by the other mine officials, the men are prone to disregard his orders, knowing that he is not backed by the foreman; whereas, an order of the fireboss should be *the last word* in respect to the safety of a mine, if accidents are to be avoided and the mine made healthy and safe for work.

A competent fireboss is as important to a mine foreman as the superintendent is to the company, because he spends all of his time in the mine and knows well the condition of every place in his district. He is always able to give any needed information that the foreman may ask.

In case of disaster or danger from fire, explosion, or squeeze in the mine, a competent fireboss has generally prearranged plans of what is necessary to be done for the safety of the men and gaining control of the situation. In his efforts to forestall any danger that may arise in the mine, the fireboss should never be discouraged by the other mine officials, which he is when his work, in that direction, is discounted by them as not of immediate importance.

Observing Firebosses Assist Their Foremen

The advantage that a foreman takes of the knowledge to be gained through his firebosses, is plainly evident by the inquiries he makes, each morning, in regard to how much coal is standing in certain parts of the mine ready to be hauled to the bottom, and what coal is loaded at the working face, besides asking for other information regarding trackwork and timbering that will assist the foreman in starting the men on the most important work to be done that day.

It goes without saying that the first consideration of a fireboss is the safety of the men in his charge, and when he is burdened with looking after matters pertaining to the movement of coal and the work to be performed by daymen at the start of the day's run, his own duties will naturally suffer. In his hurry,

many small matters that menace the safety of the mine will often escape his notice or be set aside for attention later. There is no question but that the efficiency of a fireboss is greatly lessened when he is compelled to attend to matters that should be looked after by others.

At the mine where I am at present employed, I am proud to say that the firebosses are given ample time to do their work properly. There is a good system in use regarding the movement of the coal. When the fireboss checks the men in the morning he marks on a blank, furnished for that purpose, what coal each man thinks he can load that day.

The runner in each lift gets this blank, which he returns to the foreman at the end of the shift, and reports how many cars each man has loaded and whether or not a loaded or empty car is standing in each place, besides the number of loads and empties on the main branch of each lift. This arrangement relieves the fireboss of all matters, except those pertaining to the safety of the mine, and has resulted in a remarkably low accident list, which is entirely due to the efficiency of the work of firebossing in this mine.

Low Standard of Efficiency in Firebossing

Were it not for the discouragement of the situation, it would be amusing to enter a fireboss station, in the morning, and watch him give his orders to the daymen and then proceed to daywork himself. Where a foreman has occasion to censure a man for not doing a fair day's work, the man comes back with the excuse that he has done as much as the fireboss, who gets more pay for the same work. The man apparently forgets that the fireboss has already done half a day's work, in making his morning examination of the mine.

Such a system presents a low standard of efficiency and sows the seeds of discontent among the men, which causes no end of troubles to the foreman. Where competent firebosses are subject to such treatment, it will be difficult to hold them in that position. The really competent fireboss will seek work elsewhere, before he will tolerate a low estimate of his ability and the importance of the work he performs.

Then, in closing, let me say that the only way to secure true efficiency in firebossing is for the higher officials of the mine to recognize the importance of that position and permit firebosses to give their whole time and attention to matters pertaining to safety.

Plymouth, Penn. Joseph R. Thomas.

Letter No. 6—I read with much interest the excellent letter of F. G. J. on this subject, *Coal Age*, Dec, 19, p. 1133. That writer emphasizes the point that "the fireboss should be, and is, in many mines and in many respects, as important as the foreman." There is little doubt but that being so considered will establish confidence in the fireboss, stimulate his ambition and increase the efficiency of his work.

The same writer, in closing his letter, urges that the fireboss "be regarded as a mine official, put on the salary list and treated by the mine foreman as his assistant." I wonder how many of the firebosses, in Colorado, desire to be put on the salary list, as formerly, when they were paid $110 a month for their services. The present wage scale of the fireboss, here, is $5.95 per day, which enables him to make from $178 to $184 a month. The salary of the mine foreman was formerly $130 per month and, by the present wage scale, that official draws $185 per month.

The fireboss in Colorado is a mine official in the meaning of the mine law, which provides for his examination and certification in common with other mine officials and, in my opinion, the fireboss is such an official. For the sake of argument, allow me to disagree with the suggestion made in the letter to which I have just referred that the fireboss should be "treated by the mine foreman as his assistant."

The Colorado coal-mining law provides for the employment of assistant mine foremen, whose duties are to carry out the instructions of the foreman and take his place in his absence; but the duties of the fireboss are of a different nature. That official goes home at 11 a.m., not to return to the mine until about 4 p.m. It is easy to see that he occupies a distinct position in the mine, and his efficiency depends only on the manner in which he performs his duties.

If the fireboss was an assistant to the mine foreman, he would have to obey his instructions. Right here is where trouble would begin. Suppose, for instance, that a fireboss is busy putting up a brattice to remove the bad air from a working place and the foreman orders him to make the second examination of the mine. The fireboss drops his work on the brattice to obey the instructions of the foreman, with the result that the miners who are thus left working in bad air get sick and go home.

However, the fireboss would seldom complain when thus called away, because he is given an opportunity of visiting the working places and marking the date on the face of the coal in any place where, in his hurry in the morning, he has failed to do that which the law requires. The foreman sees the date on the face, later, and believes the fireboss is efficient.

Need of Revising Mining Laws

It is a pleasure to know that the columns of *Coal Age* are open to any suggestions that are intended to make the mine more safe; and I want to say that it is my belief that the Colorado law could be revised to advantage, in one or two instances. In my estimation, the law should provide that the fireboss should enter the mine at 1 a.m., having with him a bratticeman and timberman. With their assistance, it would be possible to erect the necessary brattices for the removal of gas; or set such timbers as may be required to support bad roof; or take down a loose piece of top that is about ready to fall. By removing these dangers promptly when found, the efficiency of firebossing would be greatly improved.

Again, greater safety would be insured if the law provided for the appointment of a safety inspector instead of the present assistant foreman. A first-class, certified, mine-safety inspector or examiner would find ample opportunity for his services, in every gaseous mine and wherever dangerous roof conditions exist. Copies of his report made at the close of each shift and stating what dangers were found should go to the manager of the mine and the state mine inspector, which would inform them of the general safety of the mine.

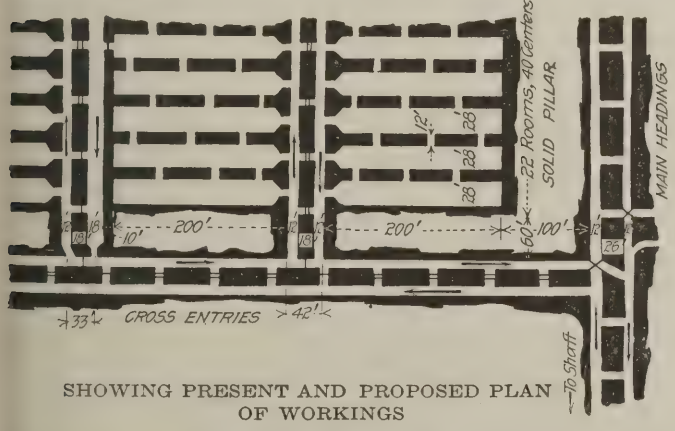
Farr, Colo. Robert A. Marshall.

INQUIRIES OF GENERAL INTEREST

Belting Used in Anthracite Breakers

Can *Coal Age* or any of its readers inform me in regard to the amount of leather and rubber belting used in the operation of a modern anthracite breaker? I am desirous of securing figures that will show, approximately, the amount of belting required to operate an uptodate anthracite breaker, capable of handling a given tonnage per day.

In other words, I want, if possible, to compile an estimate showing the amount of belting required, either leather or rubber or both, per ton of coal handled. I do not refer to the amount of belting consumed in a year or other period of time; but, simply, what amount of belting is required to equip a modern breaker.



Scranton, Penn. MECHANICAL ENGINEER.

This question should not be difficult to answer, where one has access to the working plans or drawings of a modern breaker, such as is in use today throughout the anthracite region. We hope that some of our readers who are able to give this information will reply to this inquiry, as the information thus offered would be a valuable contribution to technical mining literature.

Panel System of Mining

The mine of which I have charge is a machine mine, all the coal being undercut with a 6-ft., Sullivan, shortwall machine. As indicated in the accompanying figure, the mine is worked on the panel system.

Cross-entries or panel-entries are driven off the main headings, about 1000 ft. center to center. Room or butt

SHOWING PRESENT AND PROPOSED PLAN OF WORKINGS

headings are then turned on one side only of each pair of panel headings. The room headings are driven on 442-ft. centers, which allows for rooms 200 ft. deep, turned to the right and left of these headings.

The width of all entries is 12 ft. and the entry pillars are 18 ft. wide. A solid pillar of coal 100 ft. wide separates the main headings from the faces of the rooms. The rooms turned to the right and left of the butt headings are driven on 40-ft. centers and widened to 25 or 30 ft., which makes the room pillars vary from 10 to 15 ft. in width.

There are several disadvantages in the employment of this system. In the first place, there is always a back haul for all coal mined in the rooms driven toward the main heading. This back haul amounts to about 200 ft. when these rooms are about finished.

Again, it frequently happens that much coal is lost, owing to bad roof conditions, poor ventilation, and the difficulty of maintaining good roads in the rooms where the drainage is often poor. Owing to these causes, the cost of getting out the last of the coal, between two pairs of butt headings, is more than the coal is worth and necessitates its being abandoned and lost beyond recovery.

Another bad feature is that the panel entries, in this system, must be driven forward a distance of 442 ft., before another pair of butt headings can be turned, which is a long way to go for a single car of coal. But, more important still, is the slow development of the mine necessitated by this plan. Because of these hindrances, we have been seriously considering changes that will overcome the most or all of the objections mentioned. The proposed changes are as follows:

As shown on the left of the figure, when the panel headings have advanced a sufficient distance, an 18-ft. air-course and a 12-ft. roadway, separated by an 18-ft. pillar, will be turned at such a distance as to leave a 10-ft. solid pillar between the air-course and the faces of the 200-ft. rooms driven from the last pair of butts. In this plan, there will be no back haul; and it will be possible, by holing through from the air-course, to reach and recover any coal that may have been left in the faces of the old rooms.

This proposed system can be continued indefinitely by driving a similar 18-ft. air-course and 12-ft. roadway across the faces of the 200-ft. rooms, as before, and leaving a 10-ft. solid pillar to protect the air-course. The panel entries will then require to advance only 258 ft., before turning a new pair of butts. Kindly say if, in the opinion of *Coal Age*, this proposed plan will improve the present system. R. J. PICKETT.

Shelburn, Ind.

There is no question but that the proposed change will prove a great advantage over the system formerly employed. We shall be glad, however, to hear the opinions of *Coal Age* readers on this proposition.

It is possible for practical miners to offer many good suggestions and criticisms on the proposition presented in this inquiry and, by so doing, give this correspondent the benefit of their experience. Many letters, received from time to time, bear testimony to the helpfulness of this department of *Coal Age*, when their inquiries have been taken up and discussed by readers.

EXAMINATION QUESTIONS

Mine Managers' Examination, Springfield, Ill., Dec. 17, 1918

(Selected Questions)

Ques.—To increase the velocity from 5 ft. per sec. to 10 ft. per sec., how much will it be necessary to increase the ventilating power and what will be the increase in the consumption of coal to accomplish this purpose?

Ans.—Other conditions remaining unchanged, the power producing circulation in an airway varies with the cube of the velocity of the current. In this case, the velocity being doubled, the power must be increased eight times.

For the same quality of coal and efficiency of the plant, the coal consumption is proportional to the power generated. To double the velocity, then, will require eight times the weight of coal consumed.

Ques.—What power will be required to give a current of 60,000 cu.ft. of air per min., in a mine having four equal splits, the airway in each split being 6 x 8 ft. and 5000 ft. long?

Ans.—In this case, the total sectional area of the four splits is $4(6 \times 8) = 192$ sq.ft. and the total rubbing surface $4 \times 5000 \times 2(6 + 8) = 560{,}000$ sq.ft. The velocity of the air in each split is $60{,}000 \div 192 = 312.5$ ft. per min. The power on the air, in this case, is therefore,

$$H = \frac{ksv^3}{33{,}000} = \frac{0.00000002 \times 560{,}000 \times 312.5^3}{33{,}000} = 10.35\ hp.$$

Ques.—If a collar or crossbeam, 10 in. in diameter and 6 ft. between notches, bears a certain load, what should be the diameter of a collar 12 ft. between notches, to bear the same load?

Ans.—As the question reads, it refers to the total load borne by the collar, in each case. Then, assuming an equal load is uniformly distributed over the length of each collar, the diameter of the collar will vary as the cube root of its length. In other words, in that case, the diameter ratio is equal to the cube root of the length ratio. Calling the required diameter of the 12-ft. collar x, we have,

$$\frac{x}{10} = \sqrt[3]{\frac{12}{6}} = \sqrt[3]{2} = 1.26$$

$$x = 10 \times 1.26 = 12.6 \text{ in.}$$

It is evident, however, that this does not represent the condition of a load on a collar, in mining practice where a 12-ft. collar, being twice as long, must carry twice the load of a 6-ft. collar. Hence, in mining practice, it is the unit load, or load per foot of length of collar, that is the same in each case, and the diameter of the collar then varies as the cube root of the square of its length; or,

$$\frac{x}{10} = \sqrt[3]{\left(\frac{12}{6}\right)^2} = \sqrt[3]{2^2} = \sqrt[3]{4} = 1.587$$

$$x = 10 \times 1.587 = 15\tfrac{7}{8}, \text{ say } 16 \text{ in.}$$

Hence, a 12-ft. collar, capable of withstanding the same roof pressure as a 6-ft. collar 10 in. in diameter, must have a diameter of practically 16 inches.

Ques.—An entry is parallel to a landline and 150 ft. from it. If the rooms turned off the entry run at an angle of 45 deg. with the entry, what distance can they be driven, allowing a barrier of ten feet to comply with the mining law?

Ans.—Since the sine of 45 deg. is 0.707, the length of the room measured on the straight rib, from the entry to the boundary line, is $150 \div 0.707 = 212.1$ ft. The same result is found, in this case, by extracting the square root of twice the square of the distance between the entry and the landline; thus,

$$\sqrt{2 \times 150^2} = \sqrt{45{,}000} = 212.1 \text{ ft.}$$

Ques.—With three horsepower, we are producing 20,000 cu.ft. of air per minute; how many horsepower will be required to produce 40,000 cu.ft. of air per minute, in the same airway?

Ans.—For the same conditions in the airway, the power producing an air current varies directly as the cube of the quantity of air in circulation; or, in other words, the power ratio is equal to the cube of the quantity ratio. Then, calling the required power, in this case, x, we have

$$\frac{x}{3} = \left(\frac{40{,}000}{20{,}000}\right)^3 = 2^3 = 8; \quad \text{and } x = 3 \times 8 = 24 \text{ hp.}$$

Ques.—(a) Does a high water gage always indicate a large quantity of air passing? (b) What does a low water gage with a large quantity of air passing indicate?

Ans.—(a) No. A high water gage may be caused by an undue length of airway; a restricted sectional area of the airway; or an obstruction in the air-course, all of which will increase the resistance of the mine and decrease the quantity of air in circulation, for the same power applied.

(b) The circulation of a large quantity of air under a low water gage indicates an ample sectional area of the air-courses, and shows that they are free from obstructions that would hinder the flow of air through them. In a large mine, the conditions mentioned indicate that the air current is divided into two or more splits, which reduces the velocity of the air and the mine resistance.

Ques.—What are the breaking strain and safe working load for a good steel rope $1\frac{1}{8}$ in. in diameter?

Ans.—For a 6-strand, 19-wire, crucible cast-steel, hoisting rope $1\frac{1}{8}$ in. in diameter, the breaking strain is $S = 39\ (1\frac{1}{8})^2 = 49.36$, say 50 tons. Using a factor of safety of 5, the safe working load on this rope is 10 tons.

For a 6-strand, 7-wire, crucible cast-steel, haulage rope, $1\frac{1}{8}$ in. in diameter. the breaking strain is $S = 37\ (1\frac{1}{8})^2 = 46.83$ tons; and, using the same coefficient of safety, the safe working load of this rope is $46.83 \div 5 = 9.36$ tons.

FOREIGN MARKETS AND EXPORT NEWS

Coal Imports of Greece

Greece in normal times imports more than 500,000 tons of coal annually. This amount consists usually of 10 per cent. Welsh coal (best Cardiff); 25 per cent. second quality Welsh (Newport), containing 20 to 30 per cent. of small coal used for factories and steamers; 10 per cent. of second quality used only for obtaining gas; 35 per cent. bunkering coal (Durham, Yorkshire and Northumberland); 10 per cent. patent briquets; and 10 per cent. German coal. As will be seen from this, England has had practically the monopoly of coal in the past. After the outbreak of the war America shipped a certain quantity of coal to Greece. American coal that sold best was the Pocahontas grade.

The question whether America can compete with England depends in great measure on return cargoes. In the past English vessels usually unloaded coal at Piraeus on their way to a port in the Black Sea to load grain. They thus brought coal to Greece at a nominal freight, preferring to do this than go out in ballast. Therefore, if the United States is to compete with England in this commerce, it will have to be assured that ships exporting coal to Greece will come back laden. It is thought that this might be done through arranging cargoes of tobacco, skins, emery, magnesite and marbles from Greece, with licorice root, carpets, dried fruits, emery and tobacco from Turkey.

In normal times ships discharged in the port of Piraeus at the rate of 400 tons per day, except when a strong southeast wind was blowing, which made unloading difficult. After the outbreak of the European war, when even a few days' delay meant a great loss to a steamer, owing to the increase of freights, steamers of four or five thousand tons succeeded in unloading 500 tons a day on an average. It has been stated, however, that larger ships with four holds and separate winches for each hold could discharge easily 700 tons per day.

Formerly the coal merchants at Piraeus held a stock of about 60,000 tons of coal available for purchase at $5 to $9 per ton. After the war broke out and up to the time of the blockade of December, 1916, to June, 1917, fair amounts of Welsh steam coal and American Pocahontas could be obtained at Piraeus at $55 or $60 per ton.

Ships coming in during that period and desiring coal, on giving notice the evening before, could begin coaling the next morning at the rate of 300 tons per day; in those days coal was always kept on lighters. A fleet desiring to coal could, on four or five days' notice, obtain 1000 tons daily.

A list of the principal coal merchants of Piraeus may be obtained from the Bureau of Foreign and Domestic Commerce or its district and coöperative offices upon referring to file No. 104,449.

Shanghai Coal Market

Under date of Jan. 16, Wheelock & Co., of Shanghai, report that the annual contracts for Japanese coal for 1919 have been concluded, and that buyers can consider themselves fortunate to have closed their contracts when they did, as prices have risen still higher in Japan owing to large orders for the Government railways and increased industrial and shipping requirements. It is hoped that during the year the output of the Japanese mines may be somewhat improved, but there seems to be no doubt that the demand for coal will far exceed any possible increase in output that may be attained; so that there is little prospect, judging from present indications, of any easing up in prices.

Owing to various difficulties caused by insufficient labor and transport facilities the Fushun coal mines have found it quite impossible to cope with the demand and they have been forced to ask for some delay in deliveries. These mines will not be able to entertain any new business for some time to come.

A large demand continues for the better grades of Kaiping coal, and although the freight market is slightly easier than it has been, it is not expected that there will be any large slump in local freights, as the building of small vessels has been neglected for the past two years. Some idea of the extension of the Kaiping coal market can be gathered from the fact that during the last few months over 40 steamers per month have left Chinwangtao for Dalny, Korea and Japan—a business that did not exist a few years ago.

Increase in Coal Exports

Some indication of the growth of coal exports from Norfolk, Va., within the past twenty-five years is shown by a comparison between the figures for January, 1894, and January, 1919. During January, 1894, William Lamb & Co., agents, exported 120,051 tons of coal from the port of Norfolk. This, export authorities say, represented practically the entire shipment of coal from the port during that month.

The records for January, 1919, show that during that month the coal shipments from Norfolk aggregated 796,139 tons. This includes the dumpings of both the Norfolk & Western piers at Lambert's Point and the Virginian piers at Sewall's Point. The total coal exports for all of Hampton Roads, which includes, besides the Norfolk & Western and the Virginian, the Chesapeake & Ohio piers at Newport News, were 1,068,262 tons.

Hampton Roads exports, as divided between the three big coaling terminals, for the month is as follows: Norfolk & Western, 490,336; Virginian, 305,803; Chesapeake & Ohio, 272,123.

The records show an increase of 209,894 tons for January, 1919, over the same month of last year, the exports for January, 1918, being 858,368 tons. Exporters say that this is due in a measure to the railroad tieups during the unusually severe weather of last January.

No Ships for Coal Exports

Tonnage that will permit of any extensive forwardings by the Coal Export Association, probably will not be available during the next ninety days. The charter for the association has been applied for and it will be possible to begin shipments at an early date if the tonnage could be secured. Food is being exported at the rate of 1,000,000 tons a month, which, with the turning back of the Dutch vessels, gives little promise for the allotment of ships for coal exports. The operations of the new association will be begun at Hampton Roads.

There arrived at Rio de Janeiro, Brazil, during October, 1918, reports Vice-Consul R. P. Momsen, 16,033 metric tons of foreign coal (all American fuel), as compared with 25,396 tons (19,365 tons American, 6031 tons British) in the corresponding month of 1917 and 51,814 tons (all American) in October, 1916. For November the imports amounted to 18,282 tons (12,842 tons American, 5440 British), contrasted with 27,488 tons (22,697 tons American, 4791 British) in November, 1917, and 77,121 tons (American 65,341 tons, British 11,780) in November, 1916.

Anthracite for Scotland

In a recent communication Consul H. D. Van Sant, Dunfermline, stated that the question as to whether anthracite is suitable for the open grate fire—almost in universal use in Scotland—is now being seriously considered, owing to the soft-coal scarcity, though there is still considerable doubt expressed as to its practical utility in relieving the coal shortage situation. Its advocates claim that this coal can be used with good results in an ordinary open grate, and that those who can purchase anthracite or who may have it in stock are in a position to secure an ample supply of heat during the winter by adding a small portion of the rationed supply of coft coal. The fires must always be started with ordinary soft coal, then the anthracite coal added when the soft coal is well alight.

Scottish anthracite is claimed to be more bituminous than Welsh coal and not so plentiful, being found in such thin seams that, owing to the present lack of miners, it would not be profitable nor possible to mine it to any great extent. American anthracite is said to be a much better quality than the Scottish, but the price is practically prohibitive.

In case the effort to introduce anthracite throughout Scotland is successful, and the future price of American anthracite is sufficiently low to meet competition, the question of the introduction of American hard coal in this soft-coal-producing district is an interesting one and worthy of consideration by American coal exporters.

New Brunswick Coal Imports

The report of the Fuel Administrator of New Brunswick, Canada, shows that of the total allotment of 77,140 tons of anthracite made to the Province by the United States Fuel Administration for the fiscal year ending Apr. 1, 1919, a total of 46,334 tons was used during the eight months ending Nov. 30, 1918. In addition to this it is estimated that 700 tons have been imported into the Province which have been obtained through jobbers, not operators.

There is no change reported in the South American port strike situation. Latest advices state that more than 180 vessels are being held in the harbors of Buenos Aires, Montevideo, Bahia Blanca and other ports on account of the strike. The vessels have a tonnage of 550,000.

One of the principal imports at the port of Santander, Spain, in normal times is coal, which is needed in the province for the railways, gas companies, electric-light plants, metallurgical works, domestic use, etc. In 1914 the demand for local use was about 150,000 tons, and came from England. Since the war started but a very small proportion of this quantity has been received. Efforts are being made to increase the production of domestic coal, although up to the present time supplies are limited and not satisfactory, and many industrial works were obliged to curtail or close up completely on account of scarcity.

Coal and Coke News

Harrisburg, Penn.

Representative McIntyre has introduced in the House a bill providing that every corporation doing business in Pennsylvania shall deposit with the Bureau of Statistics in the Department of Labor and Industry a sworn list, giving the following information: Its capitalization, bonded indebtedness, physical value of each corporate holding, gross income, gross expenditures for the fiscal year preceding the making of the list, and how the expenditures were proportioned between labor, capital taxes, improvements and repairs; and further, provides for the regular filing of a list giving the names and addresses of all stockholders and shares of stock held by each.

Representative Glass, of Philadelphia, has introduced a bill in the House which provides that the Governor be authorized to appoint a commission to make an inventory of the food and fuel products of the state. This bill covers both anthracite and bituminous coal. The bill of 1915 provided only for a commission to investigate anthracite coal, but the present bill is much wider in scope. The proposed commission will be authorized to investigate the question of the reduction in the cost of fuel and empowers the commission to provide for the proper and equitable distribution of food and fuel, and to fix a maximum price therefor; also to confiscate any food or fuel products in the possession of individuals or corporations refusing to sell at prices fixed by the commission.

The Governor is authorized to appoint a commission of nine citizens of the Commonwealth. Two of the commissioners shall be members of the present House of Representatives and two shall be members of the present Senate. The sum of $25,000 is asked for the use of the commission for the purpose of carrying out the provisions of the proposed act.

Representative Goehring has introduced in the House an amendment to the act of June 2, 1915, which established an elective schedule of compensation and procedure for the determination and compensation under the Workmen's Compensation law. The amendment calls for "Serious and permanent disfigurement of the head, face or hands, 50 per cent. of the wages during 215 weeks."

Uniontown, Penn.

Interest in the Connellsville coal and coke trade just now is centered upon contracts made for the first half of the present year upon the basis of the Government price of $6 per ton, coke, at ovens. That phase has been before the trade since Feb. 1, when Government prices were removed, and it is now believed that agreements have been reached upon all contracts that will be revised.

Revision of contracts calling for the Government price have ranged down as far as $5, with some at $5.50, but the largest independent coke operators have yet in force the original $6 contracts and there seems little likelihood of any more revisions as regards prices although quantity of delivery has been sharply reduced. In one instance of a revised contract upon a basis of $5, the furnace operator agreed to submit cost sheets to the coke operator at time of settlement. If at that time he could show that it was unprofitable for him to operate his furnace with coke at more than $5, the coke operator agreed to sell him coke at that figure. On the other hand, if a profit was shown by the cost sheets the price of coke was to be advanced accordingly.

There is a unanimity of opinion that the stabilization of the region upon a fixed basis during the present period of uncertainty was reached this week. The region is now operating at a 50 per cent. basis with a four- and five-day run the general rule. Operators in many instances have organized their plants for a five-day run by placing ovens on the inactive list and operating the others continuously. There has as yet been no employment problem in the Connellsville region, all workmen being given restricted employment.

Charleston, W. Va.

The output of coal in the Kanawha region during the week ending Feb. 15 was smaller than for the previous week. Innumerable mines throughout the district are shut down. As the month grows older there appears to be no improvement whatsoever, more and more mines having been shut. Kanawha producers are not so optimistic as they were a few weeks ago.

New River mines continue to be affected insofar as their regular, continued operation is concerned by tidewater congestion, and while a limited tonnage is moving to western markets, it has not been sufficient to make up for the loss of eastbound coastwise tonnage. The effect of such conditions during the week ending Feb. 15 was of course to hold down production to an appreciable extent. The claim is made that New England needs coal but is waiting to place orders in the hope of securing better prices. Some of the largest producers in the New River field have simply discontinued operations. Consequently, not only are a large number of mines shut down, but there is much idleness and the Bolshevik spirit is more or less rampant.

Production in the Guyan or Logan mining district dropped to 96,363 tons for the week ending Feb. 15, only a little more than one-fourth of the full-time capacity of the whole district. The district has been hard hit by present market conditions.

During the first half of February the mines of the Pocahontas district felt the effects of a waning market severely. Up until Feb. 1 production held up remarkably well, but it has now dropped to 279,151 tons, a decrease of over 100,000 tons, the last report showing an output of 385,000 tons. Such a slump, of course, was caused by a restricted market. Production would have been even less had it not been for the fact that it was possible to utilize part of the coal produced in the manufacture of coke, the coke production having been doubled from 46,000 tons to 82,379 tons.

Still further increases in the number of idle mines on the Monongah division of the Baltimore & Ohio and, in fact, throughout the twelve or thirteen coal-producing counties in northern West Virginia, were observed during the week ending Feb. 15. At that time on the one division the number of idle mines totaled 181. As there are 215 mines on that division, only 35 mines were operating. The same was true throughout the whole northern region. Production was virtually at a standstill and even where mines had not shut down coal was accumulating in cars unconsigned and therefore subject to demurrage, which has been mounting very rapidly throughout the northern section.

New York, N. Y.

To have a full and free discussion regarding the situation in which anthracite industry finds itself there was a gathering of operators and distributors in the Whitehall Building last Friday afternoon (Feb. 21), but at its conclusion it was stated that no definite plan had been outlined. Every person present agreed that the coal market at present is in a bad condition; and that owing to the warm weather, the supply is greater than the demand.

It was also stated that there was no effort being made to change prices from what they now are, and that it was generally agreed that the industry must be put back on a normal basis. In the meantime, it was stated, every individual concerned will try to work out his own salvation.

At the mining session of the annual meeting of the American Institute of Mining Engineers held here last week, S. D. Warriner, president of the Lehigh Coal and Navigation Co., in discussing mining conditions said that more than 60 per cent. of the coal now being sent to market is sold at a loss. Along these lines Mr. Warriner stated that with the reëstablishment of commercial conditions the prices arbitrarily fixed disappear, the result being financial operating loss to more than 60 per cent. of the industry.

The consumer, Mr. Warriner said, would not be especially interested in this phase of the situation were it not that with the indefinite closing down of high-cost operations, which is now taking place, the capacity of the anthracite mines is below the average annual production needed. This will inevitably tend to create a shortage unless coal can be stored by the companies for future use. Storage, however, is only economically practicable when there is stability of market conditions, otherwise the expense and risk make it prohibitive. For this reason the trade policy of the industry has been so far as possible under existing laws, to promote stable conditions by the summer discount in price, thus encouraging the consumer to store a portion of his winter supply, the operator storing the rest. By this method steady operation of the mine was insured and the annual supply required by the market obtained. For a number of years the anthracite industry would otherwise have been unable to supply the market requirements.

Today, continued Mr. Warriner, the anthracite industry is left by the Fuel Administration under the handicap of inadequate prices, a wage structure still under Government control and a tendency toward declining prices in all commodities, with the problem of recreating the stable commercial condition necessary to the prosperity of the industry as well as to the comfort of those who are dependent on anthracite for fuel.

Others who spoke along similar lines were R. V. Norris, who predicted an increase in the price of coal; Edwin Ludlow, vice-president of the Lehigh Coal and Navigation Co., who discussed conditions under which operators worked during the war and who stated that increased wages meant decreased ambition; and J. B. Neale, of Thorne, Neale & Co., who outlined some of the work accomplished by the Fuel Administration.

Victoria, B. C.

C. A. Magrath, Fuel Controller for Canada, has announced that the control of coal prices in British Columbia by the department of which he is the head ceased on Feb. 11 last. The collieries therefore are put back on the old competitive basis.

A. I. Fisher, member of the British Columbia Legislative Assembly for Fernie District, delivered an address in the House recently deploring the waste existent in the Crowsnest Pass coal fields in the manufacture of coke. He declared that it was a pity that the byproducts of the coal continued to be driven off into the air by the use of the obsolete beehive ovens. It was only a matter of chemistry, he declared, and the application of such measures as could be defined by experts which would permit British Columbia to profit by the manufacture of many commodities which, in pre-war days, were held as monopolies by other countries.

A bill has been introduced to the British Columbia Legislature providing for the application of a 44-hour week to all industrial workers of British Columbia. Its sponsor is James Hawthornthwaite, the member for Ladysmith, B. C. There are on the statute books of British Columbia two acts passed in 1918 through the instrumentality of Hon. William Sloan, Minister of Mines. One sets the hours of labor for all employed above ground in connection with coal mines of this Province at eight hours, thus placing this class of employee on the same basis as underground workers, except that the working day of the latter begins the moment they leave the surface. The other gives miners engaged in metalliferous mines, above or below ground, the eight-hour day. Both these enactments are effective on Mar. 31, 1919. If Mr. Hawthornthwaite's measure is indorsed, therefore, it means that in addition to the eight-hour day the miners of British Columbia will have a half holiday on Saturday.

PENNSYLVANIA

Anthracite

Beaver Brook—C. M. Dodson and Co. are preparing to take out the coal from their latest stripping proposition, a Wharton vein working, on the southern boundary of their property. They have recently completed a machine shop, replacing one damaged by a mine cave.

Jeanesville—Mine workers' officials are trying to arrange with the Lehigh Valley Coal Co. officials to give the suspended miners at the Jeanesville and Yorktown collieries their share of employment so that they will not be discriminated against. While the operations have been indefinitely shut down, the miners are urging that the company rescind its order to the extent of permitting work for three days a week.

Hazleton—Declaring that the steady pull at the mines during the past three years was extraordinary, managers of the big coal companies in the Lehigh field said that the present slackness in the trade would give them a long-sought opportunity for making necessary repairs. It was not thought possible that the big plants could be kept going much longer without breakdowns, but not one mine in this section had to close on account of accident.

Port Blanchard—A new washery has been completed by the Pennsylvania Coal Co. at No. 14 colliery and will be in operation some time during the summer. The washery will have a capacity of 500 tons a day and will be operated by steam. The plant was ready for operation Jan. 1, but on account of the mild winter the demand for anthracite decreased to such an extent that it was not deemed advisable to begin preparing coal until later in the year. Men from No. 14 colliery will operate the washery.

Jeddo—The G. B. Markle Co. has cut the price of coal to its wagon trade 75c. per ton in accordance with the passing of the Fuel Administration's price restriction. The company is storing coal in underground chutes and on the surface, and is working a normal schedule. A worker engaged in storing coal was drawn into an underground chute and, after an exciting experience, was rescued unhurt.

Miners employed by J. S. Wentz & Co. and the Upper Lehigh Coal Co. were cutting coal on idle days and making full-time pay. Their action was resented by the transportation employees, and their local unions have ordered all idle-day coal-cutting stopped.

Bituminous

Brownsville—The Rich Hill Coke Co., operating a mine and 150 beehive coke ovens 12 miles east of Uniontown, on the Baltimore & Ohio R.R., has closed down indefinitely on account of lack of business.

Connellsville—The H. C. Frick Coke Co., which for the past few weeks has been operating its plants only four and five days a week, will put half its plants in this region back to six days a week. The other half will be operated five days.

Leisenring—The du Pont Powder Co. is erecting two large storehouses and distributing stations here to relieve the overwork at its Fairchance and Leckrone stores. The new stores are in charge of A. W. Matthews. The explosives will be distributed from this point by motor trucks.

Scottdale—James Wardlaw, of this city, has organized a mining class at the Dearth mines to instruct several mining men in questions and current topics on mining to prepare them for the annual mine foreman's examination, which will be held in April. The mining class meets two days each week.

Tarentum—The West Penn Power Co. is preparing to open a large mine in Allegheny County on the Allegheny River near Tarentum (on the Allegheny Valley division of the Pennsylvania R.R.) to supply coal for the large power plant it is building at Springdale, nearby. It will be a shaft operation in the Freeport coal.

Somerset—On account of the increasing coal traffic in the Somerset District, on the Baltimore & Ohio, the railroad company has moved a large portion of the Meyersdale employees to Somerset and will work these crews from the new division headquarters here. This will move about fifty families to this place from Meyersdale.

Somerset—The Pennsylvania Smithing Coal Co. has purchased the Adams mine near here, formerly owned by S. M. Hamilton & Co., of Baltimore. The entire property was purchased a few months ago by Charles F. Roy and others, of Somerset, who made the sale to the Pennsylvania company. The property includes about 1200 acres of coal and all improvements, tipple, houses, etc. It is located on the Somerset & Cambria branch of the Baltimore & Ohio and is opened in a seam of coal that has not been developed at any other point.

Uniontown—Development of the Fuller tract of coal in Perry township to an eventual capacity of 2000 tons daily will be commenced at once by the Jamison Coal and Coke Co., which recently purchased 575 acres at a little more than a million dollars. The company has recently acquired the plant of the No. 3 opening of the Washington Coal and Coke Co. and will use that plant as an outlet for the Fuller field. Another outlet is now situated on the opposite end of the field and a restricted tonnage has been taken out during the past few months. The entire output of the Fuller field will be shipped in raw coal to the Bethlehem Steel Co. for its by-product plants. About 50 men are now employed at the new operation, engaged principally in erecting houses. Ten bungalows are under construction and more will be built when required. R. M. Pollack, formerly with the Washington Coal and Coke Co., is superintendent of the Jamison's new plant.

WEST VIRGINIA

Bower—Since last summer, when announcement of the company's plans were made in "Coal Age," the West Virginia Coal and Coke Co., has had under construction one of the most complete Y. M. C. A. buildings in the coal fields of West Virginia, at this place. The structure is now practically completed. Within its walls every provision has been made for the comfort, convenience and amusement of its employees.

Williamson—As a preliminary step toward engaging in extensive development of the large area of coal land recently purchased from the Kountz Bros. estate of New York, the United States Steel Corporation has a corps of engineers going over the property.

Work has been completed on a new tipple erected by the Standard Thacker Fuel Coal Co. A number of other improvements have also been made by the same company.

A new tipple is being built by Goodloe Brothers on their leased tract of coal at the mouth of Pond Creek near Williamson.

Philippi.—William Taylor George, on behalf of himself and associates, has sold to the Raccoon Coal and Iron Co. the following mines: Randolph Smokeless Coal Co., the Joseph Hart land on Rich Mountain, 2500 acres, $250,000; the T. J. Jones tract of 35 acres at Wilmoth for $50,000; the Maranz Coal Co. at Middle Creek, in Clay County, $60,000, and the Clay County Fuel Co., near Hartland, $65,000, making a total of $425,000. This is one of the biggest deals in this section of West Virginia in a long period.

INDIANA

Terre Haute—The average number of mines idle in Indiana daily is 52. The approximate number of miners who are out of employment is 10,000. In the Terre Haute field there are 42 mines, half of these being idle, throwing 2000 men out of work.

Clinton—Joseph Colan was brought before Justice of the Peace M. L. Casey on a charge of opening a keg of powder with a pick. Colan is a miner employed in the Clinton fields. He pleaded guilty and was fined $1 and costs, amounting to $8.75, which he paid. Colan claimed he did not know he was violating any law.

Petersburg—The Pike County Coal Co., with head offices in Chicago, which recently leased 5000 acres of coal land in western Pike County and eastern Gibson County, has a number of testing rigs at work on its leases and as soon as the tract is thoroughly tested two new coal mines are to be located near Oatsville, nine miles west of this city. The mines will be connected with the Evansville & Indianapolis R.R. by switch from Littles, and will follow the Patoka River to a point near Oatsville and then extend north to where the new mines are to be located. The switch will be built this summer. The Pike County Coal Co. owns the Atlas No. 1 mine in this city, and in March will start the erection of a steel tipple capable of handling 4500 tons per day, which will make it the largest mine south of the Baltimore & Ohio R.R. in Indiana. Just east of Spurgeon, during the past month, 3500 acres of coal land have been leased and bought, and a number of stripping mines are to be operated on this land during the coming year.

ILLINOIS

Pana—Members of the four Pana locals of the United Mine Workers, alleging that the charges made by undertakers for burial of members are extortionate, are taking steps to organize an undertakers' coöperative association, to membership in which all citizens of the township as well as the miners, will be eligible. The miners in their statement assert that they have been unable to reach any agreement with Pana undertakers for burials at reasonable prices.

Pekin—Satisfied to leave whatever grievances they may have for settlement with the proper officers of their organization, all of the 500 mine workers in the employ of the Groveland Mining Co. have returned to their work. Pending the settlement of the controversy, which resulted over the refusal of the men to work under Clait Maupin, top boss at Groveland Mine No. 1, the resumption of mining was renewed and from all outward appearances no strike or trouble of any sort is evidenced in any part of Wesley City.

Edwardsville—It is said that work will be started within a few days on the most modern coal-mining plant in Madison County. The Donk Brothers Coal and Coke Co., of St. Louis, is putting down the mine. It will mean the expenditure of approximately $500,000 and will give employment to 700 men when running at full blast. After the mine is in full operation the owners expect it to produce 5000 tons of coal daily, making it a rival to any mine in southern Illinois. The Allen-Garcia Co., of Chicago, has the contract for the work. The coal and air-shafts will be sunk simultaneously. Grading will be begun within a few days and the sinking of the shafts will be started Apr. 1. It is hoped to hoist coal by July 1. The coal shaft will be about 12 x 32 ft. making a double hoist of 12 x 16. This will permit large cages carrying coal cars with a capacity of three tons each. It has not been decided yet whether the company will erect houses for the workmen or whether the City of Edwardsville will have to look after this matter. Walter Clark, of Collinsville, will be the superintendent of the new mine. The Donk Brothers Coal and Coke Co. has been operating shafts at Collinsville, Maryville and Troy. The company has some mines which are well worked, and the new mine is to take the place of these.

ALABAMA

Risco—The new coal washery, crushing and screening plant of the Republic Iron and Steel Co. at this place, is nearing completion and most of the units will be placed in operation within the next two weeks. The haulage will be changed over to the new slope, from which a greatly increased tonnage will be taken.

OKLAHOMA

Broken Arrow—Tulsa County, Oklahoma, produced in 1918 a total of 200,000 tons of coal, according to figures prepared by Garland Marrs, president of the Seneca Coal Co., which is now opening a mine at this place. It is believed that this total will be exceeded in 1919, as mining operations are being carried on on a much larger scale. The Sand Springs Railroad Co. is preparing to build a railroad line from Tulsa into the new Broken Arrow field, which will mean the immediate development of this promising area. None of the companies operating in Tulsa County have yet found it necessary to limit their operations.

Foreign News

Vancouver, B. C.—The British Columbia Chamber of Mines is busy organizing an international mining convention to be held Mar. 17, 18 and 19.

Victoria, B. C.—The immediate future of coal industry in the Merritt (B. C.) field is reported to be uncertain. For some time the Canadian Pacific Railway Co. has been taking a considerable proportion of the output of that field for steaming purposes, a use to which the coal is well adapted. Recently it has been necessary, according to the operators, to increase the selling price because of the demands of men for more wages and the generally high cost of production. The company, apparently, does not care to pay at the higher rate and has cancelled its contract. If some arrangement cannot be made to continue the former business relations it is predicted that the collieries affected either will be forced to close down or to materially curtail their output. Hon. William Sloan, Minister of Mines, has been asked to assist in the effort to reach an adjustment of the difficulty, to which he has acquiesced; but whether the representations which have been made through him, as well as from other sources, will be effective is doubtful at the present moment.

Personals

J. C. Douglass is superintendent for the Dor-Mar Coal Co. at Savan, Penn., taking the place formerly held by **William Reid,** resigned.

C. W. Stafford has resigned his position as chief engineer of the Pond Creek Coal Co. and has opened a mine efficiency engineering office in Huntington, W. Va.

Albert Dally, Knightsville, Ind., has been appointed assistant mine inspector by the State Industrial Board, to succeed William Moore, of Terre Haute, resigned. Mr. Dally is a member of the United Mine Workers of America, District 11.

Herbert G. Parker, for many years with the Pittsburgh Coal Co. and recently Assistant Manager of Railroad Fuel Distribution, United States Fuel Administration, has been appointed sales manager of the coal department of the Iron Trades Products Co., Pittsburgh, Penn.

Lieutenant-Colonel Lloyd G. McCrum, who has been manager at the Rock Island Arsenal, has been discharged from the service and has returned to New York to his old position as manager of the W. H. Bradford Co. Mr. McCrum will also remain associated with the Victor Coal Mining Co. at Somerset, Penn.

J. Corbus Bushnell, formerly associated with the Business Men's Clearing House, Chicago, Ill., and until recently connected with the U. S. Employment Service as special agent to examine the personnel methods in vogue at Vickers Ltd. and Woolworth Arsenal, England, has been engaged by the General Engineering Agency, Pittsburgh, Penn., as personnel director.

A. S. Learoyd, during the past year Director of Distribution of the United States Fuel Administration, has been appointed assistant to the president of the Lehigh Coal and Navigation Co. Prior to Mr. Learoyd's connection with the Fuel Administration he was for many years employed as general freight agent by the Delaware, Lackawanna & Western Railroad Co.

Walter E. Hoots, formerly Northwestern sales agent for the Macon County Coal Co., of Decatur, Ill., with headquarters in Waterloo, Iowa, has resumed his position with this company after a year in the Navy. Mr. Hoots was discharged from the service in Boston the first of February, serving as a radio electrician at the U. S. Naval Radio School at Harvard University and aboard the battleships "Alabama" and "Kearsarge."

Wyman Eaton has been appointed chief engineer of Freyn, Brassert & Co., engineers, Peoples Gas Building, Chicago, Ill. Mr. Eaton was formerly connected with the engineering offices of Julian Kennedy, Youngstown Sheet and Tube Co., William Tod Co., Corrigan McKinney Co., and has recently resigned his position of engineer in charge of the rolling mill work of the Mesta Machine Co. to take up his new duties.

Lieutenant George Conway of the 27th Engineers, U. S. A., is in the General Hospital at Fort Douglas, Salt Lake City, Utah, recovering from an operation due to an injury received in France. Before enlisting as a private, Lieutenant Conway was assistant to A. C. Watts, chief engineer of the Utah Fuel Co. During a large part of his service in France, Lieutenant Conway was attached to the British Royal Engineers as a mining expert.

H. M. Crankshaw, general manager of the Cranberry Creek Coal Co., operating the Cranberry and Harwood collieries, has resigned and will return to England, where he will enter the engineering firm of which his father is the head. Mr. Crankshaw will be succeeded by **J. P. Warner** of Lansford, Penn., who was one time chief mining engineer for the J. B. Markle Co. at Jeddo and has been with the Lehigh Coal and Navigation Co. for some years.

Obituary

J. R. Richardson, engineer for the Black Mountain Coal Corporation, Evarts, Ky., recently died of pneumonia at the Harlan County hospital.

Wallace H. Rowe, president of the Pittsburgh Steel Co., and affiliated with other large corporations, died Feb. 1 at his home in Pittsburgh following a lingering illness. Besides being actively interested in a number of steel companies Mr. Rowe was also president of the Monessen Coal and Coke Co.

Harrison W. Matters, vice president and secretary of the J. Woolley Coal Co., Evansville, Ind., died Feb. 13 from a rare disease which involved a gland in his back. He had been confined to St. Mary's hospital, Evansville. Mr. Matters was first associated in the coal business with Jabez Woolley, following a period of railroad service. He was born at Vincennes, Ind., and was a graduate of De Pauw University, Greencastle, Ind.

Industrial News

New York, N. Y.—There was a well attended meeting of anthracite jobbers at the Whitehall Club on Tuesday of this week (Feb. 25) at which the matter of demurrage charges was discussed.

Pinesville, Ky.—Richard M. Lambert, receiver for the Calvin Coal Co., Pineville, in proceedings brought by the Matthew Addy Co., Cincinnati, Ohio, has filed notice that all claims must be presented by Mar. 3. Mr. Lambert has headquarters in the First National Bank Building, Cincinnati.

Milwaukee, Wis.—The Sterling Wheelbarrow Co. is manufacturing a wheelbarrow that has ten spokes instead of eight. The company states that this is an important improvement in the design of wheelbarrows, as the two additional spokes help greatly to strengthen what is the weakest part of the average barrow.

Chicago, Ill.—The Under-Feed Stoker Co. of America announces that it has removed its general offices from the Harris Trust Building, Chicago, Ill., to the Book Building, Detroit, Mich. This change will not interfere with the sales work of the concern's Chicago district sales office in the Harris Trust Building nor any of its other district offices.

Indianapolis, Ind.—The State Senate has passed Bill No. 79, introduced by Senator Bainum, providing for an increase in the salaries of the state mine inspector and his assistants. The first noted will receive an annual compensation of $2500, and the deputies $1800 each per year. The bill also provides for an increase in the present number of deputies.

Chicago, Ill.—The Chicago Pneumatic Tool Co. announces the removal of its Cleveland district office from Room 813 to Rooms 406-408 Engineers Building, effective Mar. 1. The new headquarters will provide excellent facilities for giving the best possible service to the company's expanding interests within the Cleveland district. Ross Watson is district manager.

Beckley, W. Va.—Subject to the action of the stockholders at a meeting to be held here on Feb. 27, the capital stock of the Hawley Coal Co. will be increased from one thousand to five thousand shares, so as to permit of the company taking over the leasehold, equipment and assets of the Combs Coal Co. At the same time it is proposed to change the name of the Hawley company to the Big Sewell Consolidated Coal Co.

New York, N. Y.—Delos W. Cook, state fuel administrator announced on Feb. 22 that on Mar. 1 the office of Federal Fuel Administrator for the city and State of New York will be closed and that this action automatically retires from office all county fuel administrators. Mr. Cooke in his order expressed his great appreciation of the coöperation of the public. Mr. Cooke, who assumed the duties of state fuel administrator last August, was at that time one of the vice presidents of the Erie Railroad Co. He succeeded in office A. H. Wiggin, of the Chase National Bank, who resigned in May last.

Charleston, W. Va.—Casualties in West Virginia mines in January reached a total of 28. As is usually the case, the largest number of such deaths were due to falls of roof, 28 losing their lives in that manner. Two met death through mine-car accidents and three through motor cars, while electricity killed one other. One man was killed in a premature explosion and two in handling explosives. There were five deaths outside the mines, two of which were caused by mine cars, three resulting from miscellaneous causes. McDowell had the largest number of accidents—seven—and Logan the second largest—six.

New York, N. Y.—The Pulverized Fuel Equipment Corporation has recently been organized for the purpose of taking over the business of the Locomotive Pulverized Fuel Co. The latter company had developed the "Lopulco" system for the preparation, distribution, storage, feeding and burning of pulverized fuel for steam generating and heating purposes. The officers of the Pulverized Fuel Equipment Corporation are: J. S. Coffin, chairman; J. E. Muhlfeld, president; H. F. Ball, vice president executive; H. D. Savage, vice president in charge of sales; V. Z. Caracristi, vice president in charge of engineering; S. G. Allen, secretary and treasurer.

Decatur, Ill.—The Decatur Association of Commerce has called a meeting of the large users of coal in this city for the purpose of ascertaining why Decatur factories and industries do not use Decatur coal exclusively. It is estimated that as much as 4000 tons of coal are shipped into Decatur each week, and the committee from the Association of Commerce figures that if all Decatur industries would use local mine coal that 160 more miners would be employed, which would increase the pay-roll to at least $275,000. The mining of coal used by one factory alone, if done in the Decatur field, would give employment for seventy more miners.

Huntington, W. Va.—Two hundred and fifty coal operators, representing practically every operation in the mine fields of southern West Virginia, eastern Kentucky and a part of Tennessee, have completed plans for the organization of the Central Coal Association. Colonel E. O. Dana, of Cincinnati, was elected president of the association, and Mr. Rodgers, of Pikeville, Ky., was elected treasurer. A board of directors was appointed by Colonel Dana, and the selection of a secretary will be made later. The headquarters of the association will be in Cincinnati, where the next meeting will be held Mar. 4. One of the main purposes of the new association is the publication of reports which will give the average cost of producing and selling, together with the maximum and minimum prices.

Jefferson City, Mo.—A bill has been introduced in the Legislature which provides that railroad companies must weigh all carload shipments of coal at point of origin or the nearest point at which track scales are maintained, and again weigh such coal at destination, if there be railway track scales maintained by the railroad company at such destination. Where there are no track scales the consignee would have the right to have the coal weighed on wagon track scales, and the railroad company would be compelled to accept the sworn statement of the person in charge of the scales, subject only to a deduction of 10 lb. for each wagon load to cover variations and errors. The railroad company is required to deliver to consignee the original weighbill and expense bill showing the gross tare and net weight at each weighing. The penalties provided are from $100 to $500 for each offense.

Charleston, W. Va.—Final action has been taken on the Hale Bill, originating in the House of Delegates, increasing the number of district mine inspectors in the state from 15 to 19 and their annual salaries from $2100 to $3000 per year. The measure also increases the salary of the chief of the department from $3600 to $5000 a year, and recreates the department so as not to run counter to the constitution of West Virginia. The bill makes no other changes in the mining laws of the state. Both houses have now acted on the Hale bill. There is a bill known as the Blizzard bill which has passed the House of Delegates and which provides that scales shall be installed at every mine where ten or more men are employed, and that all miners shall be paid by the actual weight of the coal mined. There is a proviso, however, that upon petition of half the miners in any mine scales may not be required.

New York, N. Y.—Charles S. Allen, secretary of the Wholesale Coal Trade Association has addressed a letter to each of its members asking expressions upon a number of propositions in order that the views of the members may be used as a guide to the course to be taken by the association upon the subjects. Some of the propositions are: Do you approve of filing sales contracts as suggested by other associations or in modified form; Shall the Coal Exchange be continued or discontinued temporarily; Shall the association take action with respect to matters of public interest; Do you approve of the proposed bill to restrict immigration for four years; Do you approve of the use of uniform contract forms; Will you support adoption of use of trade acceptances; Will you support a bureau of credit information by giving the information with respect to your customers; Do you approve of adoption of net ton basis for freight rates in order to place sale of coal on net ton basis; and, Do you propose to use the Tidewater Coal Exchange after March 1.

MARKET DEPARTMENT

Weekly Review

Operators and Consumers Waiting—Feeling That the Worst Phases of the Bituminous Situation Are Over—Stocks Dwindling and Production Falling Off—Anthracite Situation Still Deplorable—No Signs of Improvement

IF ONE wanted a phrase to convey tersely the present status in the coal market, he could do no better than choose the one made famous before our entry into the world war—"watchful waiting." Unlike other industries, the coal mines cannot store their product against the time when demand becomes active and an urgent call for fuel is again manifested. If the public does not buy coal, the mines cannot operate. Coal cars on railroad sidings the country over stand loaded with coal, all awaiting a market that is slow to materialize. It is inconceivable that this condition can long continue.

Reserve stocks in the hands of consumers are daily growing smaller. And speaking of reserve stocks, it is rather mystifying how the so-called non-essential industries, which were presumably receiving no coal whatever during the critical period, were discovered with large accumulations of fuel when the armistice was signed. But why uncover the family skeleton? Reserve stocks cannot last forever. Already many of the well informed in the bituminous branch of the coal industry profess to see a rift in the clouds, and a feeling of optimism is fast dispelling the gloom.

It cannot be denied that the closing down of the soft coal mines, with the consequent decrease in output, has served immeasurably to pull together the strings on what promised to be a loose market. Prices are holding well to the former Government maximums, and there is not the slightest indication whatever of a definite price-cutting policy. Most of the coal moving is in fulfillment of contracts made many months ago, few purchases of spot coal being reported.

With the nearing of the new coal year and the time for the making of new contracts, it can be stated that the worst part of the depression from which the bituminous industry has been suffering is over. In fact it would occasion no surprise if market conditions from now on should change for the better.

Production of soft coal during the week ended Feb. 15 is estimated at 7,761,000 net tons, a decrease of 3,887,000 net tons compared with the same week of 1918. (How the mighty have fallen!) The production for the coal year to date is estimated at 509,775,000 net tons, exceeding that of last year for the same period by 27,149,000 net tons.

The hard coal industry is still groping in darkness. In spite of the fact that many of the anthracite collieries have shut down, while others are working only part time, considerably more coal than the market can absorb is reaching tidewater. Domestic sizes are plentiful, thanks to an open winter, while the smaller steam sizes are glutting the market.

Retailers are not at all anxious to stock any more anthracite, preferring to clean up what they have in their yards while awaiting the schedule of summer prices. At this writing it is uncertain just what the future will bring forth in the hard coal market; there are no reassuring signs.

Anthracite production during the week ended Feb. 15 totaled 1,100,000 net tons, as against 1,444,000 net tons during the week of Feb. 8 and 1,854,000 net tons during the week of Feb. 15, 1918. The total production for the coal year to date now amounts to 84,907,000 net tons as compared with 87,383,000 net tons for the period Apr. 1, 1917, to Feb. 15, 1918.

WEEKLY COAL PRODUCTION

Bituminous—The production of bituminous coal during the week ended Feb. 15 is estimated at 7,761,000 net tons and is a decrease of 186,000 net tons compared with the week preceding and a decrease of 3,887,000 net tons compared with the same week of 1918. The daily average for the current week is estimated at 1,294,000 net tons as compared with 1,847,000 net tons for the coal year to date and 1,749,000 net tons for a similar period of last year. The production for the coal year to date is now estimated at 509,775,000 net tons and exceeds that of last year for the same period by 27,149,000 net tons.

Anthracite—Production during the week ended Feb. 15 is estimated at 1,100,000 net tons as compared with 1,444,000 net tons during the week of Feb. 8, and 1,854,000 net tons during the week of Feb. 15, 1918. The daily average per working day during the current week is estimated at 183,000 net tons and is equivalent to 60 per cent. of the daily average for the coal year to date and 58 per cent. of the daily average for the similar period of last year. The total production for the coal year to date now amounts to 84,907,000 net tons as compared with 87,383,000 net tons for the period Apr. 1, 1917, to Feb. 15, 1918.

Carriers' Reports—Reports received from the carriers for the week ended Feb. 15 show increased loading during that week over the week preceding in central Pennsylvania, Ohio, Tennessee and Kentucky, and the district including Iowa, Texas and the southwest States. Decrease occurred in all other fields, the southern West Virginia fields falling behind the most—1153 carloads or 8 per cent.

New England Shipments—Shipments of bituminous coal to New England during the week ended Feb. 15 are estimated at 240,971 net tons, as against 286,433 net tons during the week preceding. The rail receipts through the New England gateways were in excess of that of the preceding week, and amounted to 119,040 net tons, while tidewater shipments, amounting to 121,931 net tons, fell considerably below the shipments during the week ended Feb. 8, which amounted to 176,369 net tons. All harbors report a decrease in tonnage loaded, with Hampton Roads falling behind the most. The tonnage loaded at this harbor, during the week ended Feb. 15, amounted to 59,637 net tons, as compared with 107,665 net tons during the week of Feb. 8.

Tidewater Shipments—Bituminous coal shipped from the North Atlantic ports and Hampton Roads, during the week ended Feb. 15, amounted to 526,085 net tons, as compared with 670,445 net tons during the week ended Feb. 8. Shipments during the week from Baltimore increased slightly, while shipments from New York and Philadelphia fell approximately 9 per cent. behind the tonnage shipped during the week preceding, and shipments from Hampton Roads amounted to but 58 per cent. of the tonnage shipped from the same port during the week of Feb. 8.

Beehive Coke—The production of beehive coke in the United States during the week ended Feb. 15 is estimated at 422,000 net tons, as compared with 501,000 net tons during the week ended Feb. 8 and 560,000 net tons during the corresponding week of 1918. The average production per working day during the current week is estimated at 70,000 net tons, as against 84,000 net tons, during the week preceding, and as against 93,000 net tons during the week of Feb. 15 of last year.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running considerably less than for the same week of 1918. Orders for immediate delivery from road salesmen were of greater volume than for the corresponding week last year. Fall lines have not yet been opened. More merchants were in the market seeking immediate requirements for stocks depleted by excellent retail business which still continues. Collections were satisfactory.

Dry Goods Economist—Purchases of the retailers during the week indicate that present conditions in the dry goods trade are exceptionally good. In New York and in Chicago wholesale houses it is noticed that retailers are buying for every department. This is taken to indicate the free movement of all lines of goods. As a rule the goods now being ordered are wanted at once, and in many cases it is evident that the ability to make immediate deliveries is regarded as of more importance than the possibility of the price being shaded at a later date.

American Wool and Cotton Reporter—Buyers of wool are having their difficulties in securing it from the foreign markets. In South America there has been labor trouble, and in South Africa there seems to have been delay in cablegrams. It is felt by some that after the London sale in April that the basis for the world market prices on wool will be more definite. The cotton market does not show very much activity. The surprise of the week was the January consumption report, which showed an increase of 15 per cent. or more over the previous month regardless of curtailment, labor unsettlement, etc.

Bradstreet's—While reports as to trade and industry have not greatly changed, the more cheerful feeling noted last week, particularly in the territory west of the Mississippi, is fully maintained, and in addition there are reports from larger eastern centers that price reductions in textiles have seemed to bring about freer trading. Proof that talk of enlarging export trade has had a really good and sufficient basis is at hand in the excellent export statement for January. Contributory to the spread of better feeling also has been the sustained and accentuated strength of the stock market, which has witnessed the retreat of a rather extended short interest, moved thereto by the favorable tenor of reports from the Peace Conference and the prospects that the movement for government operation or ownership of the railroads has been checked. Liberty Loan bonds have been aided by prospects of a change from long to short term issues.

Atlantic Seaboard

BOSTON

All-rail prices not so soft. Operators in most cases follow conservative policy. Recent Government bids reflect this tone. Railroad buying looked for only in a small way for the present. Tidewater shipments spasmodic from Hampton Roads, but dumping light at other ports. Shipping Board announces its lack of interest in New England coal freights. Shippers will get restive when any buying starts. No prospect of active market for months to come. Stocks apparently as large as ever. Anthracite extremely dull. Outside freights a notable factor. Company barges swinging at anchor, instead of rates being modified to meet conditions.

Bituminous—A slight change in the New England situation can be noted this week. There are fewer reckless quotations all-rail than has been the case since Jan. 1. Instead of prices on fair to good grades being ragged around $2.50@2.85 per net ton f.o.b. mines and $2@2.40 for inferior coals, quotations seem to have settled into grooves on a higher range, especially for those of better quality. This territory is still being closely canvassed for new business, but evidently the operators have taken a hand and made it plain to sales agents just what prices they would accept for current output. The result is all the better for the market, for the few buyers who are now interested will have more confidence. It is apparent also that even on the scattering business that is to be had there is more discrimination between grades. So much poor coal was dumped into this market last year that shippers are now obliged to state pretty exactly what coal is to be furnished. That the whole situation all-rail is slightly firmer is a good sign, and foreshadows a better market in general when other conditions improve.

The fact is that operators are today following a close-hauled policy, in most cases. In central Pennsylvania there are a lot of mines shut down, but those that are at all in operation are generally insisting upon remunerative prices. Operators who produce good to high-grade coal are holding to the recent Government figure, if they do not ask more, and while orders are few they are apparently willing to put out only one-fourth or one-fifth their usual tonnage rather than reduce prices, when they are not at all certain that lower figures would to any extent increase their tonnage. While they pursue this policy there will be some encouragement for the future of the market.

Recent Government bids confirm this attitude on the part of operators. The Watertown (Mass.) Arsenal, for instance, recently invited proposals to furnish 10,000 tons at the rate of two carloads daily from Mar. 10. The only bids were on coals that would appear on the Navy acceptable list; on one was quoted $3 per net ton and on the other 5c. less. Of course, it should also be stated that these coals had to be submitted on rather rigid specifications, but they will come near enough the limitations named so that there would probably be little correction in price for quality. These bids were somewhat of a surprise to the trade here, which had become accustomed the past two months to a much lower price level even on good grades.

The conference on Feb. 18 in Washington with regard to the coal-purchasing policy of the Railroad Administration has apparently had no direct result on the railroad fuel situation in New England. The tonnage in storage is still very heavy and any prudent management would come pretty near insisting that this coal be used before any comprehensive purchases are made. It is true, also, here as in other sections, that only a small percentage of the coal now being used is not covered by contracts made at a time when the Fuel Administration very strongly counselled such action. These are among the reasons why there will probably be only light buying on the part of the railroads for weeks, if not months, to come. The volume of traffic in this territory is still far from heavy and railroad consumption is much less than a year ago.

While a considerable tonnage is coming forward from Hampton Roads on contract the movement is irregular and spasmodic. One week may show quite an increase as compared with another, but the average is low, and the agencies are still wondering where coal is to be placed when current contracts expire. The textile mills continue on short time, and practically all the industries are using less coal than has been customary the past two years. The export market is not developing the way it was hoped, and except for Navy purposes current demand is light. Dumping at Baltimore, Philadelphia and New York is much less than at Hampton Roads, and in some of the pools there is no movement whatever. It is reported that 170 mines are shut down in the Fairmont district alone, and with current marine freights and the differentials in favor of all-rail delivery from central Pennsylvania, it is hard to see how there can be much improvement. The use of the Tidewater Coal Exchange ceases to be mandatory on Mar. 1, and it will be interesting to see to what extent the larger shippers withdraw from pooling arrangements.

Little is heard of prices on Pocahontas and New River, since practically all the tonnage coming forward to this market now is on last year's contracts. Market cargoes still meet with hard going, and it cannot be said that any of the grades ordinarily received here by water are being absorbed any better than has been the case since the year opened.

At last the Shipping Board has made a declaration of policy with regard to coastwise coal freights for the near future. During last week a stereotyped telegram was sent in answer to all inquiries and offers of the past 60 days to the effect that the demand for tonnage was so good in other directions that the Shipping Board "was not particularly interested in New England coal freights," and that rates on requisitioned tonnage would remain unchanged for the present. In other words, the owner of a steamer, 2500 tons and upwards D.W. capacity, "requisitioned" in 1917 by the Shipping Board, must charter at $3.50, Baltimore to Boston, or tie up his ship. The rate is mandatory, and no intimation is given of a possible change. While the steam trade is in its present posture there is perhaps no great injury being done, but once there is an active market for fuel there is sure to be some loud talking that will be heard at Washington. The whole rate situation needs revision, and such a revision cannot come too soon for New England, or there will be trouble next fall and winter.

The indication that there will be no active market for several months is one of the dangers in the present situation. Manufacturers now have such heavy supplies on hand it is quite within the range of possibility that they will overdo a non-buying policy. It is now very plain that operators intend to keep coal in the ground unless what they consider a fair price is offered, and should this general situation continue until June, as there are signs it may, there might be real difficulty about getting forward coal for those industries who will need volume shipments once they begin buying. This will be all the more complicated if the present glaring differential between rail and water delivery is allowed to continue.

Anthracite—The demand for domestic and all sizes of anthracite continues extremely dull. The retail dealers are having no business, partly because of the mild weather and partly because so large a share of the season's business was done last season while the scare was on. Without doubt another factor is the present scale of prices. No dealer will take on coal much in advance of actual need, so great is the uncertainty over what will happen in the spring. The trade seems to feel that although there is a program on the part of operators that calls for a 50c. advance over present prices by Sept. 1, it will be hard to make the public think any such advance is justified. Of course, it is the delivered price at this end that gives them most concern. The proportion moved by the all-rail route has very largely increased the past two years, but there is still a large tonnage that must be taken by water. It is the high range of water freights on anthracite as well as bituminous that gives many dealers much concern.

On Dec. 28 the Railroad Administration, after months of consideration, advanced rates on railroad-owned barges, although at the time outside transportation in the open market had begun to offer at less rates, due to the slackening demand. Now that owners of these outside barges are trying to get charters at rates that run from an even dollar to points like Providence from New York to $1.35 to Boston, while railroad-owned barges are still held at $1.75@1.80, the discrepancy is too great to enlist any buying of company coal to come in the higher-rate barges. The result is that the latter swing at anchor, mines are shut down, and retail dealers run on as light stocks as possible, naturally preferring the all-rail route for such current supply as they may need.

NEW YORK

Coal industry in serious condition. Operators fear the outcome and discuss remedies. Demand slackens and buyers hesitate. No prospects of spring improvement. The bituminous market stronger, following tidewater clean-up. Worst is believed to be over.

Anthracite—Conditions in the anthracite market are unprecedented. Tradesmen who have been in the coal business for years declare that the situation has never been equalled. "Dead" is the way the situation can be summed up in a single word. There is no demand, and there is no opportunity for salesmen to dispose of a few cars of coal even at a sacrifice.

Salesmen returning from their trips inland report "mountains of coal" in the retail yards. Bins are filled and most retail dealers have good-sized stocks on the ground.

That the industry is in a serious condition is reflected in the meeting of operators held here on Feb. 21, at which time the situation was thoroughly canvassed and remedies suggested.

"More coal than we know what to do with" is the way the situation is being sized up by many dealers, and notwithstanding the curtailment policy adopted by the operators there is too much coal being sent to market.

Operations which have been on about a half-time basis for a few weeks are working still less time now, but this does not appear to decrease dumpings at the local docks, which for the week ended Feb. 21 were 3732 cars, an increase of 323 cars over the previous week.

Efforts to send coal westward are not successful, as that section is well stocked. Similar reports come from New England, while on Long Island the dealers are flooded with coal.

There is no prospect of buying improving before operators make some definite announcement regarding spring prices. Many rumors are heard, but so far no definite announcement has been made.

Many reports are heard regarding price concessions. Quotations for so-called Independent coals in many instances are said to be 20c. below company schedule. Demand for the larger of the domestic coals is about evenly divided, with little moving. Pea coal is difficult to dispose of, although large concessions have been offered. Efforts to ship this size into the West have proved unsuccessful, dealers reporting full stocks.

The cut in production is having its effect upon the anthracite steam coal situation. Stocks are not burdensome, but there is plenty to meet all requirements and producers are storing considerable quantities.

The retail situation is quiet. Dealers report little business and an inclination on the part of consumers to refrain from buying in expectation of the usual spring discount. If it is not forthcoming it is unlikely that buying will be heavy this summer, and most consumers are likely to hold off until early fall before ordering their next winter's supply of coal.

Bituminous—Operators and shippers are in a better frame of mind regarding the situation. There is not so much gloom about and the opinion seems to be strong that the bituminous market has turned and the worst part of the depression is past.

There has been a general clean-up at the local tidewater docks, and while the immense surplus has not been entirely wiped out the quantity of coal on hand is not large enough to cause any further apprehension. Shippers are obliged to dispose of their holdings here at concessions below the former Government maximum

price, but quotations on coal at the mines are much stronger. Accumulations at the docks have been reduced and efforts are being made to prevent a recurrence of the former trouble, due in most part to overshipments.

Operators and jobbers report many more inquiries, the result of reduced stock piles and the nearness of the new coal year, when contracts expire and new contracts begin. So far neither operator nor consumer has shown any hurry to sign up for the next twelve months. Nearly every operator has a different view of the situation and, of course, wants to make the best terms possible. Consumers are not willing to sign up at the present high prices asked, believing they are going to get coal later in the season at less than the prices quoted now and are willing to take chances, feeling they have nothing to lose.

One form of contract heard of provides for a readjustment of prices every three months. This form has found favor among some tradesmen, while there are others who favor the flat price for the entire year.

Nearly every day reports are heard of various manufacturing concerns substituting oil for coal for generating power, and it is said that the plan is being considered by other industries.

Dumpings at the local piers for the week ended Feb. 21 were 6248 cars as compared with 5624 cars the previous week, an increase of 624 cars.

The retail price of bituminous coal in Manhattan and the Bronx was reduced 25c. per ton on Feb. 21, the price now being $7.25 per ton. This is the second change in retail prices put into effect by the retail dealers in these two boroughs since the removal of price restrictions by the Fuel Administration, the first reduction affecting anthracite coals.

PHILADELPHIA

Anthracite dullness continues. Collieries on short working time. Retailers say big business done for the season. Pea coal trade vanishing. Reason sought for lack of ordinary demand. Sales now all based on circular prices. Some little retail price cutting. Independents cut prices in few instances. Rumors of spring price advance. Buckwheat only steam size in demand. Bituminous very quiet.

Anthracite—With the collieries that produce the very best grades of anthracite shutting down two and three days a week for want of orders, it is probably unnecessary to go further in commenting on the condition of the market. That the largest operating company sees fit to advertise in the daily press that it is prepared to make immediate shipment of all sizes is another unusual feature for the month of February.

The dealers are being reluctantly forced to realize that their business is about over for the season, for the prospect of any prolonged spell of cold weather is not at all good with the first of March almost here. With the vanishing of their hopes for this month, many of them feel certain that March will surely bring numerous small orders that will help in reducing the very heavy stocks which they have on hand of all sizes and which they are anxious to move in the event of any spring reduction.

All the retailers are in a quandary as to why they have lost so much of their pea coal business, as there is scarcely a yard that is not over-supplied. The operators are also giving much thought to the question, and it is becoming a serious problem with some of them. We have this week interviewed some of the largest buyers on this subject, but they are unable to cast much light on the matter. There are some who claim the fault lies entirely with the size itself. It will be remembered that acting upon a suggestion of the fuel authorities, and in order to increase the tonnage for family use, the operators quite willingly changed the size of the screens thus permitting a larger percentage of buckwheat in the pea coal than was allowed by the old standard of preparation. This, some dealers say, has caused the customers to complain and refuse to continue to pay the prevailing high price for it; and they have in the meanwhile changed to chestnut, apparently with much satisfaction.

Other dealers, including some of the representative ones, insist the trouble rests solely with the price. They say it is unreasonably high and that the difference between it and chestnut is too small, which just now is $1.60 per ton on the delivered price. It is known that a number of the operators are listening with interest to both sides of the controversy, for it is becoming apparent that something must be done to improve the sale of pea coal if it is to continue to hold its high place among the family sizes. Undoubtedly they dread to look back to the old days when it was looked upon only as a steam size. Right at this time the independent operators are experiencing the most trouble with this size, on account of the cars standing at the mines loaded with this size accumulating demurrage and with no storage yards to dump it.

Just as every operator has adopted the same price, not forgetting that the middle houses' "brokerage fees" have also been abolished, so have the dealers pocketed the loss on all individual coal in stock, and announced the same rates to the public. These are based on company circular plus freight and the retained gross margin of $2.50 per ton.

To date there have been remarkably few instances of retail price cutting among the dealers, it being confined principally to those dealers who formerly indulged in this practice. However, it is noted that where the rates have been reduced they have not materially increased sales. The prevailing retail rates are egg $10.30, stove $10.55, nut $10.65, pea $9.05. Among the cutters the lowest prices offered are a flat rate of $10.25 for egg, stove and chestnut, with $8.50 for pea.

We hear that dealers located along the lines of the Pennsylvania Railroad complain because they pay a higher freight rate than their competitors along the lines of the Reading. Of course this made little difference in the historic months just past, but with business falling back into usual channels it now affords an opportunity for the retailers to claim a concession. No doubt some of the independent operators are willing to absorb the difference, and we know that some of them have cut far deeper into the so-called circular than this, but the companies have so far refrained from making any such allowances. Among the individuals we have heard of prepared coal being offered for as much as 50c. off circular, yet even at that price they find difficulty in placing coal. We know of a dealer offered pea coal at a liberal concession and who accepted it simply as a favor to the shipper, as he put it, because he had treated him right during the war. However, price cutting by the independents is far from general, as they claim they are doing business at a loss even at circular price on account of the short working time of their mines with the lessened production. Such concessions as are given are simply to move coal that is accumulating demurrage.

One amusing feature in making the trip around the offices of the retail trade is to hear the dealers actually admit they made money in the past year. During those strenuous days they made pitiful pleas for coal and gave one the impression that the cost of labor, etc., was taking up the entire gross margin. Now we hear them admit it was the best year they ever had, and judging from the remarks of quite a few, the war contained few horrors for them.

Naturally there is much speculation as to April prices. As a whole the trade seems convinced there will not be the usual decline. While no shipper will risk a definite statement to his trade to this effect, they appear to be giving that impression. Also is the feeling growing that prices will advance. Some high in the trade predict that commencing May 1, and taking the present circular as a basis, prices will advance 10c. a month for five months. As the labor question is one of utmost importance with all large employers, so it is to the forefront with the operators. We believe it is justly claimed that they cannot reduce prices and assume the loss; and to reduce the wages of the miner is a proposition fraught with much danger.

Practically all dealers anticipate going through a dull period, some claiming it may last until early fall. They intend to watch collections closely and avoid filling the bins of their customers during the coming spring and summer with next winter's coal and waiting for the money until they commence to burn it, as has often been done in the past.

Notwithstanding the poor prospect for the immediate future of the coal business we hear of a number of prospective buyers who are apparently anxious to embark in it, but there are no yards in the city for rent and few if any for sale. In the case of a yard sold recently, there were half a dozen real buyers in sight, five of whom were bitterly disappointed when they found the other fellow had got it at a good figure.

We know that most operators have been embarrassed by having coal standing at the scales and on demurrage for want of orders, which accounts for most of the low prices quoted. Egg, pea and the steam sizes are causing the most trouble here. What business there is continues to be chiefly stove and chestnut, but with all the salesmen on the street and showing unusual activity there is competition for every order.

In the steam sizes buckwheat coal is the only size for which there is any demand, and while the companies stick closely to the $3.40 prices many of the individual shippers are selling for less. Barley and rice are extremely heavy and the big companies continue to put fair tonnages into the storage yards on account of the lack of sales.

Bituminous—The market fails to gain in strength. All operators report their mines on short working time and consumers are loath to buy. Of course the heavy stocks on hand are being fairly well used up, still it will be months before anything like active calls for fuel will be made. Shippers of the better class of coal are insisting on the price of $2.95, or thereabouts, for their output, athough there are plenty of offers of $2.50 and even lower. The consumer, though, has learned much about coal and is quite dubious of the quality of coal offered at the low prices, as much of it is of most doubtful quality. For strictly blacksmith coal the price range is $3.25 to $3.50, with a fair amount taken.

BALTIMORE

Demand for soft coal continues flat and an oversupply of fuel at tide is still noted. Prices are weak and regulated largely by individual circumstances of sale. Government changes pending. No snap to hard coal selling.

Bituminous—There is little market for soft coal here. The supply at this point is excellent as to quality and more than sufficient as to quantity. It is one of those markets where it is difficult to quote a price range even as sales are largely dictated by individual sale circumstances. Probably the most interesting feature here is had in expected changes due to coming Government regulations being dropped. The shippers have been told that there will be an abolition of the no-consignment rule of the Fuel Administration after Mar. 1. This will enable coal to be reconsigned after reaching consignees here, where in such a market as the present it is not infrequently declined. The ordinary railroad switching charge would then be effective as compared with the present requirement under the "no-reconsignment" order that the coal be reshipped at the full mines-to-city rate with an added tax of a special shipment nature. That changes are due in the pool orders is also evident. Coal will soon be running in quantity direct to the piers from producers who desire to load on ships, lighters, etc., outside of pool regulations, thus restoring the competition as to class fuels. Whether the pools will be abandoned completely is a question, for while the majority of larger coal shippers and producers seem to favor some such move there is a considerable element in the trade that favors a continuance of the pooling arrangement under Government control. The Federal Railroad Administration is also said to be favorable to an upkeep of the pooling plan.

Anthracite—The anthracite market lacks any element of snap. The users of fuel who are running low are ordering in one-ton or even half-ton lots, encouraged by the unusually mild winter to believe that an exceptionally early spring may save them from buying in a market which is popularly regarded as top-notch as to price. This sort of buying makes the dealers cautious in orders for the month, and the inducement of independent mine offers of coal at company mined prices is little inducement at all when company mines are closed part days some weeks in order to prevent an over-supply. Even now there is more hard coal here than can be put out promptly, and the yard stocks are slowly mounting despite the effort to hold them down.

Lake Markets

PITTSBURGH

Operation between 25 and 30 per cent. Two sets of market prices. Decreasing consumption.

The coal situation still drags along a weary existence. It is a case of allowing stocks to be liquidated, and the operators seem to be getting along quite well in restricting their operations to the actual demands of the market. Production is between 25 and 30 per cent. of capacity, many mines being closed entirely, while those that operate generally run at between

40 and 60 per cent. capacity. There are two markets, one the regular market for coal to be mined and the other the market for odd lots that through mischance or design have been loaded on cars and must be moved to save demurrage. Such coal frequently goes at less than $2, but the total turnover is small.

The season circular price of $2.50, 15c. over the former Government limit, has not been formally withdrawn, but is a dead letter except as to high-grade gas coal, which occasionally brings up to $2.60 for ¾-in. Byproduct coal and ordinary gas coal generally bring about $2.35, with occasional shading. The general market is quotable roughly at $2.10 for slack, $2.35 for mine-run and $2.50 to $2.60 for ¾-in. gas, per net ton at mine, Pittsburgh district.

Railroad consumption of coal has fallen off, as has consumption by the steel industry, which each week operates at a lower rate than the previous week. The steel mills in the Pittsburgh and valley districts, however, are doing better on an average than mills elsewhere, most of them operating at between 60 and 90 per cent. Many small detached mills are closed entirely. There is almost as heavy coal consumption as formerly by the byproduct coke ovens. It was owing to the indifference of byproduct coke operators that the Geological Survey had to discontinue the weekly report of production, and it is not certain that the proposed monthly reports can be carried on. While stocks of coal held by consumers have been decreasing they are still a factor, and a late opening of lake coal shipments is expected, so that it may be quite a while before there is much improvement in coal demand.

Miners in some sections are reported as being in a restless mood, but in general the miners understood that the operators are curtailing operations for the purpose of maintaining the market and recognize that this is desirable if their wages are to be maintained.

TORONTO

Market remains quiet. Dealers doing business at a loss. Large stocks on hand. Some price-cutting in bituminous.

The demand for coal though far below normal at this season shows a slight improvement, but is mainly confined to the class of small consumers who buy only for present requirements. Dealers who laid in large stocks as soon as the opportunity offered are carrying on business at a loss and claim that the present price of $11.50 for anthracite leaves no margin for profit. Several of the smaller dealers have suspended business. There is no change in the situation as regards the demand for bituminous, which remains limited, but prices are generally well maintained, though in some cases deductions are being made in order to push sales.

BUFFALO

No improvement in coal demand. Bituminous moving slower than ever. Mines shutting down when orders run out. No move to load anthracite into vessels.

Bituminous—The trade slows up perceptibly, for the industries of the country are not yet active. The factories do not know what to do. Everything costs so much that the consumer is buying as little as possible. So long as this state of things lasts the consumption of coal must be light. From all sides still come reports that stocks are heavy and not running down, for the seller somehow manages to get enough coal into consumers' hands to keep the supply up.

At the same time the prices are strong. Less report is heard of cutting than when the Government price was dropped. The fact is that it would take a disastrous reduction now to interest the consumer. He does not call the prices so very high, but he has coal enough and often has no more room for it. How, then, can he buy? So all that can be done is to sell a little here and there. It is likely to last quite a long time, perhaps till the labor deadlock is off. Capital cannot see a return dollar for a dollar spent at present figures, either for material or for work. The effort to keep all prices up may succeed, but it is not much of a success yet.

Meanwhile the bituminous jobbers are uneasy. They have a hard time to make a living and they see nothing better ahead. The question with most of them is whether they can go on in this way till business moves again. Even those who did fairly well awhile ago are now complaining with the rest. They believe their poor sales are due to a falling off in consumption. The only improvement in the situation is that the refusal to reconsign cars will be given up at the end of the month. The rule requiring them to guarantee freight on the shipment of slack into Canada is not regarded as a great hardship. They do not believe it will be strictly enforced, any more than it was previously.

Shutting down the mines is now the rule, just as soon as the coal begins to accumulate. It will not answer to send it out on consignment, for a loss is pretty certain and sometimes it is heavy. The margin, either to the operator or to the jobber, is too small for anything of this sort. Meanwhile the prices are strong.

Anthracite—The announcement that the price is to be allowed to advance 75c. a ton will astonish most of the trade, as only 50c. seems to have been asked. It will do what it can to make this coal a luxury. Maybe that is what the producers are after, for the supply is not everlasting. At the same time the mines that were allowed a margin over the others are down to the general level and finding it hard to sell their output at that.

The demand is everywhere light. Many orders have been cancelled lately, for February is turning out not to be much colder than were the other winter months. The anxiety expressed by distributors some time ago lest there should set in a severe spell of weather lasting some weeks and so create a shortage of coal is now about laid aside. The supply is no doubt sufficient for all emergencies and every day makes any sort of stress less likely. What is now troubling many consumers is how to get rid of the substitute fuel that they have laid in.

Nothing more is said of loading lake coal. The upper lake supply is so large that nobody there wants any early, so the thing is to wait and let the spring take care of itself. If loading a good-sized fleet here right away would take care of the surplus it might be undertaken, but as it would not the best thing to do is to wait. The miscalculations made in the estimates last season have produced a decidedly embarrassing result, but that is now a matter of history. It does not appear to have been avoidable.

CLEVELAND

Both the steam coal and domestic markets continue to mark time. A slight stiffening is noticed, chiefly because of the 25c. increase in Pocahontas at the mines. Receipts in northern Ohio still are about 40 per cent. of normal. The cheaper grades of steam coal can be had all the way from $2.15 to $2.60—the last Government maximum.

Bituminous — Statements, predictions, speculations and hopes that business will be revived are more numerous now than at any time in the past month; but, like all that has gone before, the improvement appears to be confined to the printed page. Industry in northern Ohio continues to operate at about 50 per cent. of capacity. Roughly, about 40 per cent. of this operating percentage is being done by power generated from stock-pile coal. The state of the steam-coal market thus becomes obvious.

Local operators are living in the future and look forward to the opening of navigation on the Great Lakes, which now is only five weeks off. But even this does not fill some No. 8 operators with optimism, for upper lake dock men appear more strong for Pocahontas—now that it is once more obtainable—than ever before—and considerable No. 8 coal will be crowded out of the lake market. In the meantime, operators are keeping mine operations apace with demand, and three days a week is a mighty good schedule for southern and eastern Ohio.

Car shortage is a subject not now discussed; it may be said to exist no longer. Labor at the mines is becoming restive, but is showing no inclination to accept a lower wage in order to stimulate business. In several cases operators have put out feelers among their mine workers, but acceptance of a lower wage apparently is something foreign to the thinking of the workers.

The larger operators are standing pat on the Government maximum, but steam coal can be had in varying tonnages from $2.15 up to $2.60. Some coal has been said to have been tendered at less than $2.15, but the range from $2.15 to $2.60 pretty nearly represents the market. A steam-coal user can buy fuel within those limits according to his luck in happening on to car service coal and what is understood to be second-grade coal.

Pocahontas lump has finally made its appearance in quantity and is retailing at $7.50. Run-of-mine is priced at $7.20. Its competitors are anthracite at $10.85—which is a reduction of 40c.—No. 8 Pittsburgh at $6.35, Massillon lump at $7.10 and West Virginia splint at $7.15. On account of the small demand for slack, Pocahontas operators have added 25c. to the price at the mines. This has served to stiffen the market for all grades, although a slight raise would add strength to the market's present weak state. Domestic demand shows a slight increase as colder weather has set it, but it cannot compare with normal.

Anthracite—The promised reduction of 40c. has been made in domestic anthracite, which is now priced at $10.85. The incoming of Pocahontas has cut slightly into the demand for anthracite.

Lake Trade—The trade continues without word of a reduction in demurrage rates, which is held indispensable to the abandonment of the Great Lakes coal pool. If nothing is done prior to the end of March the pool will be continued in a way, it is said. "Private" pools, such as has been conducted at Huron, Ohio, by three large lake shippers prior to the larger pool, probably will be resumed. In the absence of a new price the last one is holding, but this is still open.

DETROIT

Little buying is being done in bituminous by either the steam or domestic trade.

Bituminous—Orders for bituminous are not coming out freely, jobbers say, notwithstanding some recent predictions that the removal of Federal zone rules and control would impart considerable stimulus to the market. Under more normal conditions such a result might have followed the lifting of Government barriers. The situation in the local market at present, however, may be described as abnormal, made so by the excessive supplies of bituminous in reserve at the steam plants and the storage yards of the retail dealers.

The working down of these supplies is not proceeding rapidly. The factories are using less coal than a few weeks ago. Instead of running at capacity production, the cancellation of Government contracts has left many in a position where operation is limited. The restoration of before-war business is being attempted, but in many instances obstacles are encountered such as delay by the Federal Government's representatives in completing settlement of claims of contractors and the lack of promptness in removing equipment installed by the Government for war work, which is now in the way of the equipment that must be replaced to resume business on products turned out before the war.

Unusually mild temperatures have interfered with the movement of coal from retailers' yards, by curtailing demand from domestic consumers. The retailers who bought large quantities of bituminous, expecting their customers would be largely dependent on that form of coal, owing to restrictions on the use of anthracite and its limited supply, saw part of their prospective market taken when the Fuel Administration regulations were relaxed to permit use of coke by householders to the full limit of their needs, and again when restrictions were lifted from the use of anthracite.

Anthracite — Supplies of anthracite are apparently adequate to meet all present requirements. While shipments are not large, weather conditions have aided in conserving stock. Numerous Detroit retailers are advertising their ability to supply domestic requirements with any form of anthracite and in unrestricted quantity. The plentiful supply of coke that has been available recently has lessened pressure for anthracite.

COLUMBUS

The coal trade in Ohio is quiet. Little change has been noted, as the weather continues warm. There is a slight increase in the steam demand. Prices remain fairly steady

The Ohio coal trade shows little change during the past week. Demand is still limited to small orders and there is no disposition to stock up under present circumstances. The steam business is showing a little more activity in the way of inquiries, although orders are not numerous. Taking it all in all the trade is playing a waiting game, to see what happens before buying fuel. Prices are fairly steady at former levels, although there is considerable cheap coal on the market.

The retail trade is quiet, as is inevitable when the unfavorable weather conditions are taken into consideration. Retailers are loath to buy under present conditions and are content to try to clean up before spring. There is still some demand for Pocahontas and other fancy grades, but the bulk of that business ha been taken

care of. Retail prices are still maintained at the Government levels. The demand is limited, as it is realized that cutting would not stimulate trade to any extent. Rural dealers are probably doing the best business at this time.

Steam business is slightly more active, especially in the way of inquiries. A canvass by salesmen shows that the larger consumers still have large surplus stocks and will not be in the market for some time. This is especially true of the rubber plants and iron and steel mills. General manufacturing on a peace basis is slow in getting started. The railroads are buying a larger tonnage, but not nearly what the war period required. Public service corporations are probably the best customers at this time. There is some cutting of prices on current business in steam circles, but contracts are still maintained. Operators are now figuring on the renewal of many steam contracts that expire around Apr. 1.

Production in all Ohio fields has been rather light. Estimates show that the Hocking Valley mines produced about 25 to 30 per cent. of normal and other fields in the Southern field about the same. Eastern Ohio is credited with about 30 per cent. of normal.

CINCINNATI

General dullness in the market continues, with consumption below contract deliveries and spot demand at zero.

The absence of demand that has characterized the market for some weeks continues unabated, with no indication whatever that any improvement is to be expected in the near future. So far there has been no effort at stimulation by the expedient of sacrificing prices, as it is generally appreciated that the situation is due solely to an absence of need for coal, and that nothing but demoralization would be the result of price-cutting.

In some instances shippers find it difficult to get large consumers to accept deliveries on contracts, although this situation is not giving rise to any great complaint. The principal anxiety in this market is how soon and how extensively it will be possible to revive business in the West and North, as it is realized that this will depend considerably upon the amount of coal carried over.

It is hoped that the convenience with which the winter's supply was stored and the widespread dissatisfaction with cheap fuel delivered not only here, but especially in Western markets, in place of the accustomed high-grade coals, will make it comparatively easy for producers and handlers of first-class coal to make arrangements for the sale of it. The real suffering in the scramble for business, it is naturally felt, will occur among producers of low-grade coal. For the better grades that comprise most of the coal moving through this market there is no real anxiety regarding market conditions later on, when industrial conditions will have improved and the customary spring activity will be in progress.

LOUISVILLE

General market stagnant, with fair demand for better grades of domestic. Steam coal generally draggy. Prices being well maintained. Expected improvement about Apr. 1.

The situation is showing little improvement at the present time, due to continued mild weather, small demand for domestic and a much smaller demand for steam. Domestic can only be produced at high cost due to inability to dispose of screenings and small sizes, with the result that operators are getting a premium of 20c. to 30c. per ton on domestic, and taking a similar reduction on steam.

Mines are continuing on a two- to three-day basis, with only the larger mines making any real effort to run. Low-grade coals are hard to sell at any price, and operators in such fields are having much difficulty in marketing their product.

Western Kentucky operators are making a hard fight before the Interstate Commerce Commission for better freight rates into the Chicago territory and also into the South, present rates making competition almost out of the question.

Although February is almost over and no ice has been encountered in the Ohio River, movement of river coal continues at a standstill, there being only a few small tows coming through. For a time the rail operators of Kentucky were much worried concerning river mines shipping from the West Virginia fields on a lower freight rate, but with the river towns well stocked the river shippers are not making a hard drive for business. Some coal is expected in March, however.

BIRMINGHAM

Steam market very quiet with little spot demand. Domestic mines unable to meet the requirements for this grade of coal. Dull market conditions being met by decreased coal production.

Market conditions as respect steam coal have shown no improvement during the past week, and there is virtually no demand for the output of the commercial mines in the spot market. Consumers seem to have sufficient stocks to meet their requirements for a time and are refraining from entering the market for more coal. There is a fair tonnage of contract coal moving, which enables the larger mines to maintain practically full-time operation with some reduction in daily output, but numbers of the smaller producers are not running steadily. Steam prices are being maintained on the basis of the Government schedule in effect at the close of January.

Lump and nut coal for domestic use is still very much short of requirements, and while there is some little improvement noted in the local supply, due to the absence of cold weather, other sections of this territory have been unable to secure the fuel needed from this district, and temporary relief has been afforded in the Mobile section by shipments from the Illinois field. The inactive steam market has naturally affected the output of domestic sizes, the bulk of which comes from operations which are primarily producers of steam fuel.

Coke

CONNELLSVILLE

Slightly steadier market. Consumptive outlook not promising. Output further reduced.

The spot coke market has steadied somewhat, through the curtailment in production nearly overtaking the curtailment in consumption. There are still some offerings of demurrage coke, but they are not as numerous as a week or two ago, prices obtainable are no better and such coke is often sold at $4.25 or $4.50. For coke that is to be made after receipt of order a much stiffer situation prevails, and as formerly leading operators refuse to shade $5 for furnace coke or $6 for foundry coke. On an attractive inquiry for a month's or a fortnight's supply of furnace coke $5 might possibly be shaded, but this is doubtful. The operators have so much at stake in their regular contracts, which call for a monthly price adjustment according to the market, that they are anxious to sustain the spot market. The market is quotable at $5 for furnace and $6 for foundry coke, prompt or nearby shipment, with occasional offerings of odd lots at cut prices, while on contract coke there is no market at all.

Blast-furnace operations show a slightly decreasing tendency, but on the whole coke consumption is heavier than would have been expected in such a quiet pig-iron market. The furnaces are making scarcely any sales but shipments against old contracts are fair, and the question is how long customers will continue to take shipments. There was a fairly well attended meeting of blast furnacemen in this general district last week, at which the sentiment was developed that pig-iron prices are too high to develop buying, but no means lay open for effecting an orderly reduction and the matter is left for time to adjust, there being an expectation that the steel mills will shortly reduce their steel prices and that may give a cue to the blast furnacemen.

The "Courier" reports production of coke in the Connellsville and Lower Connellsville region in the week ended Feb. 15 at 200,356 tons, a decrease of 25,430 tons. Raw coal shipments are no longer reported.

Buffalo—The trade is quite as dull as coal. All points report such a light demand that prices are slack and declining. The Buffalo price is now down to $5 to $6, oven price, plus $2.60 freight and a few cents war tax for 72-hour foundry and a dollar less for 48-hour furnace and the off grades generally. Fuel and stock grades are moving at consumer's prices, if at all. Much of this class of coke has to be stocked. No move has been made yet in the ore trade for the coming lake season, but it is expected that the trade will go on much as last season. A period of dullness now may not mean much as to the entire season.

Middle Western

GENERAL REVIEW

Conditions cannot be much worse, and next change is expected to show improvement. Sales being made at Government prices. Question whether Illinois and Indiana will hold on to Michigan market.

The mild spring weather is continuing throughout the Middle West, and consequently even less coal is moving than would ordinarily go forward in a normal winter, when manufacturing activities were at a low ebb. The coal operator and the jobber have one consolation, and that is the situation cannot become much worse. If there is any change in conditions at all, it will be a change for the better.

There is some buying on the part of retailers, but in volume these purchases do not amount to enough to be of any great help or any great factor in the present situation. The steam market continues dead. Every now and then, however, some buyer, looking for a bargain, steps into the market and attempts to purchase coal at a reduction from the present prices. Usually this purchasing agent is able to pick up about all the coal he wishes, at the price he is willing to pay, but what he secures is not standard stuff; in fact, he usually finds that the coal offered at a reduction is not such a great bargain after all.

Prices on all well-known first-class coals are remaining firm. The reason for this is that the operators producing the better grade fuels are usually men who have been in the coal industry a long time, and know exactly how much it costs them to produce their product. After what has been taught them during the war, they feel that it is wiser to close their mines rather than sell their fuel at a loss. The parties making the low prices are usually men new at the coal game, and they probably do not know what it costs them to produce their coal. This type of operator just referred to has always been a stumbling block in the path of the entire industry, and will continue so until steps are taken to curtail his activities by those in authority.

Since Feb. 1, the buying public, both steam and domestic, have been divided into two classes. The first—those who want good coal and will pay for it. These men usually have a system whereby they can tell exactly how many heat units they get for a cent, and are fully aware of the folly of buying poor coal when the best offered is to be had at a fair price. The second class—those who may be termed "bargain hunters," consists of men tempted by the price alone, and hypnotized into the belief that they are getting standard coal below what the coal is really worth. It is encouraging to note that although little coal is being bought, most of it is sold at the old Government prices.

The situation in Michigan at this writing is perhaps worthy of note. Before the war, practically all coal going to that state originated east of the Ohio state line. During the war, and until the zones were lifted, Michigan was shut off from Eastern coal, as that fuel either went to the seaboard or was consumed by adjacent war industries. As a result, Michigan had to fall back on Illinois and Indiana mines for its fuel supply, and a large tonnage of mid-West coal was shipped into a market hitherto closed to it. It was a great question, and is still open to debate, as to whether or not the best grades of Illinois and Indiana coals will stick to their new market when normal conditions return.

As it looks now, Michigan has gone back stronger than ever to eastern coals, being willing to pay extra for the higher quality. This is especially true of the retail trade, as practically no Indiana or Illinois coal is moving to retailers in Michigan at this time. So far as steam business is concerned, some Indiana coal is being used and will continue to be used, but only the best grades that Indiana has to offer. Practically no Illinois coal is moving into Michigan, as the freight rates from Illinois mines to points in Michigan are high; in fact, so high that Illinois cannot compete with Indiana in the Michigan market, and therefore what cheap steam coal is being bought for Michigan is obtained from Indiana properties producing good coal and enjoying low rates.

CHICAGO

Practically no market. Retailers with large stocks face big financial loss. No demand for anthracite.

There is little to say about the steam coal market in Chicago, as there practically

is no market. Reports come in from time to time to the effect that plant after plant is either closing down for the time being, or working from one to three days per week. No news about new plants opening or renewing industrial activities.

The rule of the Fuel Administration in Chicago has brought about a curious situation, which will undoubtedly result in a substantial loss to a great many coal dealers, especially some of the largest dealers in this city. When all prices and other restrictions were removed by the Fuel Administration, many of these dealers found their yards stocked with a heavy tonnage of Illinois and Indiana coal—lump, mine run and screenings. Since the market eased up, it has been almost impossible to sell this accumulated storage coal at anything but a big loss; in fact, it is a difficult thing for the dealer to break even on what he has stored. Eventually this is going to work a great hardship on the retail trade in this city, as some big losses will have to be stood.

Coal from the anthracite field, as well as the West Virginia and eastern Kentucky fields, is being offered freely to the trade, with little sold. The idea of the retailer at this time is to clean up his yards and get rid of all the coal he has on hand before he obligates himself for any further fuel.

ST. LOUIS

Warm weather continues and there is no demand for any kind of coal. The surplus of screenings has brought about a critical condition at the mines. Railroad demand light, cars plentiful and transportation good.

The coal situation in this region continues to grow worse, owing to the mild weather. A great problem right now in the Standard field is to move the screenings. Some mines have been accumulating screenings for over four weeks, and all the tracks available are loaded. The railroads have been more lenient with the operators in allowing their idle equipment to stand on the tracks filled with screenings, but it has about gone the limit. Several mines that were loading railroad coal are jammed up with mine-run and are unable to move it.

There is a little demand for lump in the Standard field but it is almost impossible for the mines to work on account of the other sizes not moving. The miners are dissatisfied because they are not getting sufficient work to pay their living expenses.

The Mt. Olive operators are up against it. The Fuel Administration, in its desire to help the situation in St. Louis a year ago, classified the different coals. Several coals were taken out of the Standard field because of their quality and preparation, and put in the Mt. Olive classification. These operators, with a lower producing expense than the operators in the Mt. Olive field, are able to sell their coal for 55c. a ton less than the Mt. Olive operators are getting, with the result that all the Mt. Olive coal coming into St. Louis is the coal that was raised from the Standard grade to the Mt. Olive. This action has shut out of St. Louis almost entirely the real Mt. Olive coal, and the situation is a strenuous one for the Mt. Olive operators. The little coal they are moving from this territory is going north and on some railroad contracts. An effort is being made to have the Fuel Administration show the cause for the classification at the time it was made and that that reason does not exist today.

In the Carterville field of Williamson and Franklin Counties, and also in the Du Quoin field in Perry County, the mines are having a strenuous time to keep working as much as half time. It is a matter of steam coal here, too, there being no place to put screenings as a rule; but even at that the demand for the screened sizes is not anywhere near what the operators anticipated. Screened coal is holding pretty well to the $2.75 price in Franklin County, while in Williamson County the association members are asking $2.75 and the independents are asking as low as $2.35.

The mines in the Big Muddy district around Murphysboro in Jackson County are idle and have been for some time, on account of their inability to move sizes.

In the St. Louis market proper business is at a standstill. There is practically nothing moving in the way of steam, for the storage piles are being used up. The same applies to railroad coal in a general way.

The mild weather brings no demand for domestic tonnage, only in small lots. There is no demand for the anthracite that has been brought in recently, and the little tonnage of Eastern smokeless that is coming in is for the most part being piled up in the dealers' yards. The same applies to the coke situation.

The prevailing prices are, per net ton f.o.b. mines:

	Mt. Olive and Staunton	Standard	
Franklin County:			
Prepared sizes (lump, egg, Nos. 1 and 2 nut)	$2 75	...	...
Williamson County:			
Prepared sizes (lump, egg, nut)	$2 55	$2.55	(As noted
Mine-run	2 20	2 20	above)
Screenings	2 05	2 05	...

Williamson-Franklin rate to St. Louis is $1.10; other rates, 95c.

MILWAUKEE

Fine weather keeps the coal market flat and stale. Prices held firmly. Consumers buying soft coal in preference to anthracite at present prices.

The coal market continues flat and stale, with the weather still in favor of the consumer. As one dealer remarked: "Last year they were chasing us; now we are chasing them." Prices are being maintained, notwithstanding, and the probability is there will be no letting down until present stocks are exhausted. All yards are well supplied and are not in the market for additions to their stocks just at present. If a break ever comes it will be in soft coal, and then only in the event that Western operators begin to shade rates in order to capture new business. Coke is also firmly held, but producers are not disposing of their output with as much rapidity as formerly. Coke and anthracite coal are both deemed too high, and while there is a hue and cry throughout the city about the filthiness of soft coal smoke, dealers say there will be more soft coal burned regularly from now on, especially if coke and anthracite are maintained at anything like present figures.

The state fuel administration office will close for good on Mar. 1, in fact it is practically closed now, there being only a few of the clerical staff at work making out reports of the activities of the office during its existence.

General Statistics

CENTRAL PENNSYLVANIA SHIPMENTS

Traffic reports from the railroads for the week ending Feb. 8 show that the greatest falling off in coal shipments occurred in the central Pennsylvania field. During that week 20,970 cars were shipped from the district, as compared with 25,481 cars the week before, the loss amounting to 4511 cars, or 18 per cent. Market conditions and numerous embargoes against tidewater shipments were responsible.

The second largest loss occurred in the district which embraces southern West Virginia and northeastern Kentucky. Shipments from that territory amounted to 17,273 cars in the week ending Feb. 8 as against 18,498 cars for the week of Feb. 1. This was a loss of 1125 cars, or 7 per cent.

Other districts showed the following totals for the two weeks under consideration:

	Feb. 8 Cars	Feb. 1 Cars
Western Pennsylvania	6,623	6,654
Cumberland-Piedmont-Somerset	4,453	4,478
Fairmont	3,906	4,059
Michigan	451	327
Ohio	12,142	11,382
Southwest Virginia	2,247	2,135
Tennessee and Southeast Kentucky	9,466	9,809
Alabama	3,145	3,174
Illinois, Indiana and Western Kentucky	32,700	30,233

JANUARY ANTHRACITE SHIPMENTS

The shipments of anthracite in January, as reported to the Anthracite Bureau of Information in Philadelphia, amounted to 5,934,241 gross tons, a gain of nearly 200,000 tons over the preceding month and of nearly 300,000 tons over January, 1918. The opening month of last year was one of almost unprecedented severity which, while creating an urgent demand for coal, seriously handicapped its production and transportation. The shipments in January, 1918, amounted to only 5,638,383 gross tons, more than 1,600,000 tons less than were made two months later in March. In December, 1918, the shipments amounted to 5,736,260 gross tons. The exceptionally mild weather of this winter has been favorable to mining and transportation, and as a result production was well maintained up to the last day of the month, the shipments being the heaviest for January, with two exceptions (1913 and 1917) in the history of the trade.

The shipments by companies were as follows:

	January, 1919	January, 1918	Coal Year, 1918–1919	Coal Year, 1917–1918
P. & R. Ry	1,155,803	932,146	12,614,019	12,351,463

COAL AGE

Volume 15 New York, March 6, 1919 Number 10

Lessons Worth Learning

By Floyd W. Parsons

THE war has undoubtedly widened the outlook of all humanity; both labor and capital have gained in imagination. However, it appears now that mankind's social vision has outstripped mankind's ability to make the dreams materialize. Radicals throughout the world are taking advantage of the moment to preach an abandonment of the old order of things and an adoption of an entirely new order—or a lack of order.

It is perhaps fortunate for other nations that in Russia we see the spectacle of what happens under a government that holds forth the belief that wealth can be obtained by the individual without working. In Russia we see the dire consequences of a rule based on prejudice and class hatred. We now know what to expect of a government operating entirely for selfish benefit and having no thought of injury to others.

Bolshevism has revealed itself to an astonished world and is nothing more or less than a "starvation conspiracy." It is an administration of crushed skulls and bayoneted bodies. Not even in the Dark Ages, when humanity was emerging from a state of ignorance, was there a government equally as inhuman and unjust.

Here in America, even though an ocean separates us from the turbulent peoples of Europe, we are not safe in believing ourselves independent of the troubles abroad. The United States harbors many people, especially those of foreign origin, who do not realize that prosperity cannot be organized under a rule by class, whether that class be capitalistic or labor.

There is room in this country for an educational campaign that will teach loyal citizens to meet reason with reason, but at the same time to understand that force can be met only with force. There should be no further parleying with those who create disorders. Sympathy must be extended to the workers and to those who desire to work, for these are the ones who show good faith. Americans must be taught that the solidarity of the whole mass is superior to solidarity of the class. Class patriotism is a menace, while mass patriotism is sound and true.

The chief danger here in the United States lies in the fact that Americans may fail to distinguish between conditions that exist here and those that have existed, and still continue to prevail, in Russia, Germany and other countries. In these countries the people in destroying their governments got such momentum that they want to keep on going and wipe out institutions that are not a menace but part of their very lives. Thus they have attained to the other extreme and have brought about the elevation of labor over capital, which is no more to be desired in its extreme form than the order that existed before.

New ideas are always infectious. So it is not surprising that following the disorders in Russia and elsewhere some of the labor leaders in other countries have announced that what they are really after is not so much short hours and increased pay as a destruction of the whole capitalistic system. This was the talk in Seattle and down in Buenos Aires, where the workmen were enjoying record wages and still were so greedy that they did not hesitate to injure the whole cause of unionism, in order to gain a personal and purely local advantage.

Great danger lies in the present doctrines of foreign origin that are wholly ***unadapted to*** America. It is the duty of every citizen who loves this land of his birth or adoption to see that propaganda of an insidious nature gets no foothold here. It was inevitable that with the coming of unemployment we would get the radical agitators. However, there is no reason, even in these serious times, for our confusing ideas and ideals.

During the war labor and capital were cordial in their attitude one to the other. Now in these less favorable times we must place a firm heel on everything tending to create discord. Capital must bend every effort to maintain wages at the highest possible standard. On the other hand, the workmen must not forget that the cost of earning a dollar can never for any length of time be more than the dollar itself. Above all else, the workingman today must think for himself. In too many cases the rank and file do not oppose extreme views, even when they are clearly unjust. Never has America had such an opportunity to lead the world as it has today. All that is needed is sound sense on the part of individuals and confidence on the part of all classes in their dealings with each other.

Use of Lignite, Bagasse and Wood Waste for Power Generation and Heating

By John B. C. Kershaw
Colwyn Bay, North Wales

SYNOPSIS — *There are immense deposits of lignite in the United States, Canada, Australasia, and other parts of the world, the development and utilization of which are of great interest. The four principal methods of using this fuel are here described in detail; they include air drying and use in the natural state for power generation; briquetting; distillation and gasification. Various plants in this country and in Europe are described. Note is made of the properties of bagasse and the methods of burning it; also the method of using wood and sawmill refuse.*

THE work of the U. S. Geological Survey has revealed the existence of very large areas of lignite in North Dakota, Montana, Wyoming, Colorado and Texas. In the first-named state, it is estimated that the deposits cover 32,000 square miles of territory, and are capable of producing several hundred billion tons of brown coal. According to reliable authority, there are also vast deposits of lignite in Alberta, Saskatchewan and Manitoba, in the Dominion of Canada, and 1700 square miles in Australasia. The total world deposits of this fuel, consequently, are probably equal to those of the other and deeper-lying coal measures.

The developments that are now occurring in the use of lignite are therefore worth studying, in connection with the better utilization of the fuel resources of the world; the following résumé of all recent articles and publications upon the subject, especially of those dealing with American practice, ought to prove of interest and value to readers of *Coal Age*.

Lignite is a fuel intermediate to peat and ordinary bituminous coal as to age and also in respect to chemical properties. The percentage of water in freshly mined lignite is large, ranging from 30 to 50 per cent., and even after air-drying, the moisture content is still quite high, and varies from 10 to 20 per cent. When large lumps of lignite are dried rapidly, the escape of the excessive moisture causes them to break up into small pieces; this crepitation of course detracts from the value of lignite as a fuel, except after briquetting or other treatment. The ash content varies from 5 to 10 per cent. and the volatile hydrocarbons from 35 to 45 per cent.

Four methods of utilizing lignite are in operation in different parts of the world: (1) Air-drying and use in the natural state for power-generation; (2) briquetting; (3) distillation; (4) gasification. The most notable examples of these four different methods of use will now be described.

Power Generation from Air-Dried Lignite — The electro-chemical works at Bitterfeld, in Saxony, are operated entirely with electric power derived from the extensive beds of lignite which occur in the vicinity. In fact, the site of these works was purposely chosen by the promoters because it was believed that the cheapness of the power would more than counterbalance the distance of the works from the usual markets for the manufactured goods. These works are an offshoot from the original German electrolytic soda works, at Griesheim, near Frankfort, operating what is known as the "Elektron" process of soda and bleach manufacture. The fact that these Bitterfeld works have been greatly extended since their erection in 1894, when the plant was designed for the utilization of only 3000 hp., proves that the successful production of electric power from lignite was quite possible, even under the pre-war conditions of competition with power derived from coal and water.

Few details of these interesting works, or of the power plant, have been allowed to appear in print. It

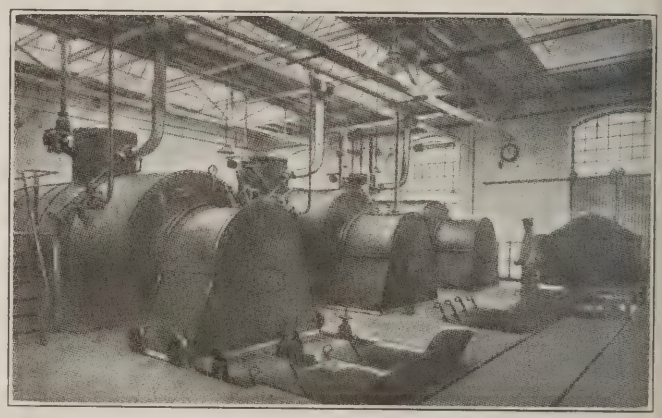

FIG. 1. GENERAL VIEW OF BOILERS FOR BURNING LIGNITE IN GERMANY

is known, however, that the lignite is cut from the beds in which it is found by mechanical cutters or shovels; it is subjected to a certain amount of air-drying, and is then carried to the works by aerial transportation. No official figures showing the actual results obtained at the power plant have been published. A German paper[1], however, in 1908 published an illustrated description and tests of an installation of four tubular boilers with step grates specially designed for operation with lignite; some details of this plant are given here, for no doubt the Bitterfeld power plant is similar in many respects.

Figs. 1 and 2 show a general view of the charging floor of the boilers, and also a sectional elevation of the grate. The latter, it will be seen, is sunk below the floor level, and the lignite is dumped directly into the charging hoppers from the cars in which it is brought into the boiler house. A sliding door, divided into three sections, regulates the admission of the fuel to the grate of each furnace. The angle of the step grate can be altered from the ground level. The lower

[1] "Zeitschrift Vereines Deutscher Ingenieure," Vol. 52, Feb. 15, 1908.

part of the grate is horizontal, and the combustion of the partly consumed fuel is completed here. The ashes are then allowed to fall into inclosed ash boxes by drawing a horizontal damper; from these they are discharged into small cars running on a track below the step grate. The admission of air during the discharge of the ashes is prevented by this system of removal. The whole of the lower part of the step grate is inclosed, and the admission of air to the grate is regulated by the levers, which open or close the doors in front of the space under the furnace. The air required for combustion is drawn through a system of pre-heating stoves and as the use of the step grate causes the gradual evolution of the gaseous matter of the fuel, little or no smoke is produced. A secondary air supply, though provided for, is seldom required.

Trials carried out with this boiler installation have shown efficiencies of between 67 and 69.7 per cent. when using a fuel having the low heating value of 2721 kg.cal. (equal to 4897 B.t.u.). From 2.66 to 3.01 lb. of water were evaporated per pound of fuel; the rate of evaporation varied from 2.1 to 4.1 lb. per sq.ft. of heating surface. The waste gases contained from 16.1 to 17.2 per cent. CO_2, corresponding to an excess of air of only 1.08 per cent. above that theoretically required. The successful exploitation of the lignite deposits at Bitterfeld has caused this previously unknown and unimportant place to become a flourishing center of German electro-chemical and electro-metallurgical industries; the rapid developments here prove that electricity, generated by power from burning lignite under steam boilers, is quite capable of competing with electricity produced from the power obtained in the more customary manner. Passing on to consider American practice and experience, Bulletin 89 of the U. S. Bureau of Mines, upon "Economic Methods of Utilizing Western Lignites," by E. J. Babcock, contains some useful information upon the correct methods of burning lignite for power generation. The author of this bulletin states:

The proper combustion of lignite depends largely upon using a size of coal that will give an abundant air surface, but in addition a good draft should be so arranged that the air can be directed through the burning coal to the best advantage, and can also be controlled and closely shut down when it is desired to hold the coal at a relatively low heat. The firebox should be kept reasonably well filled, but the firing should be carried out frequently by the application of thin layers of fuel to the surface of the bed of hot lignite. The ash and clinker should be removed carefully and at a sufficient rate to prevent the accumulation of clinkers.

Many firemen fail to get good results in the use of lignite because of uneven firing. The fire is allowed to run low and then a large quantity of the lignite, much of it in large lumps and carrying a high percentage of moisture, is introduced. The large addition immediately slackens the fire and materially reduces the temperature in the firebox, and by the formation of considerable vapor, reduces still further the temperature of the gases, the heat from which should be left for boiler absorption. By such firing it is impossible to keep a uniform load with a high boiler efficiency, and much loss of fuel is experienced. By using coal of reasonably small size and firing in thin layers frequently, this difficulty is reduced to a minimum.

This view of the conditions required for the proper combustion of lignite is supported by the experience of the Hughes Electric Co., of Bismarck, N. D., which has been using the deposits of this fuel in Dakota for some years as a boiler fuel. According to C. L. Larsen, the chief engineer of this company, in order to obtain a high efficiency with lignite, it is necessary to maintain a high temperature in the boiler furnace, and the proportion of excess air must therefore be cut down to the lowest possible point. Larsen recommends for burning lignite "a flat sawdust grate with ½-in. round holes.

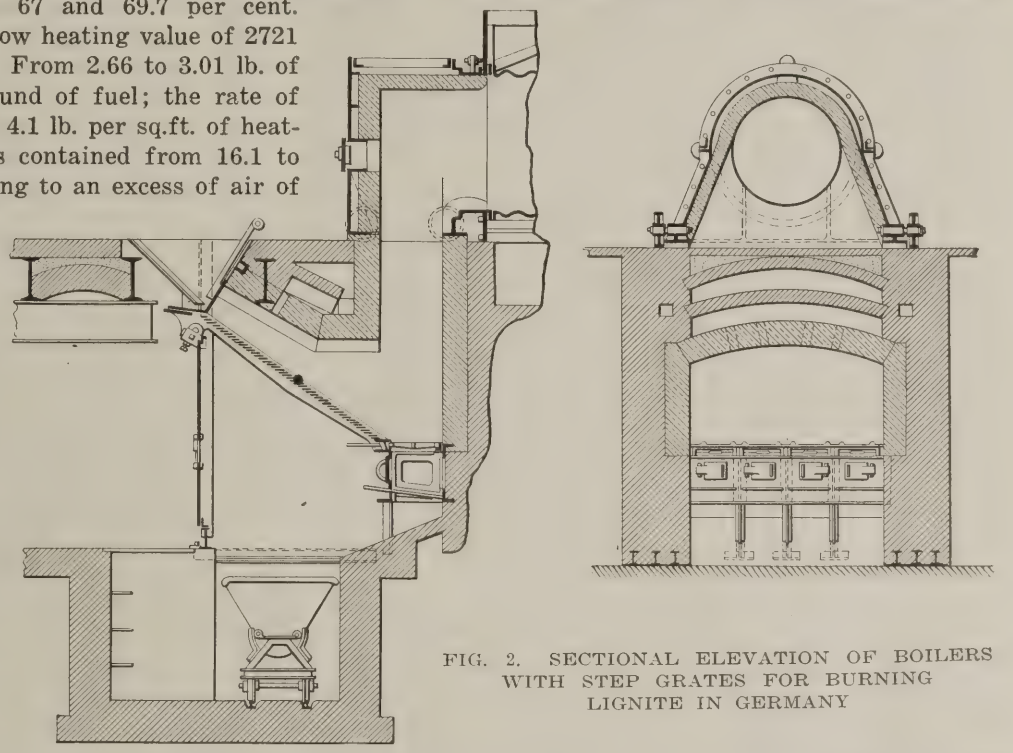

FIG. 2. SECTIONAL ELEVATION OF BOILERS WITH STEP GRATES FOR BURNING LIGNITE IN GERMANY

Such grates contain only 15 per cent. air space, but by having small openings a higher air pressure in the ash pit can be maintained, and the air passes through the small holes and through the bed of fuel at a greater velocity. This produces a high temperature in the furnace, and as the volume is small, the heat is not rushed through the boiler and up the smokestack, but is absorbed by the water in the boiler, and a low temperature in the smokestack is obtained."

Working under these conditions, Larsen asserts that an evaporation of nearly 5 lb. of water per pound of fuel can be obtained from a lignite testing 35 per cent. moisture and 6 per cent. ash, and showing only 7000 B.t.u. in the calorimeter. To obtain such an evaporation result, however, the boiler must not be pushed at all above its rated capacity, and only 3 lb. of water can be evaporated per square foot of surface per hour.

Another American contribution to the subject of lignite is that of Randall and Kreisinger (Bulletin 2 of the Bureau of Mines) upon "The Use of North Dakota Lignites for Power-Plant Boilers." The conclusions arrived at by these two investigators were (1) that a

large combustion chamber was necessary in order to obtain the best results and (2) that the gases yielded by the lignites must be completely burned in this chamber and raised to the highest possible temperature, before being allowed to come into contact with any of the water-cooled surfaces of the boiler. A Dutch-oven type of furnace was employed in this investigation, and the following is their description of the furnace and its method of operation:

The most striking features in the construction of the furnace are the deep-set grate and the contraction of the space between the bridge wall and the end of the prolonged firebrick arch. The furnace is designed to work on the gas-producer principle. The solid fuel is gasified on the grate, and the gas passes through the space under the arch into the combustion chamber, where most of the gaseous combustible burns. The necessary air for combustion is added through the openings in the bridge wall. This air is preheated from 200 to 300 deg. F. in coils, and forced into the furnace under a pressure of from half an inch to an inch of water. The grate is 21 in. below the lower edge of the firing door. The object of this construction is to enable the fireman to carry a thick fuel bed and still see its condition at the top; the side furnace door used in removing clinkers is only seven inches above the grate.

The grate was equipped with rocking bars to facilitate the removal of ash, and each grate bar was supported by a 2-in. pipe through which cold air was circulated. The thermal efficiency of this type of furnace, when used for steam raising with lignite, was from 55 to 58 per cent., and the two investigators state that no difficulty was experienced in working up to the full capacity of the boilers. North Dakota lignite has in fact been employed with this type of furnace at the pumping plant of the U. S. Reclamation Service at Willaston, N. D., with good results. Figs. 3 and 4 show sectional elevations of the boiler and furnace.

Lignite Converted Into Briquets

Briquetting—The chief center of the manufacture of lignite briquets in Germany is at Horren, a small town lying west of Cologne, the industry at this place having been developed within the last 25 years. According to C. A. Davis, who prepared a report upon the subject in 1913 for the U. S. Bureau of Mines, there are 26 factories producing lignite briquets in this neighborhood; about 20,000 metric tons were being manufactured daily during the season of active production, at that time. The mines are on the high terraces of a broad shallow valley, the strata of coal are from 230 to 400 ft. in thickness, and the lignite is brought to the various works by an overhead transportation system.

This one district, in 1911, produced rather more than one-fourth of the total German output of lignite briquets, the largest works having 28 presses and turning out about 1600 metric tons of briquets per day of 24 hours. The following description of the method of manufacture and of the plant at the most recently erected works is taken from the report referred to above. The brown coal as mined contains 60 per cent. moisture, and when dried is dark brown in color and easily powdered. The coal on delivery at the briquet factory of the "Gewerkschaft Kohlenquelle" is first crushed and screened, and is then dried in four Schultz driers, each with a capacity of 70 metric tons per 24 hours. Each drier consists of a large cylinder of boiler iron 23 ft. in length and 10 ft. in diameter, mounted on trunnions, with the main axis inclined about seven degrees from the horizontal. Inside of the outer drum or shell of the drier is a second drum fitted with 366 tubes, each about four inches in diameter; the drier thus resembling a modern water-tube boiler. The exhaust steam from the engines is admitted to the space around the tubes, under a pressure of three atmospheres, through valves in the trunnions that support the drier. The moist powdered material is fed constantly from the storage pockets into the tubes by means of spiral conveyors, and the rate at which it passes through the drier is regulated according to its moisture content.

Technique of the Briquet Industry

To reduce 60 per cent. moisture down to 15 per cent. requires the fuel to be three-quarters of an hour in passing through the dryer. The steam from the drier is forced through a cyclone chamber by means of fans, before being turned into the atmosphere through the escape flues. By this plan the dust, amounting to 3 per cent. of the total material dried, is collected from the escaping steam and is added to the material to be briquetted. The air in all parts of the factory building is practically free from floating dust, because the dried brown coal is handled in closed conveyors and dust is not at any point permitted to escape into the factory. In this way all danger of dust explosions, which in early types of such plants were not infrequent, has been eliminated. The cost of the whole process of drying is about 70 pfennigs (or 17c.) per ton of product.

The briquetting portion of the plant consists of five compound three-cylinder horizontal engines, directly connected with open-mold plunger presses. The cross-section of the plunger and mold of this type of press is lozenge-shaped, and in the single presses is about 7 in. long by 2¼ in. wide. In this press the long axis of the mold is horizontal. In the double presses the molds are placed side by side, so that the two briquets formed at each stroke of the plungers issue from the press end to end. The powdered brown coal, containing about 15 per cent. moisture, is fed into the mold from hoppers and is subjected to a pressure of from 18,000 to 22,500 lb. per sq.in. A pressure equivalent to 300,000 to 400,000 lb. is exerted therefore on each briquet. The press forms, or plates that form the molds of the briquet presses, are made of hardened steel and are changed when they become so worn that the plunger no longer fits the mold well enough to make good briquets. The chief cause of the wear is the sand or other mineral matter contained in the powdered raw material. The time that these plates last varies from three days to about four weeks, according to the amount of mineral matter present. The briquets weigh about 7 lb. each. No pitch or binding material of any sort is used in manufacturing them; the tarry matter liberated from the brown coal by the heat developed in compressing the material serves this purpose. The briquet presses are jacketed and water-cooled. Each single press has a capacity of about 70 metric tons of briquets per 24 hours and requires 120 hp.; a double press requires 200 hp.

The power for driving the plant is obtained from a battery of eight boilers, fired entirely by brown coal as

mined, and containing 60 per cent. moisture. The boilers together furnish 750 hp. and supply steam to the engines at a pressure of 180 lb. In addition to the boilers there is a superheater in which the steam for the driers is superheated to 300 deg. C. One carload out of three of the brown coal brought to the plant from the mine is sent directly to the feed hoppers of the boilers. From these hoppers the material is fed by mechanical stokers to the fires, and is burned on step grates. Each boiler has about 1300 sq.ft. of heating surface; 270 sq.ft. of superheater area and 65 sq.ft. of grate area. Only three men are required to attend to the entire battery of eight boilers—one keeps the feed hoppers filled, shifts and empties cars, etc.; the others attend to the stokers and grates. The briquets sell for $1.90 per ton at the factory; the retail selling price at Cologne in 1913 was $2.75 per metric ton.

As regards American experience, the U. S. Bureau of Mines in 1908 to 1910 carried out some valuable experimental work with the lignite found in North Dakota, Texas and California, in order to ascertain whether the methods and form of briquetting press used in Germany (and described above) could be applied with success to these American lignites.

[2]"Briquetting Tests of Lignite at Pittsburgh, Penn.," by C. L. Wright.

The results of this inquiry are recorded in Bulletin 14 of the Bureau of Mines[2], and although the investigation was not completed, sufficient testing has been carried out to prove that many of the American lignites are quite as good as the German ones in thermal value, and that they can be briquetted upon a commercial scale without the use of any binding material. It has also been proved that contrary to the generally held opinion, lignites that had been slacked by exposure to atmospheric influences could still be briquetted without a binder. Cohesion and weather tests which were made with raw lignite, and with the finished briquets, showed that the latter were the superior in resistance to handling, and also to weather influences.

With regard to practical developments, a description of a plant at Denver, Colo., designed for the commercial production of briquets and valuable byproducts from lignite, was published in *Coal Age*, Apr. 15, 1916. The fuel at this plant is subjected first to dry distillation in order to obtain gaseous fuel, light oils, ammonium sulphate and creosote and pitch; the residue of coke left in the retorts is finally briquetted with the aid of binding materials. The ovens or retorts are designed to take ten-ton charges, and the heating period lasts two hours at a temperature of 500 deg. C. The yield of byproducts at this temperature, per ton of raw lignite, is stated to be as follows: Gas, 10,000 cu.ft., tar-oil, 13 gal., ammonium sulphate, 2.5 lb. The pitch and some other binding material are employed for briquetting the residue of coke left in the retorts, after the distillation is completed. The briquets, or "carbonets," as they are called locally, have the following composition: Moisture, 1.34 per cent.; volatile matter, 7.60 per cent.; ash, 7.02 per cent.; fixed carbon, 84.04 per cent.; calorific value, 14.061 B.t.u. They withstand unfavorable weather conditions and rough handling quite

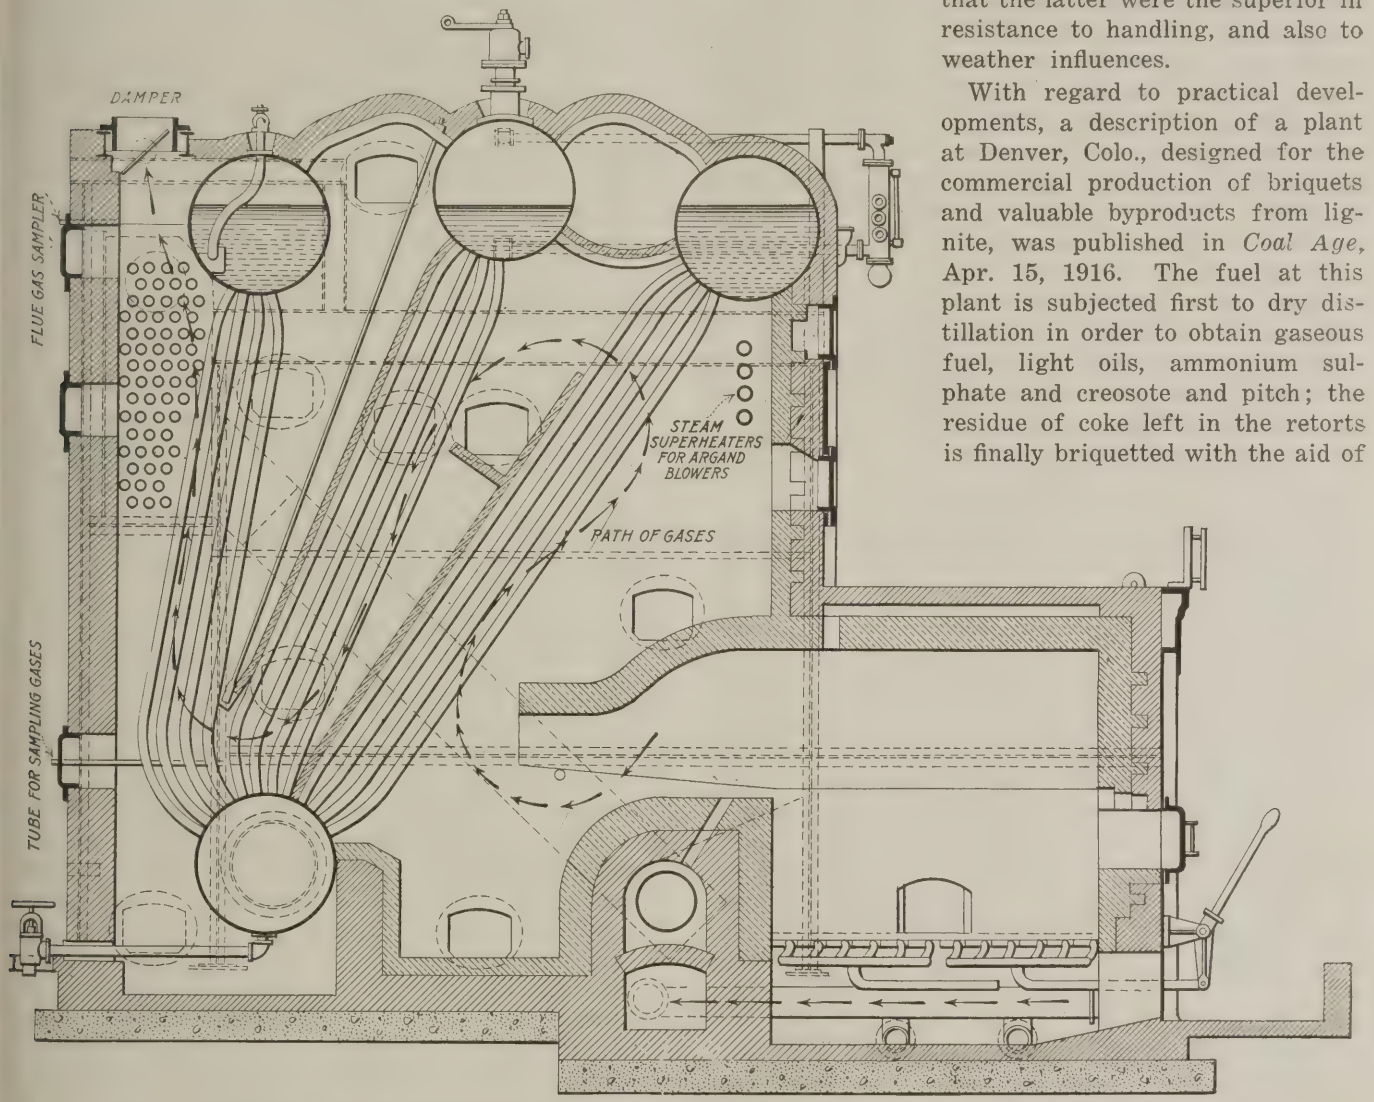

FIG. 3. SIDE SECTIONAL ELEVATION OF BOILERS FOR BURNING LIGNITE AT WILLASTON, N. D.

satisfactorily, and also retain their form when burned until they are practically all consumed. The Denver works as originally planned were designed for the treatment of 500 tons of raw lignite per day, and the briquetting plant for an output of 25 tons per hour.

The details of this method of treating the Colorado lignites were worked out in the laboratory before the works were designed or erected, and it is hoped that this careful preliminary study of all the scientific data will lead to the foundation of a new and flourishing local industry.

Valuable Byproducts Derived from Lignite

Distillation and Recovery of Byproducts—A lignite suitable for low temperature distillation is characterized by a high content of bituminous matter. In the absence of this bitumen the fuel is not adapted for the retort process and is only suitable for direct burning by either of the two methods previously described in this article. One can distinguish roughly between the two classes of lignite by observing closely the changes that occur on heating, and by comparing the specific gravities of the samples. Lignites suitable for subjection to the distillation or retort process melt or soften before ignition and burn with a smoky flame; they also possess a specific gravity between 0.90 and 1.10, whereas the lignites suitable for direct burning do not soften or melt on heating, and have a specific gravity of 1.2 to 1.4.

The distillation of lignite is carried on in Germany at two centers—at Halle in Saxony and at Messel near Darmstadt. Stewart, in a paper read before the Edinburgh section of the Society of Chemical Industry in January, 1917[3], has given a full account of the process as carried out at these two centers, and has described the method and apparatus used for the recovery of the byproducts. The latter consist of crude oil, containing various hydrocarbons of the paraffin and aromatic series, paraffin wax, and a coke testing about 12,600 B.t.u. The yield of crude oil at Halle is about 18 gal. per ton of lignite; in this district there are twelve works which distill one million tons of brown coal per annum and produce 60,000 tons of crude oil and 7000 tons of paraffin wax. At Messel the crude oil is distilled from the lignite in the presence of steam, and the coke that remains in the retorts is dropped directly into gas producers below. Vertical retorts (covered by German patent 200,602 of May, 1906) are employed—the working of these being continuous—and the brown coal is fed into the retort from a hopper closed by a valve. In the upper part of the retort the lignite is dried, and the steam produced here is drawn off by an electrically driven fan. Part of this steam is reintroduced into the retort lower down, in order to keep the temperature at the required low limit; the remainder is used for the gas producer, which is worked with the coke residue from the retort process. The laboratory distillation of the lignite used at Messel yields 44 per cent. moisture; 7.8 per cent. crude oil; 6.2 per cent. gas; and 36 per cent. of coke; the latter, as already explained, is used for gas production and no marketable coke is produced. The actual yield of crude oil is about 19 gal. per ton of lignite; the final products obtained by distillation of the crude oils are benzine, solar oil, pale vaseline oil, fat oil, solar scale, red oil, heavy vaseline oil and paraffin wax.

In America the only distillation works of which full details have been published are those referred to in this article as established at Denver, Colo., in 1915, for the production of briquets and byproducts from the Colorado lignites. The ovens or retorts here are 36 ft. long by 9 ft. high by 18 in. wide; the charging period is 2½ hours, and the temperature limit is 500 deg. C. The average yield is 10,000 cu.ft. of gas, 13 gal. of tar oils and 2½ lb. of ammonium sulphate. The gas is used for heating the ovens and also for steam generation, in order to supply the plant with the necessary electric power; the crude oil is distilled and is separated into light oils, heavy oils and pitch. At temperatures up to 150 deg. C., 10 to 14 per cent. of the crude oil passes over to the light oils storage tank, and between 150 and 325 deg. C. the heavy creosote oils, which form about 68 per cent. of the total oil, are distilled. The manufacture of briquets from the lignite coke has already been referred to under "Briquetting," and it is only necessary to add that the works was planned by C. O. Hoover, of Denver, and that it is owned by the American Coal Refining Company.

A large amount of experimental work upon the distillation of North Dakota lignites has been carried out at Grand Forks by the College of Mining and Engineering of North Dakota, where a specially designed briquetting and gas-making plant has been erected for the purpose of studying the utilization of lignites. The details and results of the investigation are given in Bulletin 89 of the U. S. Bureau of Mines[4].

This bulletin contains a full account of all the experimental work carried out, in order to determine the best conditions for the gasification of lignite. The relation between the moisture content of the raw lignite and the yield and thermal value of the evolved gas was closely studied, and the effects of temperature variations were also examined and tabulated. The statement in Table I, prepared from the figures presented in the bulletin, shows the average results of the gasification tests made in this experimental plant with 25 representative samples of United States lignites.

Certain Lignites Converted Into Gas

Gasification Without Recovery of Byproducts—The fact that many lignites are too poor in their content of bituminous matter to render distillation profitable accounts for some of the past failures that have occurred with plants erected for this purpose. Lignites of this type, however, are quite suitable for gasification without attempting the recovery of the tar or ammonia; there are many places where gas producers, of the type designed for use with bituminous fuel, would prove of great value in connection with the utilization of lignite deposits. Small plants of this kind are quite as efficient as large ones, for there is no necessity to design the plant on the large scale that is required for successful byproduct recovery. Whether the gas obtained from these lignite gasification plants would be best used to raise steam or for direct power production in gas engines would depend upon local conditions and require-

[3]Journal Society Chemical Industry, Feb. 28, 1917.

[4]Economic Methods of Utilizing Western Lignites, by E. J. Babcock.

ments. In New Zealand the use of lignite producer gas for power production is quite common in the electric power stations, and the natural moisture content of the raw lignite renders it possible to work the producers without steam. Producers of this type, in which the upper part is used as a gas retort and the lower part as an ordinary producer, have been designed by Ziegler, Zwingenberger and others and have been successfully employed for peat and lignite gasification in Germany and Austria.

"Bagasse" is the technical name for the tough fiber that is left after milling sugar cane, for extraction of the sugar. The proportion of combustible matter in this residue varies considerably in different districts, ranging from 35 to 60 per cent., while the water content and ash make up the balance of 40 to 65 per cent. In Louisiana the average composition is fiber, 40 per cent., sucrose and other sugars, 7 per cent., and moisture, 53 per cent. The heat value of dry bagasse is found by experiment to be 8300 B.t.u. The proportion of the total heat which can be rendered available in practice, for power generation, depends upon the percentage of water which remains in the bagasse when burned.

Heating Value of Bagasse

According to Freeland,[5] the average Louisiana product has a calorific value of about 8300 B.t.u. per lb. of dry bagasse, and from 3620 gross (56.7 per cent. moisture) to 4800 B.t.u. (42.8 per cent. moisture). The net heating values are respectively 2200 and 3350 B.t.u., and 1 lb. of this wet bagasse will evaporate from 2 to 3½ lb. of water, from and at 212 deg. F. Professor Kerr found that at a Louisiana sugar house the bagasse from one ton of cane generated from 1.16 to 1.44 b.-hp. The bagasse from a 1000-ton house will generate therefore a total of 1160 to 1440 b.-hp.-hr. per 24 hours, and it would require about 60 tons of coal per day to do the same work. Professor Kerr has also stated that in Louisiana 16 per cent. of the total heat generated by the combustion of 1 lb. of bagasse was required to evaporate the moisture present in the raw material. As about 14½ per cent. of the moisture in bagasse could be removed by drying, the dry bagasse had a heating value 55 per cent. greater than the wet bagasse. For this reason the methods of burning bagasse are now being improved, and in the larger sugar-cane factories of Cuba and Hawaii the bagasse is subjected to a preliminary drying before entering the combustion area of the grate.

TABLE I. AVERAGE RESULTS OF GASIFICATION TESTS

	Yield per Ton	Calorific Value per Cu.Ft. B.t.u.	Composition—Per Cent. H	CO	CH_4	CO_2	N
Gas	11,038 Cu.Ft.	396	40.1	20.09	15.31	10.48	9.98

	Yield per Ton, Lb.	Calorific Value B.t.u.	Composition—Per Cent.—Vol. Matter	Ash	S	H_2O
Coke	1,092	11,838	C 75.52	7.57	15.91	1.98	1.00

Methods of Burning Bagasse—The grate surface must be small in furnaces intended for burning the waste sugar cane, since the rate of combustion is high, rising at times to 300 lb. per square foot of grate surface per hour. In some of the recently installed 500-hp. boilers the grate area is only 25 sq.ft., whereas a coal-fired boiler would require quite three times this area for the satisfactory combustion of the same equivalent weight of fuel.

In many other respects, the grates and methods used for burning bagasse resemble those employed for coal, with high volatile matter content. Mechanical stokers are also now being tried since, with stokers of the coking type, the bagasse can be subjected to a preliminary drying and its heat value improved before actual combustion occurs. When used with these stokers the bagasse is spread out upon the front portion of the stoker and the rate of feed is regulated so as to obtain the maximum heating effect. Furnaces of the step-grate type are also being used in some of the more up-to-date sugar mills, for the air supply is more easily controlled with this type of grate.

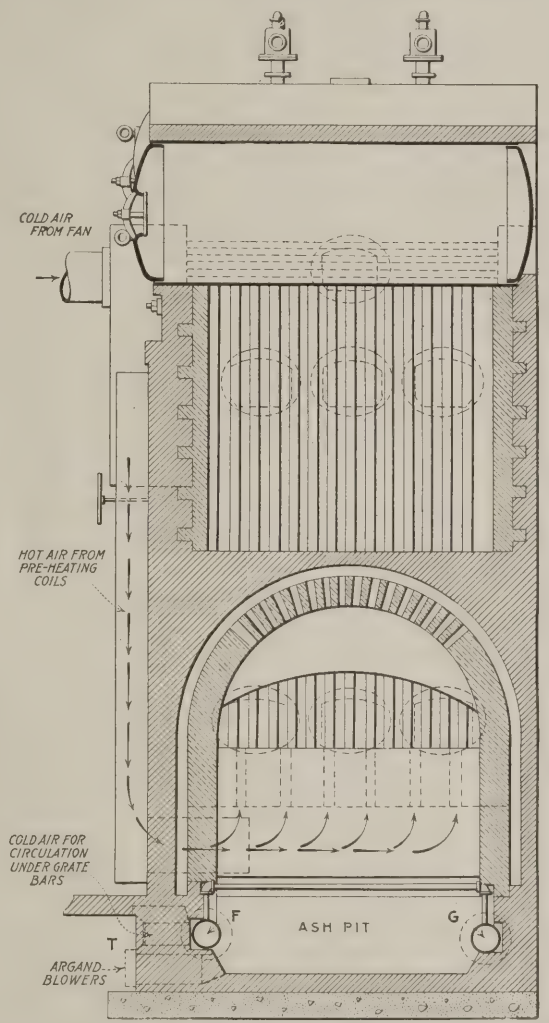

FIG. 4. END SECTIONAL ELEVATION OF LIGNITE BOILERS AT WILLASTON, N. D.

Sawmill refuse is one of the staple fuels for steam-power plants in certain of the timber-felling districts of the United States, Canada and Australia, and a considerable amount of power is also developed from the wood shavings and refuse produced by the woodworking factories in cities where boxes and packing cases are made by machinery on a large scale. The waste material produced in these mills and factories may be burned either directly under steam boilers, or it may

[5] Journal American Society Mechanical Engineers, November, 1917.

be gasified[6] in producers and the gas employed in gas engines.

According to Fernald, manufacturers of gas producers are now designing producers specially for gasifying the waste fuels of this type; with reasonably dry raw material for feeding the producers, the consumption of wood has been reduced to 2 lb. per b.-hp.-hr. as generated by the gas engine. The figures for the best results yet attained with these various kinds of wood waste, when gasified in producers and the gas used in gas engines, running at full load, are as follows:

	Lb. per Hp.-Hr.
Box blocks	2.15
Mulga scrub	2.30
Pine shavings and blocks	2.31
Jarrah-wood sawdust and shavings	2.40
Spent tanbark (dry)	3.13
Spent tanbark (wet)	4.50
Sawdust	3.50

As examples of the type of furnace used in the United States and Canada for burning sawmill refuse under steam boilers, the equipment at the plant of the Portland (Oregon) General Electric Co., and at the Rockwell Manufacturing Co., New York, may be cited. The boilers at the former plant are provided with external furnaces of the Dutch-oven type. These furnaces are provided with charging holes, into which the sawdust and wood waste are tipped from the conveyors which transport it from the timber yards of the locality, and the Dutch-ovens are kept completely filled in order to prevent air leakage. The two generating stations of the company in Portland, equipped with this style of wood-burning plant, consume 100 to 150 box loads of refuse (equivalent to 20,625 cu.ft.) per day of 24 hours, and the average evaporation attained is 10,500 lb. water, per 200 cu.ft. of cut fuel. Assume that 1 cu.ft. of the refuse weighs 15 lb.; this equals an evaporation of 3.5 lb. of water per pound of wood, which is quite a good result under the circumstances. The calorific value of wood varies from 8300 to 9000 B.t.u., and its maximum evaporation value in practice is 5 lb. of water per pound of fuel.

At the Rockwell Manufacturing Co.'s plant there are two 125-hp. horizontal tubular boilers installed, each 66 in. by 18 ft., with 1250 sq.ft. of heating surface and working at 150 lb. steam pressure. A blower fan system of collection for the woodworking waste is used, in order to collect and transport it to the boiler room. From the storage place on the boiler-room roof the waste fuel falls by gravity into the chutes that carry it to the furnaces.

Six Out of Ten Miners Foreign-Born

In the bituminous-coal industry 62 per cent. of the workers are of foreign birth. The percentages in various other industries range from 85 per cent. in sugar refining down to 13 per cent. in collar, cuff and shirt manufacturing. Three out of four of the foreign-born workers are able to read or write their own language. A little over one-half of the foreign-born workers from non-English-speaking countries are more or less able to use the English language.

[6]U. S. Bureau of Mines, Technical Paper No. 123, "Notes on the Use of Low-Grade Fuel in Europe."

Discrimination in Favor of Shipper Need Not Affect Rates

That there may be a discrimination or concession in favor of a shipper in violation of the Elkins Act as amended by the Hepburn Act, although there is no discrimination affecting transportation charges or rates, is the principal holding in the case of United States vs. Metropolitan Lumber Co., recently decided by the United States District Court for the District of New Jersey.

The indictment charged that the defendants, notwithstanding a governmental embargo on the shipment of lumber, caused lumber to be consigned to the defendants in such a manner that the Pennsylvania R.R. was led to believe that the shipment constituted a consignment of war supplies when in fact it did not, and that thereby a discrimination was practiced. On demurrer to the indictment it was contended that the facts alleged charged no offense in that there had been no discrimination as to rates. The court held this position to be untenable, and decided that a discrimination within the law was charged. The effect of this holding appears to be that any privilege or concession obtained by a shipper, not accorded to shippers in general, is within the statute.

It is also held in this case that a consignee who obtains a discrimination for his benefit is liable as a "shipper" within the law, and that an offense may be committed under the statute although there is no knowledge or connivance on the part of the carrier. The opinion, which is per Haight, J., contains a searching review of the legislation and decisions.

Output of Fuel Briquets in 1918 Greatest Yet Recorded

The production of fuel briquets in the United States in 1918 was 477,235 net tons, valued at $3,212,793, an increase, compared with 1917, of 70,379 tons, or 17 per cent., in quantity, and of $978,905, or 44 per cent., in value. The production in 1918, which represented the results of the third successive year of material progress in the industry, was the highest yet recorded. It was more than double the production in the year 1915.

The number of plants in operation in 1918 was one less than in 1917. Three of the plants that were operated in 1917 were idle in 1918—those of the Denver Coal Byproducts Co. (formerly the American Coal Reduction and Byproducts Co.), in Colorado; the Johnson Fuel Co., in North Dakota, and the American Briquet Co., in Pennsylvania. Two new companies, at Trenton, N. J., began operations in 1918, the Fuel Briquet Co. and the Trent Brick Co. The Belgian Coal Briquette Co., of New York City, and the Anthracite Briquet Co., of Sunbury, Penn., expect to begin operations during 1919.

Of the 12 plants in operation in 1918 six used anthracite as a raw material, one Arkansas semi-anthracite, one semi-bituminous slack, one anthracite culm and bituminous slack, one bituminous slack and sub-bituminous coal, and two oil-gas residue. Coal-tar pitch and asphaltic pitch were used as binders by six plants, one used sulphite pitch, two used no binder, and three used a vegetable binder or employed special processes.

Cost of Mule and Locomotive Haulage

By William L. Cross, Jr.
Scranton, Penn.

FOR some time I have been looking for a method of comparing the relative costs of mule and locomotive transportation with especial reference to gathering and short haul work where frequently it is a question as to which of several systems is the cheaper. This article deals with a method that I finally devised, one that has proved satisfactory.

By means of curves similar to those shown in Fig. 2 most of the problems commonly met with can be quickly and easily worked out on a comparative basis. Other

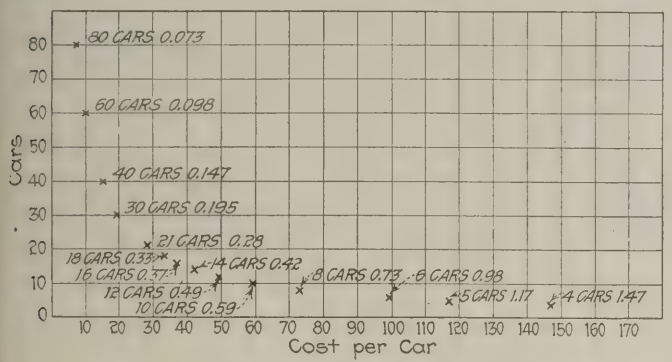

FIG. 1. DATA PLOTTED FOR COST CURVE

factors, such as availability of power and the possibility of securing locomotives and equipment, are matters for consideration after or before the relative costs of the different organizations are determined. The data from which the costs were compiled are not by any means correct for all cases, but a set of curves can easily and quickly be made up for each colliery or group of mines which will be approximately correct in all cases.

The curves are made up as shown in Fig. 1, and from figures similar to those appearing in Table I, worked out in this case for one driver and one mule, as follows:

TABLE I. COST PER CAR FOR ONE DRIVER AND ONE MULE

Cars	Cost per Car	Cars	Cost per Car
4	$1.47	18	$0.33
5	1.17	21	.28
6	.98	30	.195
8	.73	40	.147
12	.49	60	.098
14	.42	80	.073
16	.37		

The figures in Table I, when plotted as shown in Fig. 1, give the basis for the regular curve for an organization or transportation unit of one driver and one mule, The other curves shown in Fig. 2 are plotted in a like manner. In the case of locomotive haulage, the power, installation and repair costs given or estimated for any single locality will not be correct for every installation. This is one weak point in the tabulation. However, because unforeseen conditions usually develop in mine electric installations, and at the present time repairs and repair parts are costly, it is best to be on the safe side and figure locomotive maintenance high.

A close inspection of these curves will also show that the handling of four or five more cars makes much more difference in the cost per car than does a few cents in the figures representing power, repairs, etc. For instance, in the case of a crab locomotive with one engineer and two brakemen working in pitching rooms, let us estimate that this machine will handle 40 cars per day. This, from Fig. 2, would cost 60c. per car. If another place can be added so that the machine will handle 44 cars, it will do so at a cost of 56c. per car—a saving of four cents per car, or $1.76 per day. We cannot always estimate mine haulage possibilities closer than four cars, but our cost figures certainly will not be in error to the amount of $1.76.

Two representative problems are given below to ilustrate the use of the curves:

Problem 1—Assumption by colliery superintendent that his transportation gathering cost shall not be over 60c. per car. How many cars must each unit handle in order to give him this cost?

Follow the dash line on Fig. 2: It crosses one driver and one mule at 10 cars; one driver and two mules at 12 cars; one driver, one runner and two mules at 19 cars; one driver, one runner and three mules at 22 cars; one driver, two runners and three mules at 29 cars; one locomotive, one engineer and one brakeman at 34 cars; one locomotive, one engineer and two brakemen at 40 cars.

Problem 2—It is known that one driver, two runners and three mules in a certain section where there are

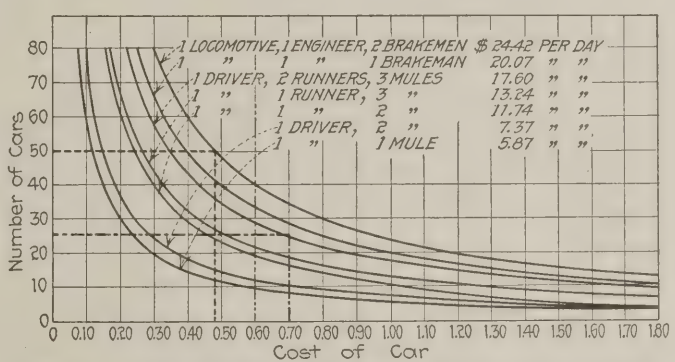

FIG. 2. COST CURVES FOR VARIOUS HAULAGE UNITS

	Per Day
Locomotive Data:	
Power, $90 per month	$3.60
Installation, $2000, 5 per cent of $2000 Depreciation—Locomotive, 15 per cent of $8000 Repairs—Locomotive lines, etc., $900 per year } $2200 pr. yr.	7.33
Labor—Engineer at $0.28, plus $0.25 allowance for 9 hours.	4.77
Brakeman at $0.2351, plus $0.25 allowance for 9 hours	4.36
Mule Data:	
Mule value, $250; 20 per cent. depreciation; 5 per cent. interest	0.23
Feed and care	1.25
Labor—Driver at $0.2351, plus $0.25 allowance.	
Runner at $0.2351, plus $0.25 allowance.	

pitching rooms will handle 25 cars per day. This section due to its development can produce 50 cars per day with two-mule organizations. Which relatively is the cheaper plan, to use two-mule organizations or one crab locomotive to handle 50 cars?

By following the two dotted lines in Fig. 2 it will be seen that one driver, two runners and three mules will handle 25 cars at a cost of 70c. per car; one locomotive, one engineer and two brakemen will handle 50 cars at a cost of 48c. per car. This shows in this case, of course, that the locomotive is the better installation.

This presupposes that power lines are fairly near the

section and that one will not have to wait a year or a year and a half to get a locomotive.

Close inspection of the curves in Fig. 2 will also show that there is a certain fairly definite limit to the number of cars handled, below which the cost per car increases rapidly. This limit can be taken from the curves by noting the point at which the curve from right to left deviates from practically a straight line. Thus, for instance, in the case of the one driver and one mule curve, the line is practically straight from the right-hand side of the figure to the 10 or 12 car point, and from here turns rapidly into a curve. This possibly is better illustrated by Table II. These figures give the costs per car for the various organizations or units.

Taking the limit for the differences or decrease in cost per car at 4c., we see that 12 cars must be handled by one driver and one mule, 18 cars by one driver, one runner and three mules, etc., before this limit is reached. Taking 2c. as the limit, 16 cars must be handled by one driver and one mule, and a corresponding number by other units before reaching this limiting figure.

A further study of these curves will bring out other applications, but great care must be taken in their practical use as, unless the actual mining conditions are clearly understood and the practical working limits of the various organizations carefully taken into consideration, the curves may show a low cost for an impractical organization, or transportation unit.

Mauch Chunk, Pennsylvania, in 1845—Shipping point for the Lehigh Coal and Navigation Company *—From an old print*

The Story of Coal

By W. B. Richards, M.E.
Lansford, Penn.

WHAT is probably the first reference to coal as a fuel is found in the Bible (Proverbs XXVI, 21) in the words: "As coals are to burning coals and wood to fire, so is a contentious man to kindle strife." This particular sentence was written in 1016 B.C., at the time King Solomon came into power. Part of this ruler's domain consisted of Syria, and near the present City of Beruit coal mines were worked at that time. Coal is being mined there to this day.

The earliest notice we find of stone coal is in 371 B.C., at which time Theophrastus, a Greek author, mentions *Lithanthrax* as being found at Ellis and refers to its use by the smiths of that period. In England tools and cinders have been found in the excavations near the Roman Wall, indicating that the Britons were familiar with the use of coal prior to the Roman Invasion in 54 B.C.

The first actual record of a coal transaction exists in the form of a receipt for twelve cartloads of coal, which was given by the Good Abbott of Peterborough, in England, in 852. At about this time the monks of Belgium mined the "earth fuel" and used it for manufacturing purposes.

In 1239 King Henry III of England granted the privilege of digging coal to the good men of Newcastle. By a proclamation of Edward the First, and again in the reign of Queen Elizabeth, stone coal was prohibited to be used in London during the sitting of Parliament lest the health of the Knights of the Squire should suffer during their residence in the metropolis. In 1316 the Parliament petitioned King Edward II to prohibit the use of coal, and a proclamation was accordingly issued against it. Owing to the high price of wood, however, its use gradually became general in London.

Coal was used in the City of Paris in 1520. The fuel was shipped to France from the mines of Newcastle, in England. At the outset it met with little favor in Paris, as for some time was the case in London, owing to the difficulty attending its application. The coal was submitted to the Faculty of Medicine at this time, to ascertain if the new fuel would be injurious to the public health.

In America the existence of coal was proved by the French explorers at an early date. Father Louis Hennepin, Franciscan missionary, and chronicler of La Salle's expedition of 1678-1679, was the first to preach the gospel on the Niagara frontier and was the first who saw and described the Falls of Niagara. He knew of the existence of coal in 1679. On a map made by him is shown a "cole" mine above Fort Crevecour, on the Illinois River, near the present site of Ottawa. In his journal he states that in the country then occupied by the Pimitoui Indians there were mines of coal, which is the earliest record of the existence of coal in America. Father Hennepin also marks the site of a coal mine on the James River, near Richmond, Virginia.

In the Atlantic Coast Triassic coal field lies the Richmond Basin. This basin contains the oldest worked mine in America, and the first systematic coal mining in the United States was carried on within its borders. Coal was used in America as early as 1750, and in 1779 shipments were made to northern cities. The use of coal at that time was credited with lessening the febrile ailments of the inhabitants. During the War of Independence it was used at Westham, on the James

River, five miles above Richmond, for the manufacture of shot and shell. This plant was destroyed by the traitor Arnold in 1781.

At what precise period the bituminous coal of western Pennsylvania first came into use is not known. In 1684 privilege was granted by William Penn to mine coal in Pittsburgh. The earliest record of coal mining in the Pittsburgh region is that supplied by Thomas Hutchins, who visited Fort Pitt (now Pittsburgh) in 1760 and found a "cole" mine opened on the west side of the Monongahela River.

In 1775 S. Boyd took up and patented a tract of land to mine coal. In 1804 coal was shipped from mines at the headwaters of the Susquehanna River (near the present site of Clearfield) and the Indian village of Chincleclamoose down the Susquehanna River. It was sent down by Mr. Boyd and was landed at Columbus, a distance of 260 miles. It was a matter of great surprise to the inhabitants of Lancaster County to see an article with which they were wholly unacquainted brought to their door. In 1828 the first cargo of Pennsylvania bituminous coal reached Philadelphia from Karthaus, and some was forwarded to Baltimore.

Discovery of Anthracite Coal

Anthracite coal was discovered in Rhode Island in 1760. In 1762 the existence of coal in the Wyoming Valley of Pennsylvania was proved by the pioneers who had migrated from Connecticut to that region. It was found at the mouth of Mill Creek, on the Susquehanna River, near the present site of Wilkes-Barre. The Indians who inhabited eastern Pennsylvania knew of the existence of anthracite coal long before it was discovered by the white settlers, and made use of it only for pipe heads.

In 1769 Obadiah Gore, a blacksmith, was the first to use anthracite coal. He tried it in his forge and found it to give satisfaction. During 1775 mines were opened and the first shipment of hard coal was sent down the Susquehanna in boats from Wilkes-Barre to Harris Ferry, now Harrisburg; from here it was hauled in wagons to the arsenal at Carlisle, for use in the manufacture of munitions of war. These shipments were continued annually during the Revolutionary War.

Coal was discovered in the Pennsylvania Schuylkill Region in 1790, at the foot of Broad Mountain north of Pottsville, by Nick Allen, a noted hunter. He came from the New England states and was called the "black Yankee." During one of his hunting expeditions Allen had camped for the night under the shelter of some overhanging rocks and trees. He built a fire on top of fallen rocks and laid down near the fire to sleep. Some time during the night he was awakened by more heat about his legs than was comfortable, and getting up he found the stones red hot. Examining the rocks lying around, he found them black and shining, and came to the conclusion that these were stone coal, of which he had heard. He reported his discovery to the settlers in the vicinity.

Coal was discovered by Philip Ginter, a hunter, in 1791, at the present site of Summit Hill; this section is near Mauch Chunk (the Indian name meaning Bear Mountain) at the eastern extremity of the southern anthracite region. Ginter had built a rough log cabin in the forest and depended solely on the proceeds of his rifle for the support of himself and family. The game he shot included deer and bear, which he carried to the nearest store and bartered for the other necessities of life.

While returning from a hunting trip he discovered the black dirt that covered the coal bed and reported the extraordinary appearance to Jacob Weiss, an intelligent gentleman who lived at what was then known as Fort Allen (now Weisport), which was within 12 miles of the spot. An examination was immediately made and a small shaft sunk. Good coal was found at 10 feet from the surface.

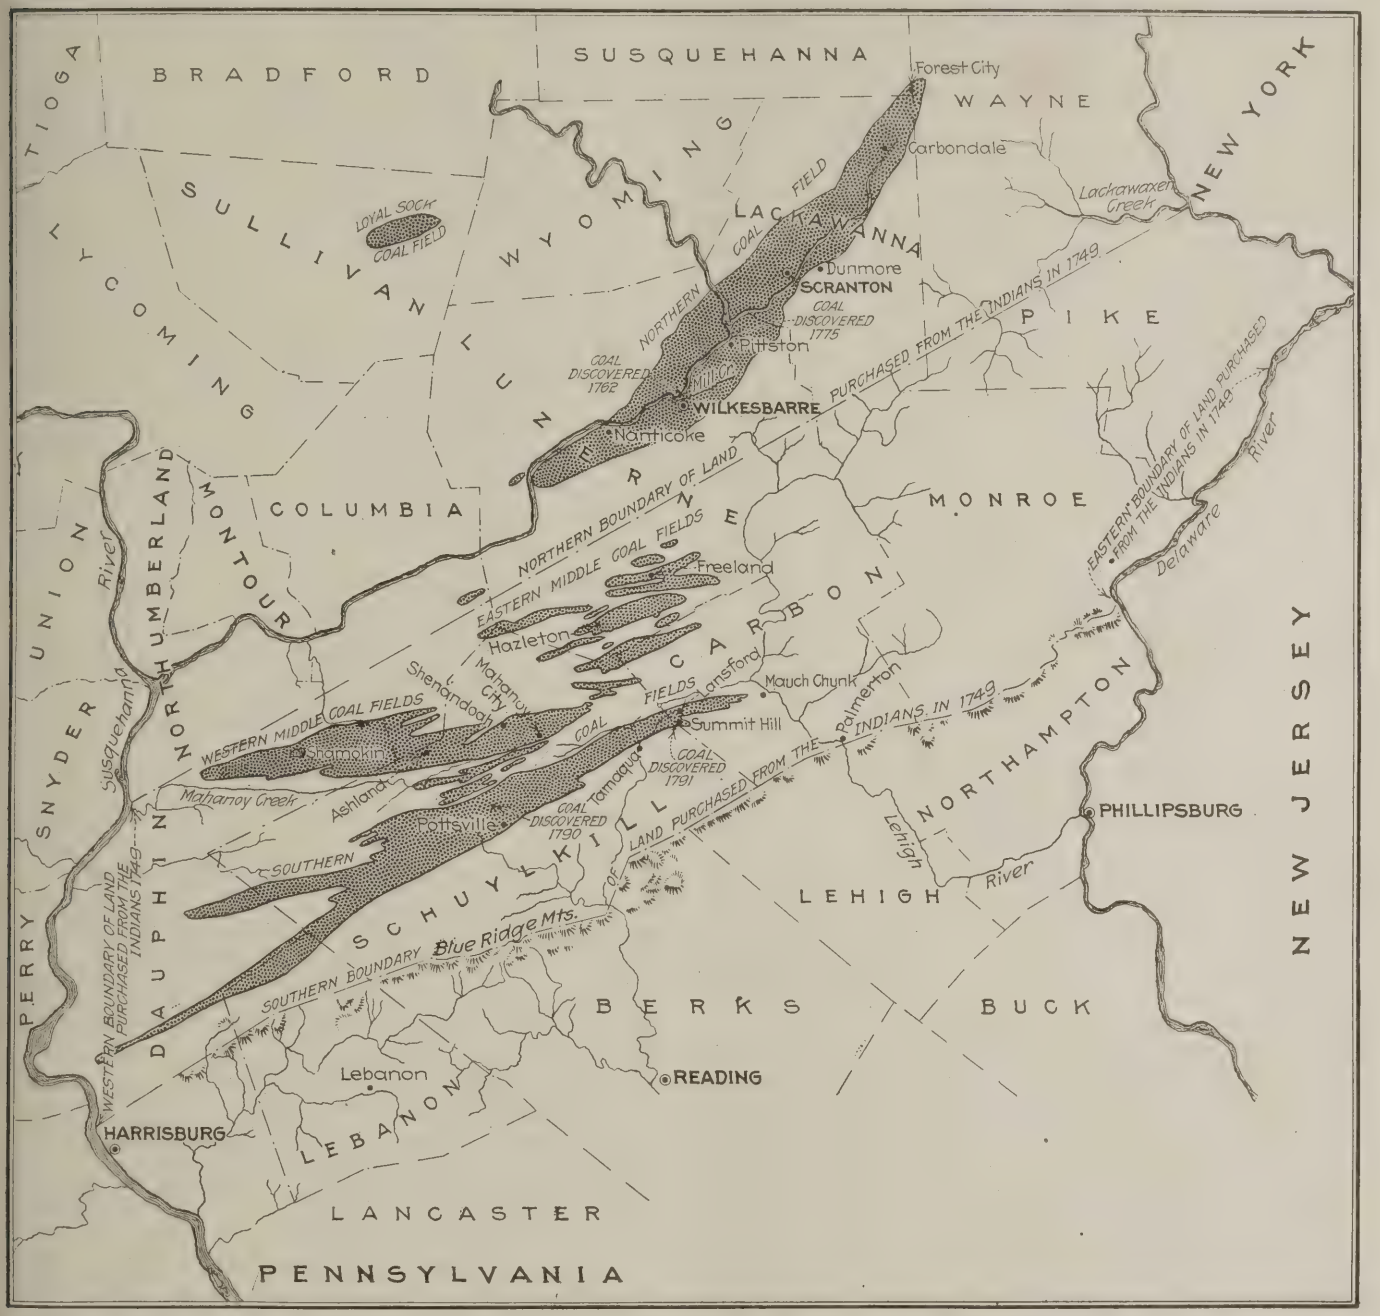
Taking a keen interest in the discovery, Colonel Weiss immediately took specimens of the coal to Philadelphia and submitted them to John Nicholson, Michael Hillegas and Charles Cist, the last named a printer, of more than ordinary intelligence, who pronounced it to be the purest of anthracite coal and authorized Colonel Weiss to reward Ginter for his discovery. Ginter was accordingly given the title to a small tract of land, upon which he built a mill; however, he was shortly after deprived of this tract by the claims of a prior survey.

Hillegas, Weiss and Cist, in 1793, formed the Lehigh Coal Mining Co. They purchased for Jacob Weiss the tract of land upon which Summit Hill is now located, and afterward took up under warrant from the Commonwealth about 10,000 acres of unlocated lands, including the Mauch Chunk Mountain, embracing most of the lands now owned by the Lehigh Coal and Navigation Co. This was the beginning of the Old Company, and from that day to the present coal from these mines has been justly famed because of its purity and high calorific value.

Construct Road to Mauch Chunk

In 1793 one of the company and four miners started mining at the site of the old quarry, and an appropriation was made of £10 ($26.67) in Pennsylvania currency to construct a road nine miles long to Mauch Chunk. The coal opening was in the midst of a wild and mountainous region, surrounded by forests and only traversed by the war paths of the Indians or the trails of the hunter. The nearest market was Philadelphia, over 100 miles distant.

Many fruitless attempts were made to get coal to market over the company's road, and thence by the Lehigh River, which in seasons of low water in its unimproved state defied the floating of a canoe over its rocky bed. The difficulty of kindling the coal made its introduction anything but easy, and after calling for contributions of money from the stockholders until calling was useless, the Lehigh Coal Mining Co. became tired of the experiment and temporarily gave up in disgust.



It is an interesting matter of record that in 1788 nails were made with the aid of anthracite coal by Judge Fell of Wilkes-Barre. In 1803 the Lehigh Coal Mining Co. made another effort and sent two arkloads of coal to Philadelphia. The fuel was tried, but could not be burned, and it was rejected as worthless. The spurned material was then utilized in the making of walks, and the "black rocks" of the Lehigh Coal Mining Co came in for much suspicion and ridicule at this time.

In 1805 John and Obadiah Smith, from Derby, Conn., settled in Plymouth, Penn. They bought coal lands and immediately began shipping coal by arks to points along

the lower Susquehanna River. In 1806 William Turnbill constructed an ark (a rough timber boat) to carry about 200 tons of coal via the Lehigh River to Philadelphia. Some of this coal was sold to the manager of the Philadelphia Water Works, but because of his inexperience in handling the fuel, which seemed to extinguish the fire, it was rejected as worthless. In 1808, under the direction of Judge Fell, grates were constructed at Wilkes-Barre to burn anthracite coal for domestic purposes.

In 1812 Col. George Shoemaker, of Pottsville, loaded nine wagons of coal from his mines at Centersville, about a mile from Pottsville, and proceeded to Philadelphia with them, hoping to find a market. But the opinion of the Philadelphians in regard to anthracite, or stone coal, was very unfavorable at that period—the frequent and persistent attempts to impose rocks on them for coal had aroused their indignation—and Colonel Shoemaker was denounced as a knave and a scoundrel. Colonel Shoemaker persisted, however, and disposed of two loads at the cost of transportation, one to Messrs. White and Hazard, of the Fairmount Nail and Wire Works, at the Falls of the Schuylkill, and one to the Delaware County Rolling Mill. Part of the remaining seven loads he sold for a trifle to some blacksmiths, who promised to try it; the rest he gave away.

Though Shoemaker lost money and went to considerable trouble in his attempts to introduce the fuel, the very men to whom he gave his coal obtained a writ from the authorities of the city for his arrest as an impostor and a swindler, and Colonel Shoemaker was forced to beat a hasty retreat. He only saved himself from prosecution by taking a wide circuit around the Quaker City

MAP OF EASTERN MIDDLE, WESTERN MIDDLE, SOUTHERN AND NORTHERN ANTHRACITE COAL BASINS

The two Middle and Southern basins were purchased from the Indians by the proprietary Government in 1749 for £500. The Northern coal basin together with the bituminous coal fields in Pennsylvania, were purchased from the Indians by the Penn family for $10,000.

on his way home. Such were the trials and tribulations suffered by some of the early pioneers in the anthracite coal industry!

In the meantime Mr. White, who was anxious to succeed in burning this coal, and some of his men spent a whole morning in trying to ignite it and raise a heat in one of their furnaces. They tried every possible expedient which skill and experience in other fuels would suggest. They raked it and poked it and stirred it and blew upon the surface through open furnace doors with perseverance and persistent determination, but all to no purpose. Colonel Shoemaker's rocks would not burn, so the attempt was abandoned and the door slammed shut. Returning from dinner at the usual time, all hands were astonished at the phenomenon which they beheld on opening the doors of the furnace. A glowing mass at white heat was discovered; so hot a fire had never been seen in the furnace before. Thus the secret of proper draft was discovered, and from this time anthracite, or stone coal, found friends and advocates in Philadelphia. The motto "Let it alone" became a receipt for its use, rather than its abuse. The result of this success got into the press, and as usual soon gave it a reputation. Everybody knew stone coal was coal, now that somebody had proved it such.

Shortly before this time, when an act was about to be passed authorizing the improvement of the Schuylkill River in order to convey coal to Philadelphia, the representative of Schuylkill County in the State Senate declared that there was no coal in his district, that there was a kind of black stone called coal, but that it would not burn.

Leased Property for One Ear of Corn

In 1813 Messrs. Miner, Cist and Robinson opened mines at Room Run and Summit Hill. On Aug. 9, 1814, the first ark with 24 tons was started to Philadelphia on the Lehigh River. The coal cost $14 per ton delivered at Philadelphia. Josiah White bought some of this coal and used it in his works. When the War of 1812 was over, anthracite could not compete in price with bituminous, and the mines were abandoned.

In 1817 Josiah White and Erskine Hazard, being desirous of supplying their works with anthracite coal, secured a lease from the Lehigh Coal Mining Co. for twenty years on its whole property, on the condition that after a given time for preparation they should deliver for their own benefit at least 40,000 bushels of coal annually to Philadelphia and the outlying districts, and that they should pay on demand one ear of corn as an annual rental for the property.

On Mar. 20, 1818, by an act of the Legislature, White and Hazard were granted the authority to improve the navigation of the Lehigh River from Stoddartsville to Easton, with instruments borrowed of the Delaware and Schuylkill Canal Co., the only instruments to be had at that time in Philadelphia. Having taken the levels from the river to the coal mines to ascertain that a road could be constructed on a descending grade from the mines to navigation, and being satisfied that it was feasible to make the necessary improvements, the next step was to raise the capital for carrying on the work.

On Oct. 21, 1818, the Lehigh Navigation Co., was formed with a capital of $50,000, for the purpose of making a road from the river to the mines in order to transport the coal to market. The road, including the road to the Summit Mines, was laid out in the fall of 1818 and finished in 1819. It was intended to use it as a railroad as soon as the business would warrant the expense of placing rails upon it.

On Apr. 21, 1820, the Lehigh Coal Mining Co. and the Lehigh Navigation Co. agreed to amalgamate their interests under the title of the Lehigh Navigation and Coal Co., and an additional sum of $30,000 was subscribed to the stock. With this aid the road was repaired and 365 tons of coal were sent to market. This quantity overstocked the market and was disposed of with great difficulty, the price asked therefor being $8.40 per ton. No anthracite coal came to market regularly from any other source than the Lehigh before the year 1825, and the reports of the anthracite coal trade began in 1820, when 365 tons were shipped to Philadelphia.

In May, 1821, the title of the company was changed to the Lehigh Coal and Navigation Co., and the stock of the old mine company was bought up by the new organization. The Lehigh stock generally stood high in the market, as Summit Hill was supposed to be all coal; but when it was learned that the bottom of the coal was found at 60 feet, the value of the stock depreciated 25 per cent.

First Stripping Operation in America

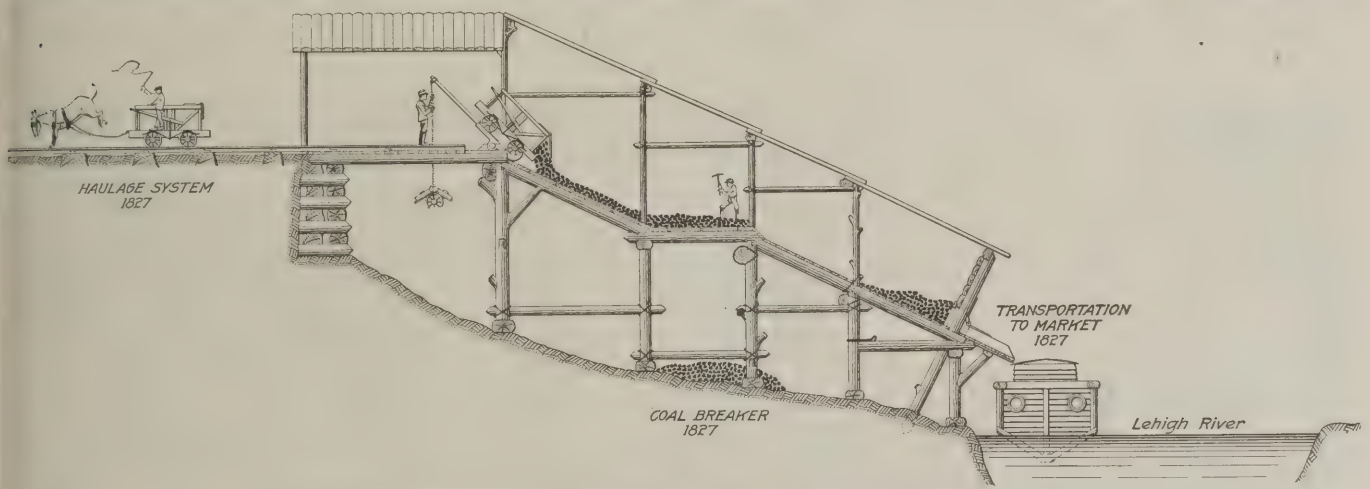
In 1821, 1073 tons were shipped to market. In 1821 a large quantity of coal was uncovered at the old quarry at Summit Hill by removing from its surface 6 to 20 feet of earth and slate. This process was continued until the excavation had a superficial area of 10 acres and a depth varying from 30 to 70 feet. The coal was uncovered and laid open to view, and it was worked in the open as in a stone quarry. The excavation was entered at different points by roads cut through the coal, in some places down to a depth of 70 feet. The vein ranged from 50 to 70 feet in thickness. The covering increased rapidly from the crest of the anticlinal, or saddle, to the synclinal, or basin, and it was found more economical eventually to excavate the coal by the ordinary process of mining by slopes than by the old or original mode of quarrying. This was the first stripping operation in America.

This remarkable exposition of an enormous mass of anthracite for a time excited much attention, not only in the United States but in Europe. It was a scene not presented by any other mining district in the world. For here a single vein reached the enormous maximum thickness of 70 feet, or equal to the workable thickness of the entire formation of the richest coal fields of the old world. This quarry was abandoned in 1847. The excavation, or place formerly occupied by the quarry, will cover an area of about 35 acres, and the amount of coal shipped from it will probably exceed 2,000,000 tons.

In 1822 a total of 2240 tons were shipped to market. The boats used in this descending navigation consisted of square boxes 18 ft. wide and 25 ft. long These boats made but one trip and were broken up in the city and the planks sold for lumber, the spikes, hinges and other iron work being returned to Mauch Chunk by land, a distance of 80 miles.

In 1823 anthracite coal was shipped to the New England states from Philadelphia by boats. In 1824 the Lehigh Coal and Navigation Co. started the great enterprise of driving the old Hacklebernie tunnel. This tunnel was 16 ft. wide and 8 ft. high, and was driven 790 ft. through hard conglomerate rock. The company engineers were under the impression that the coal found in this tunnel would dip to the south, but when the veins were cut it was found that they dipped to the north. The tunnel was abandoned until 1844, when it was completed. This tunnel in 1824 cost $34 per lineal foot. It was the first tunnel of its size driven in the United States.

In 1825 the demand for coal increased so much that 25,500 tons were sent down the Lehigh. The Schuylkill Canal was completed from Port Carbon to Philadelphia and 7143 tons were sent down the Schuylkill. This marked the turning point in the use of anthracite coal. People were now becoming accustomed to the new fuel, and the prejudice against it was fast dying out. The wood stove was beginning to be replaced by the coal stove, and it was during this year that firebricks were made.



In 1826 there were 31,280 tons of coal sent to market down the Lehigh. The business was now becoming so large that it was difficult to keep the turnpike to the mines in good working order without coating it with stone, and it was determined that the best economy would be to convert it into a railroad. The only railroad then in the United States was the Quincy, made in the fall of 1826, and which was about three miles in length. There had previously been a short wooden railroad about three-fourths of a mile in length at Leipers' stone quarry, but it was now worn out and not in use.

The railroad from Mauch Chunk to Summit Mines was commenced in January and completely in operation by May, 1827. It was nine miles in length and had a descent all the way from Summit Mines to the river. The whole transportation of the coal upon it was done by gravity, the empty wagons being returned to the mines by mules, which rode down with the coal. When the wagons reached Mauch Chunk they were run down a gravity plane to a point near the river, where the coal was dumped into a chute, from which it was loaded into a boat or ark.

When the mules rode down four were placed in a wagon and seven wagons were connected into one train. This was coupled to the coal wagons and made the descent at the same time. The mules readily performed their duty of drawing up the empty cars, but having experienced the comfort of riding down they seemed to regard it as a right, and were reluctant to descend in any other way.

In 1829 the Lehigh Canal was opened from Mauch Chunk to Easton, and from White Haven to Mauch Chunk in 1837. In the same year the Baltimore Coal Co. was organized at Wilkes-Barre to mine coal. In 1832 the little Schuylkill began to be used for the transportation of coal from the Tamaqua region. In 1837 Beaver Meadow made the first shipment of coal. This was followed by Hazleton in 1838 and by Shamokin and Lykens in 1839. In 1834 the Lehigh & Susquehanna R.R. was completed, and in 1846 coal was shipped from the Wyoming region by the Lehigh & Susquehanna R.R. and the Lehigh Canal.

In 1839 Garrett and Eastwick successfully used anthracite coal in their locomotives on the Columbia R.R.

PRIMITIVE METHOD OF LOADING ANTHRACITE INTO BARGES IN 1827

In 1841 Dr. Casenhammer applied for a patent for making pig iron with anthracite. In 1838 it was used for this purpose at Mauch Chunk and Pottsville.

In 1843 great improvements were introduced in the preparation of broken coal. Revolving cast-iron cylindrical crates propelled by steam power were used for this purpose, and improved revolving screens were installed at the landing at Mauch Chunk and were driven by water, assorting the sizes and freeing them from dirt and impurities. The primitive breaker was a sledge in the hands of a brawny workman, who broke up the large lumps for market. It was in this manner that the term breaker was derived. In 1845 railroads were built by numerous companies, and the coal trade began to boom from then on.

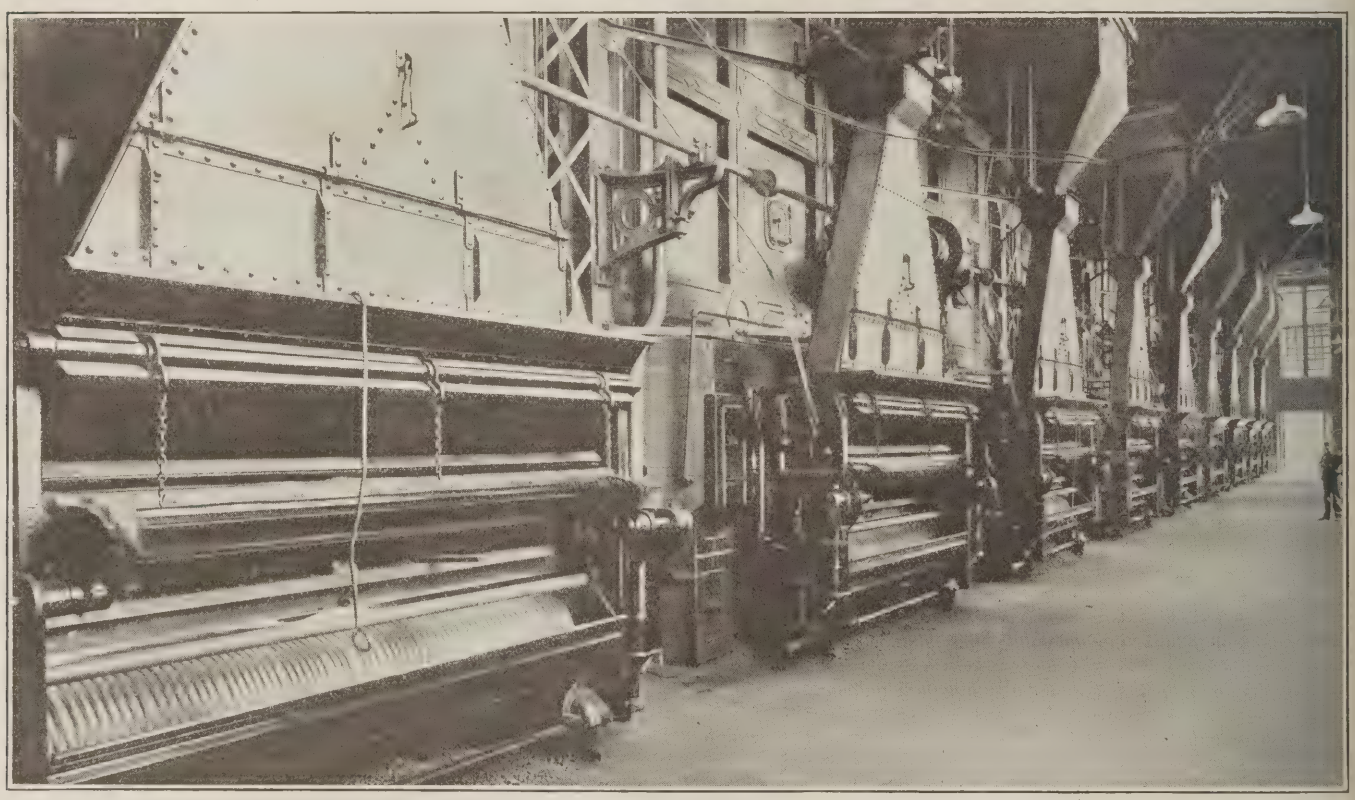
It is strange to relate that near the spot where coal was discovered in 1791 by Philip Ginter a slope was sunk in 1847 in the Mammoth Vein, which was 50 ft. thick to the synclinal axis. In February, 1859, a fire, said to be of incendiary origin, broke out and altogether a large sum of money has been expended in the attempt to extinguish it. It has burned a mile in length and 1500 ft. wide, and has consumed millions of tons of coal. The fire is now confined east to the spoon end of the basin by a fire barrier of clay down to the level of the water in the old mine workings.

Selection of Stokers at Mines

By T. A. Marsh
Chicago, Ill.

SYNOPSIS — *The selection of stokers for use at coal-mine boiler plants must be made with care. Not only should low-grade fuel be burned, but no change can be made in the fuel if a wrong selection of stoker is made. To be thoroughly successful on low-grade fuels, a stoker should be entirely automatic.*

ALTHOUGH coal at the mines is plentiful and cheap, there is no reason why the practice of economy in its use should be neglected. In fact, there are certain considerations requiring more attention to items of economy in combustion at mine installations than elsewhere.



From an engineering as well as from a commercial standpoint, the selection of all steam-generating apparatus, but particularly that of stokers for coal mines, varies distinctly from the considerations influencing such selections in other localities.

The first and basic distinction is that if the purchaser in other localities selects a type of stoker unsuitable to his ordinary of accustomed coal, he can usually vary his fuel over a more or less liberal ra- dependent on the locality. In Chicago he can selec- from the various grades of Indiana and Illinois washed and raw coals. In Omaha he has a choice of Kansas, Iowa and Wyoming fuels. In St. Paul he has Illinois and Youghiogheny, Hocking and various grades of West Virginia and Kentucky coals from which to select. Correspondingly, practically every market offers some selection, and there is no secret to the fact that many a misjudged choice of stokers has been made to operate successfully through the purchase of selected coal frequently at prices above the minimum per 1000 B.t.u. existing for steam fuel.

The coal producer has no such alternative. He is bound to his own coal, and he must select a stoker suitable for its use or admit his error and change the stoker. He cannot change his fuel, although he may at times so desire.

A second consideration affecting the selection of stokers by coal producers is that the stoker selected should be capable of burning the lowest grades of fuel produced at the mines. Culm, washery refuse, bug-dust, No. 5 and, in fact, any combustible mine product not generally salable should be the natural fuel for stokers at the mines. This requires the selection of stokers not subject to clinker troubles. They should possess liberal grate areas and a generous draft supply. Without such provision, the mine plant will be forced to use the better grades of commercial coal, every ton of which has a distinct market value. With proper stokers and engineering, on the other hand, the fuel costs will amount to practically nothing, since a fuel may be used that has no definite commercial value.

A third consideration is that a type of stoker should be installed that is best adapted to the fuel, in order that the coal company's sales and engineering organiza-

INSTALLATION OF CHAIN GRATE STOKERS AT A LARGE BOILER PLANT

tions may become familiar with the possibility of burning the various sizes and grades of steam coal that are produced and in order that they may be fortified with facts obtained from their own company's power plant. If anyone ought to know the characteristics of a fuel, it is the producer of that fuel; and if he cannot select a type of stoker that will give good furnace conditions, what hope is there for the purchaser of this coal with only a casual knowledge of its properties and behavior?

A final but not to be neglected consideration is that the record and appearance of the mine power plant as well as the fact of burning the poorest grade of coal produced at the mine should be positive sales arguments for the fuel. What can be more convincing to a prospective purchaser of 1¼ in. screenings than figures showing him combustion rates, evaporation and horsepowers developed with this same fuel, and at a plant where he may be taken at any time for a thorough inspection of firing conditions.

The mine plant should therefore be a well designed one—in fact a "show" plant. Complete records should be kept of results; but above all, first, last and always, the correct type of stoker must be selected. The producer cannot take a chance with clinker-producing stokers. These would at once condemn the fuel. Let others who have a wide coal market experiment with stokers which involve a selection of coal on the basis of fusibility of ash. The producer cannot take a chance. He must use good engineering, which is simply common sense.

Mine Plant Stoker Should Be Automatic

The stoker for a mine plant should be automatic. It should feed the coal, burn it, discharge the ash and keep the air spaces in the grate always ready for the fresh fuel. Few types of stokers are strictly automatic; most of them push coal into a furnace and trust to someone to dump or pull ash, clinker and live coal out at a later date.

A stoker well adapted to low grade fuels as well as being low in operating cost and absolutely free from clinker trouble is the chain grate type. With the chain grate, coal is fed and burned; the ash is discharged to the pit and the air space automatically cleaned for the incoming fuel.

This type of stoker has been developed for and has been demonstrated to be well adapted to mine use with high ash clinkering coals. Originally designed for free burning coal, popular demand required a chain grate design for the coking coals. Accordingly, the "L" type chain grate was developed, embodying the chain grate principle of ash discharge and cleaning of air space with the breaking up action required by coking coal. Both types of these stokers have produced unusually high operating efficiencies and capacities. They are distinguished by freedom from clinkers, low labor and maintenance costs.

The plant at the mine is a problem by itself and cannot be judged by the usual considerations. A full appreciation of the problem and of the possibilities of a proper installation will lead to better plants and a greater return on the investment, not only as regards saving in fuel, but also as regards the marketing of steam coal.

Great Britain Relies on Foreign Countries for Supply of Mine Timber

By Mark Meredith
Liverpool, England

Lovers of the out-of-doors who wring their hands over the stripping of Britain's woods know, of course, that there is a patriotic necessity for the havoc, but they probably hardly realize how urgent the need is. Some facts in respect to England's position in regard to pit wood will enlighten them.

In the first place it has to be borne in mind that as one of the greatest coal producing countries in the world Great Britain is also one of the greatest consumers of pit wood. During the five years, 1909-13, the consumption of pit wood in the United Kingdom was about 3¾ million tons per annum. In 1913 it was roughly 4¼ million tons. For the greater part of this Great Britain had to rely on foreign countries, only 750,000 tons being home-grown timber.

Thus in normal times Great Britain imported some three million tons of timber per year. Of this over 1¼ million tons came from Russia, 820,000 tons from France, 446,000 tons from Sweden and Norway, and 392,000 tons from Spain and Portugal. As none was imported from other parts of the Empire, it will be seen that for at least 80 per cent. of its supply of pit wood the United Kingdom is dependent on foreign countries, a dependence that although, as it happened, was confined to the Allies and to neutrals, quickly proved unsatisfactory once war broke out.

It soon became evident that the supply, particularly from the Baltic, would be curtailed, and inquiries were therefore made with a view to ascertaining whether some part of the deficit could not be made up by obtaining supplies from Newfoundland and Canada. The Board of Trade representative on the mission of inquiry reported that there is an almost inexhaustible quantity of timber in certain parts of Newfoundland and the Maritime Provinces of Canada, much of which could be made available for pit props.

The real factor as to quantities procurable from these sources resolves itself into a question of cost of carriage. At the present moment, however, the question is not one of cost of carriage, but of the practicability of carriage.

Probably the cost of carriage had a deciding influence in 1915, when the shipping difficulties had not become so acute, for in that year, while the quantity of pit wood available from Canada and Newfoundland was 950,000 tons, less than 100,000 tons of it was actually imported. Newfoundland's share was 86,000 tons, which shows that the Canadian resources had scarcely been tapped. Grim necessity has compelled Great Britain to strip her own scanty timber resources, while the extended use of steel and concrete props in substitution for wood, especially on main roads and airways, has also helped Great Britain mines to continue operations.

If Great Britain must go abroad for her supplies after the war, it is to be hoped that her resources within the empire will not be forgotten, although it must be admitted the cost of carriage will not be a negligible factor even in normal times. It has been estimated that Newfoundland could eventually supply at least some 750,000 tons annually, and Canada much more.

Mining Institute Discusses Anthracite Prices

THE winter session of the American Institute of Mining Engineers (now, by the way, to be known henceforth as the American Institute of Mining and Metallurgical Engineers) was made notable by the paper of R. V. Norris on anthracite mining costs. As some of the speakers pointed out, many of the more important facts of the anthracite situation lie deeply hidden in Mr. Norris' figures. E. W. Parker, director of the Anthracite Bureau of Information, in his remarks called attention to the fact that 25 per cent. of the whole production of anthracite was priced at so low a figure that it had to be sold below its actual mining cost.

It was stated that when increases in wages were made the prices were advanced less than the computed average increase in costs due to the wage increase. The advances made no allowance for increases in the cost of materials that the operator had to purchase and, as said, only partially met what had been figured as the probable average increase in the cost of production.

Unfortunately, after one increase in wage when the adjustment was figured as 45c., the actual increase given was only 35c. It proved, however, that the increase should have been over 70c. The efficiency of labor probably had much to do with the miscalculation, for even though patriotism did a great deal to make the men willing and efficient workers, it could not give old men the energy of youth, or newly employed men the dexterity of the experienced. The young men and the experienced were being continually withdrawn leaving less capable men to take over the burden.

Sixty Per Cent. of Anthracite Mined at Loss

S. D. Warriner, president of the Lehigh Coal and Navigation Co., declared that 60 per cent. of the anthracite coal was being mined at a financial loss when all charges were considered, including depreciation, depletion, a reasonable interest on investment and Federal taxation. He said that only the fresh-mined coal should be considered in sizing up the situation, and that his estimate of 60 per cent. would be inadequate during the period of slow work now upon us.

An attack being made upon the preparation irregularities during the war, Paul Sterling declared for the company of which he is mechanical engineer (the Lehigh Valley Coal Co.) that it had maintained its standards inviolate throughout that period of stress.

R. V. Norris said that the anthracite mines had been conducted during the war with production alone in view. As a result development had suffered and the anthracite companies were faced with a large expenditure for the extension of tunnels and gangways.

Edwin Ludlow declared that enlistments of the men, especially in the mechanic class, had reduced the efficiency of labor. Some men also had taken advantage of the fact that the company was unwilling to discharge anyone who would work even supinely during the period of the war. The right of discharge had practically rested as an unused corrective ever since the United States entered the conflict. Increases in wages had produced not greater efficiency, but in too many cases the reverse. The output of certain collieries, he stated, had declined during the war 0.26 tons per man-hour, despite all efforts to increase unit output.

He said that a certain corporation having a payroll of about $8,000,000 a year had to pay an increase of $3,000,000 a year to labor. To meet this large sum it had been allowed to charge an increase on prepared sizes of $1,500,000 per annum. Thus $1,500,000 of a loss was incurred. However, there seemed a hope that this loss might be in part averted, for the business in steam sizes was then brisk and profitable. But the profit from steam sizes was wiped out by the increased cost of material, which loss alone was $960,000.

He prophesied that the survival of the fittest would wipe out many anthracite companies and operations of size and importance, which before the war were able to exist. With post-war conditions, unless prices were raised, they would have to close their operations. Should such a closing down result, there would be a runaway market this fall, for it is absolutely necessary that the fittest and the less fit in the anthracite industry be alike kept in existence if the urgent needs of the public are to be met, during and before any normal winter.

Inequitable Rates Put Mines Out of Business

It may here be said that an increase of prices equivalent to the *average* advance in wages cannot be made with fairness to the higher-cost operators where the difference in difficulties in operation are as large as those existing in the anthracite region. Large changes in wage rates thus inequitably adjusted cannot do otherwise than put a lot of carefully managed mines out of business—mines which the public is most anxious to keep in active operation. The correction for increased average wage costs in the anthracite region was not so readily made as in the bituminous region, where the estimate proved itself correct with but 1c. of error.

James B. Neale read a paper on the "Work of the National Production Committee of the U. S. Fuel Administration," and said he hoped that the efficiency of the operator would be increased by moral considerations and by a continuance of the work of the new production committees or something equivalent thereto. R. Dawson Hall stated that the economic basis of industry prevented the operator from yielding to those moral impulses toward efficiency as often as such moral impulses called on him.

The day laborer, if asked to do a larger and more efficient day's work, may do so because the appeal does not ask him to give anything entailing any loss. He works no more hours than he would if working less efficiently and he receives no less pay than he would if he loafed on the job. His efficiency, therefore, does not hurt him in any manner unless he is the kind of man to whom work is painful and abhorrent. The miner, on the other hand, when asked to be efficient, being on piece work, is sometimes quite willing, and indeed why should he not be? Efficiency, and the resultant increase in output, is reflected in his higher wages.

When, however, the operator tries to become so efficient that the miner gets all the cars he needs and all the cutting and loading facilities he can use, then there

has to be an excess of equipment, power and day labor. So efficiency in dealing with the miner means inefficiency as far as economical production of coal is concerned. The manager is confronted with larger costs of production, as his efficiency in supplying cars to miners is such an expensive matter to the company that he realizes that for him and the corporation it spells only a financial loss such as will inevitably be classed as inefficiency by the company.

The same is true when more efficient machinery for the undermining, drilling, face conveying and loading of coal is provided. There is also but little reward for the company which double-tracks rooms and headings to promote speedy car delivery or which introduces instantaneous ventilation and room car-pullers and electric lighting to facilitate the rapid extraction of coal.

Large tonnage, however, we are told spells low overhead. It does, if the orders are available and the miners will work a full day. If, however, the miner gets a frequent turn and every mining advantage, he is apt to come out at noon and so make the overhead come to the same percentage of production cost. But if he works there are apt to be more days of idleness, and the overhead charge again makes trouble.

Inefficiency in delivering cars to the miner is likely to continue until such time as the miner is paid wholly or partly by the day and not by the ton alone. With payment by the day, or partly by the day, the operator will not be complacent when he sees a miner waiting for cars, any more than he is happy in his mind when he sees a motorman lolling at the parting waiting for the arrival of gathering locomotives. Every efficient operator will then have his appropriate reward.

Nowadays the operator who gives the miner a generous car allotment and other equipment and power advantages soon realizes that his generosity is making him a weak opponent, in the market, of the man who seeks only to get out his coal at the lowest cost regardless of the desires and requirements of the enterprising miner. He also finds his day men disgruntled at the few hours in the working day that the average miner employed on the ton basis is willing to work when given prompt car service. There was no time for the discussion of these remarks by the assembly, but the Chair, R. V. Norris, registered the customary disapproval of such revolutionary remarks.

S. A. Taylor read J. D. A. Morrow's paper on "Distribution of Coal Under the United States Fuel Administration." Shortage of time, unfortunately, prevented a discussion of the paper.

The visit to the Federal shipping plant located at Kearny, N. J., occurred on the following day, Thursday, Feb. 20. The Federal Shipbuilding Co. was formed July, 1917, by the United States Steel Corporation, in order to assist in the great shipbuilding program being carried out by the United States Shipping Board for war purposes.

The plant is situated on the west bank of the Hackensack River, and comprises about 185 acres of land, originally a marsh which was practically covered by water at high tide. About 750,000 cu.yd. of fill was obtained by the excavation of the wet basin and by the dredging of the Hackensack River, after which a final top fill of cinders was applied.

The first pile was driven on Aug. 6, 1917, and the construction work was prosecuted in a most energetic manner, despite the severe winter and other difficulties. All of the facilities and organization of the United States Steel Corporation were generously placed at the service of the Federal Shipbuilding Co., which accounts for the remarkable and substantial progress made.

The plant is entirely self-contained, having 12 ways and a fitting-out basin capable of accommodating eight steamers at one time, besides the necessary workshops for carrying out every detail of manufacture required in ship construction.

Special attention has been paid to welfare work and safety appliances, as in the other subsidiary companies of the corporation. The first keel was laid in November, 1917, and up to the present time nine boats have been launched and six delivered. The sixth left for trial on the morning of the visit. These steamers are 410 ft. over all, 55-ft. beam, with a deep draft of 27 ft., carrying 9600 tons of cargo, and they will make a speed of 11½ knots loaded. Tests on the unloaded boats have shown a speed of 13 knots. Satisfactory results have been given by all the vessels delivered, and the boats are a fine type of the modern economical cargo carrier.

In order to make the greatest possible progress under war conditions, about 60 per cent. of the first thirty steamers was fabricated by the American Bridge Co., and sent into the plant all ready for erection; the remaining portions, consisting of the two ends, were fabricated in the plant.

During the early part of 1918, extensive preparations were made for carrying out experimental electric welding with the view of building steamers without rivets. This work was under the charge of the Emergency Fleet Corporation's Experimental Section, but on the signing of the armistice operations were suddenly stopped, and the equipment for electric welding is now dismantled and shipped away.

No attempt has been made to cover all the features in the program as the outlines of the occasion were duly covered in the advance notice published in the issue of Jan. 30, page 237. This early draft of the program was closely adhered to.

Kentenia Coal Sales Co.

In the Feb. 20 issue of *Coal Age*, p. 383, there appeared a news note stating that the Kentenia Coal Sales Co., of Pikeville, Ohio, had filed a petition in voluntary bankruptcy in the United States Court at Cincinnati. The coal company in question calls attention to the fact that this information is wholly incorrect. It appears that the Kentenia Coal Sales Co. is entirely solvent and is conducting a prosperous business. Our correspondent finds on investigation that the error grew out of the fact that the Kentenia Coal Sales Co. was one of three petitioning creditors who filed an involuntary bankruptcy petition against a Kentucky coal corporation. The news reporter who originally supplied the information to the *Coal Age* correspondent evidently did not know the difference between a petitioning creditor and a defendant in an involuntary bankruptcy proceeding. The error is regrettable, and *Coal Age* is giving the facts this prominent display in order that no injury shall result to the Kentenia company from the mistake.

Opportunities in South America for American Coal

As a result of the war, conditions are especially propitious for the extension of the American export coal trade to South America. This is the firm conviction of Grosvenor M. Jones, the assistant chief of the Bureau of Foreign and Domestic Commerce, who recently returned from a trip to South America, during which he made an intensive study of the region with respect to markets for American coal.

With the expansion of American foreign trade, which must come if the nation's ambition with regard to the merchant marine is realized, must come also an increase in sea-borne coal, in order to balance the freight movement. If American ships are to compete successfully with foreign shipping, means must be found to have cargoes each way. When one leg of the voyage must be made in ballast, the costs of operation become prohibitive for most trade. It has been said that English coal has made possible that nation's merchant marine. Conditions now have changed so as to limit the amount of English coal that can be sent to South America, while the United States is in a more advantageous position than ever to enter those markets. It frequently has been pointed out that France never can have a great merchant marine, since it cannot furnish the required bulk of outbound cargo. This does not apply to the United States, and it is to coal and to other products of the American mines that American exporters are looking to furnish the major part of an outbound freight.

Latin Americans, more than any other peoples, adhere to established customs in the purchase of goods. During the four years of the war they were forced to get their coal supplies from the United States. This has afforded an opportunity for the introduction of American coals into South America, and now that Latin American consumers have become accustomed to the fuel there is every reason to believe that the market can be retained.

While Cuba will continue to be the most important Latin American market for American coal, that of Argentina should rank a close second, Mr. Jones believes. The Cuban market has been made, to a large extent, by the activities of American enterprises. Capital from the United States is becoming increasingly interested in Argentine developments, which will make it easier to expand the demand for American coal; but during the war the almost unassailable preference for Cardiff coal on the part of most of the other consumers of fuel has given way to a decided appreciation of Pocahontas coal. Pocahontas coal was put to an exacting test by the Argentine Railways, with a most satisfactory result. The wide grate bars in use in South America make it advisable, Mr. Jones states, to screen the coal more carefully than has been the American custom. It is his opinion that the example of the English should be followed and all export coal be screened carefully at tidewater, where the fine material could be converted into briquets.

Briquets are popular throughout Latin America. Many consumers will buy nothing else. Fuel in this form can be piled up regularly, making pilfering easy of detection. This latter feature is one of great importance to Latin American coal consumers. With the price of coal high and with a general tendency toward pilfering among the lower classes, the safeguarding of the fuel pile is important and oftentimes difficult.

While two American companies, the Consolidation Coal Co. and the Pittsburgh Coal Co., are well entrenched at Buenos Aires, Mr. Jones declares it is absolutely necessary to pool interests under the Webb Act if the American producers are to capture a substantial part of the South American market.

Argentina offers a particularly promising field, in that the extension of railroad lines and the increasing demand for coal for industrial power plants will make continually for a greater market. The bunkering trade, already important, also is expected to assume greater proportions.

Montevideo, which is at the mouth of the Rio de la Plata, is better situated than are other Plata River ports. It is destined, many believe, to become an important bunkering point. It is easier of access for vessels of great draft, while the congestion that often exists at Buenos Aires is not met at Montevideo. In addition, there is an increasing demand for coal for use industrially in Uruguay. Brazil, Columbia and Venezuela offer less important east coast markets, but their needs as well are increasing along with the extension of railroads and construction of power-consuming public utilities and industrial plants.

West coast markets are not so promising as are those on the east coast, but in the aggregate a considerable tonnage of coal is consumed in those countries each year. Much of the bunkering trade on the west coast has fallen to the United States, because of the splendid facilities operated in connection with the Panama Canal.

The development of American mining enterprises has added greatly to the amount of coal imported, particularly by Chile. The great development in copper and iron requires large quantities of fuel. The transportation of these raw materials, as well as of tin and other products, requires a large amount of tonnage. These ships, on making the return trip from the United States, afford the service necessary to lay down American coal at west coast ports at prices that will compete with Australian coals. Since the amount of coal taken by the returning ore ships would be too great for any one port, plans are being made for the installation of the best of facilities at a central point from which the coal can be transshipped to smaller vessels and delivered at the numerous points where the coal is needed.

Fuel oil has been used extensively on the west coast of South America. The increasing price and the tendency on the part of American producers to make less fuel oil, in favor of the more valuable byproducts, are causing them to use less of that fuel.

Mineral Leasing Bill Talked to Death by Senator La Follette

The mineral leasing bill, which provided for the leasing and sale of coal lands on public domain, was talked to death by Senator La Follette, of Wisconsin. After the measure had passed the House and the Senate and had been the subject of long deliberation in conference, it was caught in the legislative jam of the expiring session. Even then four hours of the precious time was allotted to the discussion of the conference report. The greater part of this was used by Senator La Follette, who declared he was prepared to continue indefinitely. There were 65 votes pledged in the Senate for the measure, which insured its passage by a comfortable majority, had it been allowed to come to a vote.

Few bills have traveled a rockier road than have the measures providing for the leasing of mineral lands. Similar measures have passed the House and Senate on three occasions. The bill just killed, however, was the first on which the conferees had agreed. In fact, Senator Smoot, of Utah, was the only one of the ten conferees who objected to the conference report.

Senator Vardaman Scores the Anthracite Coal Operators in Report

Interference on the part of the Federal Government to divorce the transportation companies from the mining companies in the anthracite region of Pennsylvania is recommended in a report submitted to the Senate on Mar. 3 by Senator Vardaman, the chairman of the committee which has been investigating the coal situation.

The report points out that 72 per cent. of the anthracite is produced by eight transportation companies, "notwithstanding the fact that the constitution of Pennsylvania prohibits a transportation company from engaging in mining."

One of the things declared to have been proved at the hearings is that the Susquehanna Collieries Co. has taken over the Pennsylvania companies.

Much emphasis is laid upon what is termed the "dog-in-the-manger" attitude of the companies in reaching out for more leases when their own properties are to a great extent undeveloped.

The Fuel Administration is criticised for not using its "despotic" power to compel the reclaiming of coal from culm banks.

The Girard estate is being operated so as to be a curse to the householder, the report declares. It fixes the standard for high royalties, it is said, which makes for the condition wherein anthracite royalties are ten times those levied against bituminous lands. Royalties and freight rates need the attention of Congress, the report asserts, together with the "underlying cause of it all that one group of financiers control the anthracite production of the country.

"It is unfortunate," the report continues, "that the Federal Government cannot take control of coal mines and operate them for the benefit of all the people. The price of coal should be fixed by the Government and a fair return on investment also should be vouchsafed."

Deputies Named to Continue Compilation of Coal Traffic Statistics

W. D. McKinney and F. C. Honnold have been named deputy directors of the Bureau of Statistics of the Fuel Administration. This has been done so that they may continue the compilation of coal traffic figures along the lines formerly followed by the Ohio Bureau of Coal Statistics and the Illinois-Indiana Coal Traffic Bureau. These bureaus were railroad organizations. They were abandoned when the Government took over the roads. The work was taken over by the Fuel Administration on Apr. 1, so that necessary statistics could continue to be made available. In order that statistics for the entire coal year may be had, the work will be continued until after the March figures are all received.

Coal Seams in Matanuska Field Badly Broken and Faulted

Discussion of coal in Alaska brought about by the debate on the leasing bill led Secretary Lane to make the following statement in regard to the Matanuska field:

Two leases have been entered into by the Government, one with Lars Netland, a miner, who has as a backer Mr. Fontana, a business man of San Francisco, and the other to Oliver La Duke and associates. Neither of these parties has any other interests of any kind, so far as is known, in Alaska or any connection with any railroad, and neither of them has been successful in developing any large amount of coal. There are many thousands of acres in this field which are open for lease and which will be leased to any responsible parties who will undertake their development. There is no possibility of monopolizing this field, even if someone wished to do so, for the Government reserves are kept to be operated in case such monopoly should arise. Thus far, however, the Government in operating its own mine has been no more successful than the private lessees, for the coal is so badly broken and faulted that exploration work to follow the seam must be undertaken before development work can be wisely done. And this is being undertaken. Government experts who have examined this field do not promise without further exploring a larger output of coal from this field than 150,000 tons a year.

Problems in the Merchandising of Coal

By George H. Cushing
Managing Director, American Wholesale Coal Association, Washington, D. C.

IT IS a curious fact in American life that no man is expected to talk disinterestedly, or is believed capable of doing so, unless he is a United States judge. The latter is presumed to be truthful because, assumptively, he is supposed to have been bought off for life. All others must stand to have their words discounted on the theory of personal interest. Even presidents of the United States are not excepted. Their discussions are presumed to be tainted with that self-interest which has to do with an extension of term.

So, I suppose that when I discuss coal merchandising my word will be discounted liberally on the theory that I am talking the way I am paid. Even so, there is one most excellent reason why I cannot speak as I am supposed to do—for the coal jobbers. There are no coal jobbers any more. They all disappeared last November. They eliminated themselves from the earth to get rid of the stench of having been classified as purchasing agents. Therefore, since I cannot talk for some one who does not exist, I am not pleading for the jobbers.

Instead, I speak only for the "wholesalers." That is a most generous term. It embraces all who distribute coal in carload lots.

If by some process I may be allowed to divest myself of so mystifying a connection, and if permitted again to assume the rôle of a private citizen deeply interested in the safety, the welfare and the sanity of coal, I would like to discuss the Foreword on coal merchandising in the Feb. 13 issue of *Coal Age*.

It advised all coal operators to study carefully their merchandising programs. In that recommendation I concur most heartily. Nothing is more needed. Nothing that can possibly be done will pay bigger or surer dividends on the outlay. So, I say the recommendation is wise and sound.

Objections to Eliminating Existing Selling Machinery

But, if the further argument of the editorial means to advise operators to throw away the old selling equipment and install a new and untried system in these times of grave distress in coal, I ask leave to disagree. It isn't safe. It isn't good business.

My objection to that proposal is based on a common practice in business, to wit: No new piece of machinery, no matter how advanced in design or how economical in operation, ever completely and instantly supplants the old. Instead, there is always a period when the old is a receding factor and when the new is coming more and more into its own. This is so out of respect for the fact that it cost money to establish the old machinery and that it still is capable of some service, before it is junked. It is out of respect for the further fact that the new machine is untried. It must be given time to correct its small defects and to have its running parts smoothed off by use. Changes in machinery are made gradually, at least by careful men.

What is true of the machinery of a factory must be equally true of selling machinery of a coal mine. The new must have time to prove and perfect itself. The old must have time to liquidate its value.

I must demur, therefore, to the theory—now commonly expressed—that the so-called middleman in coal can be supplanted instantly. I do so on several accounts. Not the least of these is that it is no more safe to destroy one system of selling in the hope a better one will grow in its place than it is safe to adopt the principles of Bolshevism and destroy one form of government and one social order in the hope that something better will grow in its place. I say the two ideas are one. And, I say that both are equally and terribly dangerous.

This does not even pretend to say, however, that there is no room for improvement in the methods of selling coal. There is, in fact, both room and need for a revolution, or as near to it as we can get. One fact alone stamps the coal industry as deficient in this respect. We have no Marshall Field in the coal business. We haven't even a John Wanamaker. Certainly we have nothing approaching the Crane Company. There is not only plenty of room for one, but the coal trade will be behind the procession until it gets something of the sort.

A Few Beginnings in the Right Direction

We have, it is true, a few beginnings in the right direction. Williams & Peters are great merchants—in their line. They have been so for many years. But, their field is limited to a few grades of coal and that reduces their standing to less than that of a truly great house. The same, almost precisely, is true of the greatest coal merchandising house of them all—the Berwind-White interests. Its field has been too small even though its methods are great. Castner, Curran & Bullitt started toward true greatness in coal selling. Unfortunately, they stopped halfway to real achievement because they allowed their efforts to be confined mainly to one grade of coal. The Golbe Coal Co. could have become a real merchandising house if it had continued as it started. It is headed by a big man and a real merchant. It had the right policy. But, it fell short only because its head allowed himself to be tempted to scatter his fire by becoming interested in other things. And, so it goes through the list. Coal has some good merchants but no great ones. It needs great merchants.

The reason for this lack, as I believe, is that coal men as a class have never studied the sales end of their business to get at the essential facts about their merchandising program. For example, no one knows what amount of annual tonnage will support a private selling organization and what amount of annual tonnage will not. We do know that a man with ten million tons of annual output should have his own sales force. We know that a mine with 100,000 tons annually cannot afford it. But, where the dividing line is, we do not know. No studied effort has been made to find the facts. Still, that information should be gathered.

Again, it is obvious that a man who has less than 100,000 tons of coal a year to sell cannot travel over a big territory at his own expense. It would make his selling cost per ton too high. But, we have not the slightest idea how big is the territory over which a selling force can travel, economically, to sell an annual tonnage of a million or five million or even ten million tons. That information surely is necessary.

Further, it is assumed broadly—but without anything more than assumption behind it—that a man with an assortment of coals in his catalog can afford to travel a bigger territory than can the man who has the same tonnage of but one grade of coal. That may be true. Again, the likelihood is that it isn't true at all. A careful study of the facts might disclose that the man with the assortment of coals could make a bigger and surer selling record at less expense and at greater net profit to himself by the intensified cultivation of a much smaller selling zone.

It is along these lines that the trade needs to study if it is ever going to get that improvement in its selling efforts and that economy in selling which the trade must have. Seeing how much remains to be learned about the simplest things in coal merchandising, there is evident need for careful study and painstaking inquiry.

But, so long as we remain in the dark on these fundamentals, I cannot agree that the trade is ready to try any such dangerous experiment as to throw away its old selling system and to try a new one built on the old pattern.

So long as we remain in ignorance of correct coal merchandising the present mood of the trade to experiment on the selling question is closely akin to that of the child who tears up a toy to see what is inside it. It is both dangerous and destructive.

A Plague of Associations

By N. H. Seaburg

Boston, Mass.

During the past year and a half the coal industry has been swept with a plague, an epidemic of associations, every one the panacea for whatever exigency the constantly changing situation developed in the trade. Each little perplexity had its own particular mushroom panacea—a new association. The mere formation of an association seemed to allay the anxiety of those individuals interested, even if no cure was effected by it. It was felt that action had at least been taken, which was in itself some relief. Oftentimes the evil which had brought the association into existence disappeared or was eradicated long before the duly ordained committees had begun and, in the majority of cases, finished their investigations.

It is surprising to note how few the associations are that survived, if we disregard the blatant pretensions of the tail-ends of several which are desperately trying to maintain their identity. Indeed there are not many more of any real significance now than there were before the plague. But while this may be true, it is equally true that the trade as a whole has been greatly benefited by this epidemic of associations. It has brought home to every person engaged in the coal industry that greater and more substantial progress can be achieved by association and unity of interests than by individual action. And this lesson is well worth the price paid in hours and hours of valuable time spent in useless talk and vain efforts to remedy fleeting emergencies.

In consequence of the fact that the coal business is so broad in scope, competitive and antagonistic trade methods have been the rule. Any form of coöperation has always been looked upon with suspicion and disfavor. Perhaps of all business men in the country coal men are the most suspicious of their own kind—or have been until recently. "Mind your own business" has been the Koran. While this may be an excellent policy in personal affairs, the intricate civilization of today has outgrown it, particularly the business world. Interdependence is the fundamental support of society. We are today witnessing the greatest nations of the world struggling with this important problem in an effort to establish a League of Nations.

So, likewise, though in a lesser degree, the individual members in the coal industry are tentatively seeking to work out some program of associated effort that will be advantageous to all. The actions so far are somewhat half-hearted, due mainly to a lack of confidence, but this is to be expected. It will be overcome just as soon as the officers and members of sound associations realize that in order to be successful and efficient they must work just as hard and give just as much of themselves to the business of the association as they would and are doing in their own private undertakings.

Patronage is not worth a tittle if it is not backed up by something substantial. There has been too much of this kind of shirking. If the man and his ability and organization are not behind the name which he lends to the support of an association, then it may as well be withdrawn; it means nothing. Active work is what counts and brings results. Letting the other fellow do it is a human quality, but no healthy business has ever been founded on such a policy.

Also, there should be more concentration and less dabbling with every panacea that some well-meaning but unnecessarily alarmed person suggests. In union there is strength and efficiency, while "too many cooks" simply hamper the efforts of every one else. Strong and practical associations are the order of the day, but a plague of them should be avoided.

They Shiver in Paris for Lack of Coal

By Mark R. Lamb

In Paris, we are cold, but will be colder. The coal is of poor quality, anyway. Many slack heaps in Pennsylvania are coarser than the best grades delivered here. From this it will be seen why any kind of briquet is acceptable. It is a fact that large rectangular briquets are still made. They are stacked carefully each time they are moved. Then when used they must be broken by hand. The small oval briquet is in evidence, and when properly made is in great demand.

The heat is turned on in the hotel morning and evening for an hour, but now that the Peace Conference is on, we keep warm (with rage) wondering if the Germans are to be paid their war expenses. In Paris the men are happy enough, but one sees too many sad-eyed women in mourning. Who will pay *them?*

LIBERTY BONDS are being sold extensively throughout the country, as can be seen by the quotations on the various Stock Exchanges of the Nation. Unfortunately, there are few persons who are seeking to buy Liberty Bonds from the original purchasers, and many who are trying to sell. A decline has been inevitable under these circumstances; but as prices fall the bonds become increasingly desirable.

The present price for $100 Liberty Bonds paying 4¼ per cent. ran, on Feb. 27, between 94.14 and 95.54. The regular brokers having seats on the Stock Exchange will market these bonds for $1 a bond and $50 bonds for 50c. Thus a $100 bond will yield about $93 to the person who sells it. There is therefore no need for any man to sell his bonds at a large sacrifice.

The operator should buy the bonds from his employees at par or at the market price, or else buy them for a dollar or so below the market and sell them through a broker. The first plan is the best where the operator has the money. In case the workingman should be suspicious, the operator should post conspicuously the quoted rates as recorded in the public prints day by day.

Confidence would be increased if the operator did his utmost to argue the employee out of a purpose to sell his bonds when necessity did not so dictate, especially if the operator would post notices asking the men to hold on despite the short working week and ill health. It would be further increased if the operator would sell the bonds thus received as far as possible to local purchasers and at the price at which they come to his hand.

Financiers have at no time been surprised that bonds have been selling at a low figure. That was the experience in every foreign nation. Everyone knew that the reason for this fall was not the doubt that any nation would redeem its bonds, except in the case of Russia, but rather the fact that while patriotism will buy new bonds it will not always keep them; and it will not buy bonds that persons have bought and disposed of for good reasons, or for reasons not so adequate.

There has been a disposition among those who have never bought bonds before to say that the Government has not kept its word. This is, of course, an unreasonable argument. The Government only agrees to pay the bonds off when they become due. It might be truer to say that the bond holder who tries to sell has not kept his contract with the Government. The face of the bond shows that the purchaser lent the money to the Government for the time specified thereon. He now wants it before that time, and he it is who has not kept his word. If he has to sell his bond before the time, owing to difficulties in handling his finances and meeting his bills, then he is excused; but he must be contented to suffer the loss just as he has to do when surrendering his life insurance.

However, there is no need to rob the wage earner of three-quarters of his savings, as some sharks (not in the coal business, we trust) have done. The operator can handle the bonds and get the mine worker at least 92c. on the dollar, and thus show his good will to his employees and the sincerity of his patriotism.

The operator felt himself in duty bound to try every expedient to sell the bonds. He should be just as anxious now to uphold the national credit in the selling of them. Should, however, any man sell his bonds for liquor or other foolish thing, the less he gets for his bond perhaps the better it is for him. Yet such a man will be the first to declare that he has been unfairly dealt with. The hour to sell Liberty Bonds in order "to have a good time" is certainly not now, and it is doubtful if at any time it is a wise and good thing, or even a patriotic thing, to sell for self-entertainment a bond that represents a part of the national savings.

Operators should help to restore business by urging public improvements of a worthy character. When business hesitates, the municipal, state and national governments should bare their right arms.

Some Unrecognized Uses of the Wealthy

THE fare from Mt. Vernon to Coney Island, 29 miles, is a nickel. The public seems satisfied with that fare though the company is not. The fare on the railroad is 3c. a mile, or 87c. for 29 miles. The people are temporarily contented with that fare but would not consent to its being raised.

The public, then, is willing to pay 3c. a mile or less. Would it be willing, as a whole, to pay $1 or $1.50 a mile? It is unthinkable at present. A few wealthy men fortunately will put down their $100 to go 100 miles by aëroplane, and the art of flying will be developed, till the price falls to a level that workmen can meet.

So it has been with every development. Bicycles were manufactured for the well-to-do long before they became the recognized steed of the messenger boy. Automobiles were purchased for $20,000 for a long time before the Ford and the runabout took Guiseppe Sartor to the mine mouth. The rich are the pioneers. If there were none there could be no progress. In the wasteful economy of nature, the wasteful man is a necessary part, just as much as the wasteful water current and wasteful mountain breeze.

Nearly all developments come from the encouragement given them by the well-to-do. All improvements are tried first by them and on them, and then, when proved and standardized, they bring their benefits to those less fortunate. It is not a coincidence that Australia, that has no extremely wealthy people, has contributed little to the world. Admirable men and women.

their continent is a place apart. It cannot lead because of the dead level of the population. Art, invention, enterprise—all depend on wealth, though wealth without discretion and frugality is as unfortunate as poverty.

The luxuries of the rich soon become the necessities of the poor. Oranges, lemons, spices, bananas, were at one time luxuries. Who will so class them now? Their sale has stimulated industry, so that the rarity of the past has become the commonplace of the present.

Supply and demand regulate prices, and supply will fail as well as demand if the price is made so low that there is no profit in production. Goods on shelves may have to be given away if the demand ceases, but coal in the hill need not be disturbed if the price is inadequate.

A Clever Augur Can Find Whatever He Will

ARTHUR F. RICE, of the New York State Coal Merchants' Association, has prophesied that the price of coal (meaning doubtless domestic anthracite) is going to be greatly reduced. At first it would appear as if Mr. Rice believed that the price of coal charged by the producer was too high, in consideration of the costs of production, but later he makes it clear that his charge is that labor in the industry is overpaid, as also in other industries, and that materials purchased by the coal operator cost him too much.

Because of Mr. Rice's explanatory remarks it will not be necessary to take up the question from the point of view of the operator, whom he does not accuse. It will not be needful to repeat or prove what has already been repeated and proved, that 25 per cent. of the anthracite coal is sold for less than the mining cost and 60 per cent. is sold at such a figure as precludes a bond rate of revenue on the money invested. It is only required of us to show that the price of labor and materials is quite unlikely to decline.

The strength of the labor unions is such that they will not allow any reduction in wages. In fact not only the unions but most operators also are opposed to decreases in wage schedules. The general consensus of opinion among men in and out of the industry is against any scaling down in wage. For this reason it will not occur. It would not do the workingman any particular harm if only costs of living came down concurrently, as they ultimately would, but these costs would probably decline quite slowly and there would be an important exception in wheat, the price of which is regulated by law. But such a reduction would unsettle values and undermine confidence to such a degree that distress would be almost sure to intervene.

It is just as well that high-level wages remain stabilized. A few wage scales will be graduated upward till matters are equalized, and then prices will be fixed and business will move along without jarring or uncertainty. It is not likely that there will be any great scaling down of prices. A few things like anthracite will undoubtedy cost more. Bituminous coal will decline little if at all. Building costs will go up a little higher rather than down; wages have hardly reached their final adjustments among some of the trades involved. As for rents, they are sure to go up, though in many industries with low increases the renters will find it hard to pay such advances in rent. But till a further increase occurs building will not be remunerative, and no building program will go forward till immediate and adequate returns are certain.

A clever augur can find what he will, and some of the persons who happened not to be in a unionized trade or happen not to have to deal with unionized labor are not aware of the forces which now sustain the labor market. Mr. Rice's contention would have been incontestable 25 years ago, conceivable even 10 years ago; but it is impossible today. Let us cease advocating and prophesying what cannot happen, and pin our faith on facts, not on visions. Prices of materials will not decline, wages will remain just where they are, though outside the coal, munition, shipbuilding and a few more industries they may even rise. Knowing this there is no reason to delay buying, in fact anthracite should be bought now. It will never be as low in the future as it is at the present time.

Let the mine operator control the byproducts of his industry. Why should he restrict himself to mining and let others take his coal and make a fortune out of it? The operator should make byproduct coke, near coal, byproducts and power. He should not leave it to others to do this work and retain the profits.

Adoption of Larger Mechanical Units

IT IS a well-known principle in power-plant operation that the greatest economy is effected by the largest units. That this theory is generally recognized in the coal industry is well shown by an examination of statistics bearing on the subject. During the seven-year period 1902-1909, the total number of steam engines in the coal fields of the country increased from 11,142 to 19,318, or 73.4 per cent. During this same time the total horsepower increased 107.2 per cent. The average horsepower of all engines in use in 1909 has thus shown an increase of 50 per cent.

More recent figures for the Pennsylvania bituminous fields throw still more light on this subject. In 1910 there were 2880 steam engines in use, or one for each 52,000 tons of coal produced. Up to 1913 the total number of engines remained practically unchanged, but during the three succeeding years the number declined rapidly until in 1916 there were only 2313 steam engines in use in the Pennsylvania bituminous fields. The production of coal showed a consistent and fairly uniform increase over the entire six-year period, so that the tonnage produced per engine in 1916 amounted to 73,000, an increase of 40 per cent.

Progressive mine managers will follow this rapidly increasing development in mechanical efficiency closely. Manufacturers of machinery are devoting more attention to the requirements of the mines. Firms specializing on coal machinery of various descriptions are bringing some of the best brains in the country to bear on the subject, and the next decade will see an even more rapid development in the use of machinery in the coal fields, due to the increasing cost of labor.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

By no means let us fear discussing labor matters. The obvious may for some months, years or decades deceive the discussers, whether operators or mine workers, but time and study eventually lead to the truth, and maxims of the operator, long banned by the mine worker, become accepted and advanced by the latter, while the shibboleths of the mine worker, indignantly denied by the operator, finally meet his acceptance.

Let us, in labor matters, never despair of the coming of the light. It rises with education and discussion as surely as does the sun with cock crowing. A little learning is a dangerous thing; a few days of consideration may make a bolshevist, but several years of study cannot fail to make a conservative democrat. If it did not there would certainly be something wrong with conservative democracy and something to be commended in bolshevism. Truth always in the end justifies itself.

High Wages and Low Prices Conflict

Not in this present preface shall anything be said of that growing progress in economic orientation which has come to the operator almost without his realizing it. That which should be said is rather about the mine worker. He is beginning to see that wages are a function of prices, that prices are cost plus and that an orderly condition is not to be expected in business when that plus is dropped or converted into a minus. Listen to the anthracite mine worker's cry that no attempt shall be made to muckrake the coal industry and depress prices to such a low point as shall make it hard to pay fair wages. The workingman is beginning slowly to learn that the operator is the indispensable middleman who passes on as wages the greater part of what he receives as prices.

Five presidents of the United Mine Workers of America and their secretaries met in Harrisburg, Penn., on Feb. 19 and declared that they would fight the Glass bill in the House of Representatives. This bill provided for the appointment of a commission to investigate the prices of fuel and food and report recommendations for the lowering of those prices.

Labor Representative Opposes Price Inquiry

The mine workers fear that if fuel prices are lowered wages will go with them. This is what Representative David Fowler, of Lackawanna County, and a national organizer for the mine workers, had to say:

"Our present contract with the operators expires Apr. 20, 1920. Until that time there is no chance of a reduction in the wage scale, but we have to look ahead a little to the time for shaping a new contract. If this commission provided in the Glass bill recommends a decrease in fuel prices and it is placed in effect, there will be considerable difficulty in drawing up a contract that will suit the workers and the operators."

Time was when the mine workers disliked the operators so much that they tried to burn them like the proverbial candle at both ends. They fired them at one end with wages and at the other end they lighted the wick of lower prices, charging that the operator robbed the public by his exorbitant demands. They have learned better. In Illinois the mine workers have repeatedly threatened strikes on the luckless dolt of an operator who would cut prices which have been established as reasonable by the United States Fuel Administration. If these prices were fair during the war, they argue, they are still fair.

The disposition toward the day wage in western Canada recorded elsewhere in this department is quite interesting. It does not arise, however, from a proper consideration of economic principles. It seems to have its supporters in the laggards, the shiftless, the old men and the feeble.

Perhaps something might well be done for the two latter classes, when putting the more efficient day-labor principle into force. It should not be made hard for them to find a place in the scheme of things. However, is it not true that that place is not at the face but rather as watchmen, gatetenders, switchmen and what not? The older men and the feeble drift back, do they not, into the ranks of the day workers? After all, surely the problem presented by the feeble and the old does not throw a sufficient cloud on the validity of the day-work principle.

One cannot, nevertheless, advocate the total abandonment of piecework with its needful stimulus to production. A better plan would be a 50-50 arrangement, in which each man would get about half for his day labor and his presence at the mine for a full day and roughly half for his production in the course of that time. This economic arrangement would work for his good and for the good of the operator and public.

About 1500 Cape Breton mine workers are idle at the Florence and Sydney mines. The Nova Scotia Steel and Coal Co. has closed down No. 3 Florence mine as a protest, it is said, against the alleged interference in their operations on the part of the Dominion Coal Co. Whether the shutting down is a real protest born of resentment or only an action due to the inefficiency resulting from the Governmental decision to compel the Nova Scotia Steel and Coal Co. to surrender some of its lands to the Dominion Coal Co. is not clear. The Amalgamated Mine Workers of Nova Scotia at Glace Bay held a meeting Feb. 22 at which a resolution was passed calling on the provincial government to take what action is necessary to bring about the reëmployment of the men affected.

Alberta Miners Want Day-Wage System

Arguing that the present contract system or pay-by-what-you-achieve is not fair to the miner, the union mine workers of District No. 18 of the United Mine Workers of America in the western part of the Dominion of Canada declared that it produced wages excessively low. Asked what would be considered a fair wage, one delegate said $8 a day. The miners in Alberta are getting a little over one-half as much according to Delegate McRoberts, of Taber.

One of the men admitted at the recent 16th Annual Convention that some men were making good under the piecework contract, but he contended that the wage should be fixed on a per-diem basis. D. McNab, of Lethbridge, declared that some men in his district were working under contract and were making only from $2 to $2.50 a day.

It appeared to be the thought that in slack times the operators hired more men than necessity demanded and the result was that short time, short hours and slow run depleted the earnings of the contract workers and made it impossible to earn a good wage despite the fairness of the scale itself.

When Secretary Ed Browne was asked as to the ability of Alberta to start a system of its own, he replied that he was informed that each district had local autonomy in making contracts, but that the constitution of the union reserved to the international executive board the right of lending moral and financial aid when a strike is called. Ed Browne said he did not know of any district in America where the day-wage system was in operation.

An international organizer, Dave Irvine, stated that he had worked under the day-wage system at the mines of

the Stirling Coal Co. in Pennsylvania. On that occasion the operators took some of their largest mines and had them run to full capacity. They selected only the more efficient men, excluding all over 35 years of age. There was no compensation for working in wet or dangerous places. The feeling grew so strong that the manager was driven out of the district at the point of a gun. He said the day system would disrupt the union and declared that, under that method of payment, there would be ten times as many straw bosses as at present.

In the same convention a debate arose as to the condition of the bunkhouses which several delegates declared were of such character as to be unfitted for the housing of cattle. One man asserted that some had not been washed out for 18 months.

The *United Mine Workers' Journal* was described by one delegate as "more poisonous to the worker than any capitalist newspaper of Wall Street." The old wage scale in District No. 18 expires on Mar. 31, and the convention is for the purpose of determining what kind of contract will replace the old one.

Equal Time for Daymen and Miners

The local unions of the United Mine Workers of America, located within District No. 9, met in mass meeting at Kulpmont, Northumberland County, Pennsylvania, and decided, as stated last week, that they would be better off if only the United States Government could be induced to operate the mines. They want full-time operation and believe that it could be arranged if the Federal authorities had control and ownership. Irregular work gives them only inadequate pay, while food and clothing remain at the same high prices. The mines are working only about three days a week.

Some problems, which have lain low while work was steady and pressing, now come again to the fore. Miners where there are good haulage facilities often work on idle days preparing coal, so that on the next working day there will be no difficulty in producing large individual tonnage. At some mines there are men who earn as much with half-time operation of the mines as if the mines worked every day.

The mine workers meeting at Kulpmont attacked this practice of allowing miners to work every day while the day workers only work, say, three days a week. In Indiana and in some parts of the Middle West no work is done on what are known as "idle days," and miners are fined who fill cars when the mine is officially idle.

In parts of central Pennsylvania drivers themselves prepare coal on idle days. They are sometimes allowed to place a few cars at quitting time or on the idle day. These they themselves load with coal in chambers that would otherwise not be working. These practices are so general that they explain in part why, with steady work, the production last year was not so great as would have been obtained if the same per diem production had been maintained with full operation as was obtained with broken time.

The mine workers also passed a resolution directing miners not to do company work as they had been in the habit of doing during the war. Miners are not asked to do day work unless some day worker is idle. Refusal to do the work does not help the day worker but does cripple the mines and prevents the miner from getting the fullest time that conditions warrant, for a dayman short will delay the work of many miners.

Leaders in the Right on Bolshevism

The first open evidences of bolshevism among the United Mine Workers in West Virginia was exhibited on Friday, Feb. 14, when about 500 or 1000 miners in attendance at a special convention of district No. 17 paraded the principal streets of Charleston, winding up their parade in front of the capitol, from the portico of which a fiery speech was made by "Mother Jones." The demonstration staged was in the nature of a protest against the bill which prohibits anyone from displaying or having in his or her possession a red flag or any other kind of a flag except that of the United States, or of a nation with which the United States is not at war. It was also a protest against the enactment of any kind of law replacing the national guard by a police force in the work of providing for local order.

The miners' convention was called for the sole purpose of protesting against these two bills, and it lasted throughout the week, during which time many bolshevik addresses were made. Several delegations called on Governor Cornwell, insisting that he agree to veto both bills against which the miners were protesting when these bills came to him for approval; but the governor stood his ground, pointing out that he had recommended both measures in his message and that some form of state police protection was necessary.

The climax came, however, when the miners' convention passed a resolution condemning the representatives of organized labor in the House of Delegates for voting for the anti-red flag bill, Mother Jones heaping vitriolic abuse on the labor representatives as well as on the whole legislature in her speech from the front of the capitol. The labor representatives, in a statement inserted in the record of the House, while defending their course pretty plainly insinuated that the miners were on a par with the Industrial Workers of the World and the Bolsheviki. The statement follows:

"Organized labor is not afraid to trust the people. The American Federation of Labor performed a great task of patriotic duty when it set its face hard against I. W. W.-ism, bolshevism and those forces of destruction which believe in 'sabotage' or direct action, and which seek to destroy the confidence of the people in the Government, and would overthrow it if they had the power.

"We rejoice that the Administration at Washington is deporting these advocates of terrorism from the country. These forces are constantly working to misdirect the labor movement. The man or woman who marches under the red flag is in full sympathy with the progress of the terrorists.

"It is our deliberate judgment that we would have made a mistake if we had opposed House Bill 104. We would have placed organized labor in an unhappy light, and, by failing to support the measure, would have reflected on both your loyalty and intelligence."

Illinois Mines Are Working Slowly

Harry Fishwick, vice president of the United Mine Workers in Illinois says that there are 90,000 coal-mine workers in that state working less than half time. About 600 mines are running in a haphazard way. Some of them are operated only three days a week. Some mines are only working one day in seven, and the average time is only 2½ days a week. With our present way of looking at affairs such men cannot be said to be employed.

Coal operators say that owing to conditions in the market there is practically no demand for coal the state over, the amount still remaining in storage precluding any further purchases. The industrial unrest and the uncertainty as to future demand are also factors in the present dullness. However, Fishwick is optimistic over the general outlook.

The discontent is being fanned, not only by the slow running of producing mines, but by reason of the complete closing down during the winter of the mines started to supply the large war-time consumption. New mines were opened, old and abandoned mines were reopened and many of these were too new or too old or too poorly planned and managed to be profitable with declining prices. They are closed down already or will be closing during the course of the present year. With 20,000 more miners nominally at work than before the war started, readjustment of conditions is not without its difficulties.

Tonnage has decreased since the armistice is signed. In October when hostilities ceased (Oct. 11) the Illinois output was 8,286,000 tons, in November 6,286,000, in December around 6,000,000 tons. January and February are expected to show even greater decreases in coal output.

Leave a Little for Other Workers

A few mine workers have been expecting a further wage increase. There are unfortunately only just so many bites in the apple of the World's Production, so let us refrain from even the thought that we have the right to insist on taking two bites. The apple of the World's Production in 1919 is going to be small. Everywhere work has been lacking in steadiness; everywhere there has been ill health. There will be less than usual to divide, so the industry must not look for larger wages, but rest content with those it has. In this way every mine worker will get his share of the World's Production in 1919. Too bad the apple seems likely to be small, but we can look for larger apples when business gets adjusted to the present high wage scale.

DISCUSSION BY READERS

Gravity-Plane Haulage

Letter No. 1—I have read with a great deal of interest the question of using a gravity-plane haulage, presented in the inquiry, *Coal Age*, Jan. 2, p. 32; and, while I agree with the formula that was shown in the reply to this question, I would like to add a few comments designed to show further the impracticability of attempting to operate the proposed incline as a gravity plane for hauling trips of 25 cars, as stated in the inquiry.

Of course, the matter of laying out a gravity plane, so that the loaded cars descending the plane will pull the empties back up the grade, must be analyzed carefully and the number of cars that it is possible to haul in a trip determined by a calculation based on the various data given or involved in the question. It is the only way that such a problem can be successfully solved and its practicability determined.

However, let me suggest viewing the proposition from another angle and consider the case from the viewpoint of the descending load. Since the empty cars are said to weigh 1500 lb. and have a capacity of 2600 lb. of coal, each, the total weight of a trip of 25 loaded cars would be $25(1500 + 2600) = 102{,}500$ lb., or nearly 52 tons. On a grade of 20 per cent., I calculate that the strain on the haulage rope would be about 18 tons, which would require a $1\frac{5}{8}$-in. steel rope.

But, it is necessary to consider, also, the weight of the rope, which would be about 6 lb. per ft. This would increase the load on the rope considerably and would necessitate using a $1\frac{7}{8}$-in. rope, instead of that previously mentioned. Such a rope would cost over $1 per ft., which would make this proposed method of transporting the coal from the tipple to the tracks for shipment expensive. At the same time, the incline would have to be so arranged as to give a proper landing place, both at the top and the bottom of the plane, sufficient to accommodate 25 cars in a straight line.

In my experience, I have never seen an incline operated by gravity on as large a scale as this, and I am very doubtful if it can be done. Instead of the proposed incline, let me suggest the advisability of installing an aerial tramway for lowering this coal from the tipple to the point of shipment. The use of such a tramway would insure a large daily capacity.

St. Louis, Mo. WIRE ROPE.

[We quite agree with the suggestion of an aerial tramway, which this correspondent has offered as a substitute for the proposed gravity incline mentioned in the inquiry to which he has referred. It was shown in our reply to that inquiry that the conditions would only permit the lowering of a trip of five cars at a time; and we stated that it was practically impossible to handle trips of 25 cars of the size given, on such an incline.

However, our correspondent, in his calculation of the size of rope required to hold a descending loaded trip of 25 cars having a total weight of 102,500 lb., is somewhat in error. The gravity pull of this loaded trip, descending a 20 per cent. grade, and assuming a track resistance of 20 lb. per ton, is calculated by the formula

$$S = W\left(\sin a - \frac{\cos a}{100}\right)$$

In this formula S = the load on the rope (lb.); W = the total weight of a loaded trip (lb.); a = the angle of inclination of the incline, or the grade angle. For a 20 per cent. grade, based on horizontal measurement, the grade angle is 11° 19′; and $\sin a = 0.19623$; $\cos a = 0.98056$. Hence substituting these and the given values in this formula, we find, for the load on the rope when a loaded trip of 25 cars is at the top of the incline

$$S = \frac{102{,}500}{2000}\left(0.19623 - \frac{0.98056}{100}\right) = 9.5 \text{ tons.}$$

The size of rope required for this safe working load is a $1\frac{1}{4}$ cast-steel, 6-strand, 7-wire haulage rope, which will carry a safe working load of 9.6 tons and weighs 2.45 lb. per ft. The weight of this rope for a length of 5500 ft. is, therefore, $5500 \times 2.45 = 13{,}475$ lb. The gravity pull due to this rope resting on the rope rollers, on the incline, may be taken as adding $1\frac{1}{4}$ tons when the loaded trip is at or near the foot of the incline, which would make the total load on the rope about $10\frac{3}{4}$ tons, and would require increasing the diameter of the rope to $1\frac{3}{8}$ in., instead of $1\frac{7}{8}$ in., as estimated by the correspondent.—EDITOR.]

Coal, Railroads and the Government

Letter No. 2—Referring to the probable five-year extension of government control of railroads, to which attention is drawn in the Foreword, in *Coal Age*, Jan. 23, allow me to say many seem to think that a decided benefit will result under the guiding hand of the Government. It is quite generally thought that there will be a more equitable distribution of cars and markets, in the different coal-producing districts; and that strikes and lockouts by reason of labor difficulties will be prevented, and less frequent shutdowns occur by reason of lack of car supply. It is even thought that price fixing will make the profits of coal operators more uniform when the Government has full control of the situation.

It is argued that the unlimited ability of the Government to supply what capital is needed for the building of tracks, bridges, culverts, etc., to reach isolated mines, will greatly assist the development of properties lying in such districts. This, of course, particularly applies to mountainous regions, where private capital has been inadequate for such development.

In some cases, where it has happened that the managements of competing mines engaged in the development of adjoining properties, have labored under the unnecessary expense of building two lines to reach their properties, the advantage will be gained that, under a single

administration, a single track only will be required. This condition will prove a benefit under government control.

On the other hand, however, government control of railroads, in its effect on the transportation of coal, may be found to possess some disadvantages. The appointment of a single man clothed with power to direct affairs may be assumed to be not without the danger of prejudice developing in favor of one locality to the detriment of another. It can hardly be expected that the same interest will be shown in different developments as under private ownership and control.

Again, the large army of railroad employees, when working for the Government, may not manifest the same interest as they would show if working for a single corporation, and the efficiency of the system may thus be lessened. Permit me, here, to cite an instance that came to light, in my conversation with a man who had worked, last winter, to clear the tracks of snow, on railroads owned by the Canadian government.

Railroad traffic was completely blockaded between the largest cities in Canada. The force employed to clear the tracks were reported as "working full time," which they were not. In describing the situation, this man said, "What does it matter whether we work or not, when the government is good for our money?" Such may be the results in the States when the railroads are under government control. C. McMANIMAN.

Rawdon, Quebec, Canada.

Ventilating Power Excessive

Letter No. 2—I was both amused and astonished, in reading the statement of P. A. Grady, in *Coal Age*, Jan. 2, p. 27, to the effect that a large operation in his state (West Virginia) found that their ventilating power was costing 7c. per ton of coal mined, which was afterward reduced to 1c. a ton. This was an extraordinary occurrence and raises the question, in one's mind, as to what was the cause. It is my belief that the same conditions exist in almost every mine where the management does not possess a knowledge of the chief principles governing mine ventilation.

Too often it happens that little heed is given to the power consumed in the ventilation of a mine. The aircourses are not examined and cleaned up and the distance that the air must travel shortened as much as possible. Seldom is any attention given to a close examination of the many indirect causes by which the cost of production is greatly increased. But, when word goes out that the cost of operation must be reduced, the attention of the mine officials is commonly given to other matters, while these hidden causes are overlooked entirely.

What is necessary to bring about a more intelligent understanding of the causes that increase the cost of production is the installation of meters that will show the power consumed in the different operations of the mine. There should be a more general use of such meters, water gages, and other instruments to ascertain the exact condition. It is staggering to think that the installation of a single meter, in the case mentioned, brought to light the fact that a saving of 6c., per ton per day, could be effected. In other words, assuming the output of that mine was 1000 tons, it was found possible to save $60 a day, or from $15,000 to $20,000 a year, in ventilation alone.

Does not this fact impress the thought that there is great need of superintendents with technical education? Yet, how true it is that coal operators often regard such men as expensive luxuries that they cannot afford. But, where such men have been employed they have, at times, laid the foundation of future efficiency that some other fellow, less competent than themselves, has received the credit for accomplishing, because the management cut out the higher-price man just when he was about to reap the reward of his labors.

For a time, a great improvement is observed and the new man is credited with what was the other man's dues; but the later falling off of the output shows the management their mistake. I sometimes think that if more superintendents owned a little stock in the mine in their charge, greater efficiency and economy would result. W. H. LUXTON.

Linton, Ind.

Cost of Upkeep of Mine Cars

Letter No. 1—I was interested in reading the inquiry in *Coal Age*, Nov. 14, p. 918, relative to comparative systems of costs in repairing mine cars. The inquirer requested that readers of *Coal Age* having available records of such costs of upkeep of either plain- or roller-bearing cars should be willing to present them for discussion.

It was hoped that the attention thus drawn to this subject would help to show how the costs of repairs can be much reduced. That there has not been more of a response to this request seems to indicate that the matter of systematic repairs of mine cars is one that has not received the attention it deserves. As has been suggested, these repairs are too often made in a "haphazard or makeshift fashion."

CONSIDERATIONS THAT WILL REDUCE COST

While I have no figures to present, permit me to offer a few suggestions regarding the repair of mine cars. The first consideration is to give proper attention to the weakest parts of the car and those that succumb more easily to wear and tear in use. The type of car employed in any particular mine should be adapted to the conditions of the service. In mines where there are heavy grades—and there are many such mines—the cars should be equipped with a suitable brake, if it is desired to minimize the cost of repairs. The absence of good brakes on mine cars is the cause of more runaways and wrecks, resulting in bent axles, broken cars and other injuries that require the car being sent to the shop for repairs.

It will, of course, frequently happen that the poor judgment of a miner, or his negligence in not seeing that the car set in his place is out of danger when a blast is fired, will result in the end of the car being stove in by the blast. At other times, a car may be flattened out or otherwise injured by a heavy fall of rock in a place. Such accidents, however, are less frequently the cause of repairs being needed, than the neglect to equip the cars with good brakes. At least, that is my experience.

Another item that is the cause of the need of frequent repairs is the wear of wheels and boxes or bearings. Of course, this wear will take place sooner or later; but wheels and bearings will last much longer if they are properly lubricated or oiled. Also, the cars will need to be sent to the shop less often if worn wheels are not used and the bearings are kept in good condition. The car will run much more smoothly and be subject to less wear and tear when that is the case.

Prompt Repairs and Close Inspection Needed

Attention must also be given to other parts that are subject to the severe strain of service, such as drawbars, couplings and bumpers. It would seem unnecessary to mention, in this connection, that the roadbed and track should be maintained in good condition, if the cost of car repairs is to be kept low.

In closing, let me say that every car should be carefully inspected on the tipple, before it is sent back into the mine. It will often be found that a bolt is needed, or some similar slight repair is wanted and which can be made on the tipple without sending the car to the shop. Prompt attention to these seemingly simple requirements will go far toward avoiding more costly repairs in the future.

Of course, for the more serious repairs, it will pay better to shop the car, which should always be done before the latter is sent back into the mine, to be further weakened and cause a possible wreck. Car repairmen, foremen, and tipplemen should coöperate in the careful inspection of all cars, and no requirements, however simple, should be neglected, but should be attended to at once. Car Repairman.

Thomas, W. Va.

Iron vs. Wood Mine Cars

Letter No. 8—Referring to the discussion of the question of the relative merits of iron and wood mine cars, permit me to say that my own personal experience makes me prefer the wood car, which I believe is much better, considered from the standpoint of repairs. Few mines are equipped with appliances for making repairs on steel cars that have been damaged in the mine. On the other hand, nearly every mine in the country is equipped for making the necessary repairs to wood cars.

The composite car, part wood and part iron, while possessing much of the advantage in regard to lightness and being less rigid than the steel car, still presents much of the difficulty of the latter type, in respect to the repairs needed after the car has been in a wreck. Wherever it is possible to provide some simple and practical method for repairing the composite car, it is my opinion that this would be the most satisfactory type to employ in coal-mining practice. This is particularly true in mines where there is less danger of the cars being rusted and corroded by the acid mine water.

Where conditions are so variable as in coal mining, there is always bound to be much difference of opinion in respect to the merits and demerits of two types of equipment, such as are here presented. From the letters thus far submitted, however, nearly everyone has advocated the use of the wood car, and it would be interesting to hear from a strong advocate of either the steel or the composite car, and to observe what arguments he would present to support his view.

In his letter, *Coal Age*, Jan. 16, p. 157, "Progressive" asked for the type of wheel that has the longest life. In this regard, let me submit my conclusions, drawn from experience with different types of wheels, of which there are a large number on the market that merit consideration in respect to their material, chill and strength. I have tried practically all of these types.

In my estimation, the wheel that will give the best mine service is a good flexible, roller-bearing wheel that is so designed that the bearing will have a definite inclosure in which to work. I mean by this that the design of the wheel should be such that the bearing will at all times be free from end thrust and end wear, which will have a tendency to keep the lubricant well distributed in the bearing.

Practical Design of Roller-Bearing Wheels

The design of the wheel should also be such that it will be easy to get off without requiring the services of three men and a boy for that work. Some wheels require the knowledge of a man who can open a safe without knowing the combination, before he can get the wheel off the car. The resulting loss of time would eliminate such a wheel from mine use.

Another feature that appeals to me, in the construction of a mine-car wheel, is a cage for the rollers to work in. It has always been my experience that when the rollers are put in loose, they fall out in the dirt, the moment the wheel is taken off. It is then a pretty hard matter for a man to get them all back where they came from, to say nothing of the work of cleaning off the dirt and grit that adheres to the rollers.

Several of the manufacturers of this type of equipment make wheels that, with proper care, will last from seven to ten years, in mine service. Let me say that my idea of a good wheel is one that will give satisfactory service for this length of time and be easy to take off and put on, while at the same time being economical in respect to lubrication.

———, Ill. Richard W. Harris.

Letter No. 9—Regarding the relative utility of these two types of cars, in coal-mining practice, permit me to submit the following suggestions as the result of my own observations and experience.

Before a final selection of any mining equipment is made, careful consideration should be given to the many aspects that bear on the economical and successful working of the apparatus in question. In respect to mine cars, the shape, dimensions and capacity of the cars must be carefully determined, in conformity with the desired output of the mine and the conditions relating to length of haul and style of equipment. The kind of material entering the car must be selected with respect to the service required in the mine and the means at hand for repairing the cars when damaged.

In bituminous mining practice, in my estimation, a cheap and at the same time serviceable car is one made entirely of wood. The bottom planks are 3 in. thick, side planks, 1½ in. thick and the doors and back ends, 2 in. thick. The floor and side planks are bolted to properly bent car irons, which serve as stays to keep the car body from spreading.

Wood cars of this type are easily repaired and require no skilled labor for that purpose. The work is all done in an ordinarily equipped mine-car shop. The necessary iron stays, wheels and axles are readily obtained from manufacturers dealing in such material. The particular advantage gained in the use of wood cars is the ease with which repairs can be made when a wreck occurs in the mine. It will then require but a few days to put the cars in shape for use again. This is not the case where iron or steel cars are in use.

When a wreck occurs in a mine using iron cars it will often take a day or two to clear the track so that haulage can be resumed on that entry. Moreover, after the wreck is cleared, special equipment is required to straighten the bent cars and make them again ready for service. Another disadvantage in the use of iron cars is the corrosion that takes place by reason of the iron being exposed to the moist air and acid water of a coal mine.

The Composite Car in Anthracite Mines

In anthracite-mining practice, a part wood and part iron car is often used with economy and satisfaction where the cars are hauled in long trips over great distances daily. The bed frame of this type of car should be made of oak lumber. The end-sills and cross-sills must be tenoned or mortised into the side-sills and the entire frame held together with the tie bars. The side-sills are made to project at each end of the car so as to form bumpers. These are supported by an auxiliary block bolted to the frame and further protected with sheet iron to prevent the ends of the timber being split.

The bottoms and sides of this car are formed of heavy sheet iron to provide for the great wear due to the sharp hard coal, which is often loaded from a chute from 1 to 3 ft. above the car. This style of car being in parts is cheaply and easily repaired when damaged.

Sugarloaf, Penn. Joseph Lawrence.

Drawing Pillars in Machine Mining

Letter No. 7—My attention having been called, only recently, to the inquiry that appeared in *Coal Age*, Jan. 2, p. 32, regarding the drawing back of pillars by machines, allow me to give a brief outline of the method that has worked out very favorably in our mine, where the pillars are drawn back with electric chain machines, in a seam of coal varying from 5 to 8 ft. in thickness. The plan is as follows:

Assuming that the nature of the top and bottom presents conditions that are favorable to the use of machines, and that the rooms are driven on, say 50-ft. centers, giving a good width of pillar sufficient for the support of the roof when retreating, the first step is to drive a crosscut through the pillar, at the face of a room that has reached the limit.

Having cut through the pillar at the face, the machine is moved back and a new cut started in the pillar, leaving a stump of not less than 8 ft. in thickness, between this cut and the last one. This is done for the protection of the machine and the men while making the cut.

When this second cut has been carried through the pillar, the machine is brought around and the protecting stump is cut out, except two small stumps, one at each end, which are left for the protection of the cutter and must be taken out later with picks.

The same process is followed continuously, by making successive cuts through the pillar and removing the stump as each cut is finished, in the manner I have described, until the entire pillar is removed back to the entry stump. When this plan is given a fair trial, I believe it will prove successful under favorable conditions for machine work. Mine Foreman.

Homer City, Penn.

Letter No. 8—I regret that the inquirer, in this case, has not stated the thickness of the pillars, the hardness of the coal, or the nature of the bottom, all of which have an important bearing on the question of drawing back the pillars. One may assume, however, a two-thirds extraction of the coal, which is a common rule in practice; and this would indicate that the rooms were driven on about 40-ft. centers, which would make the room pillars 13 ft. thick.

Now, taking the average weight of material forming the overburden as 160 lb. per cu.ft., the roof pressure due to 200 ft. of cover is $200 \times 160 = 32{,}000$ lb. per sq.ft. This would mean that the pressure on a 13-ft. pillar, with rooms driven 27 ft. wide, would be $32{,}000 \times 40 \div 13 = 98{,}460$ lb., or nearly 50 tons per sq.ft.

Whether the pillars will be able to withstand this pressure will depend chiefly on the crushing strength of the coal, which varies widely with different coals and in different localities. In order to reduce this pressure, there must be a greater width of pillar as compared with the width of the rooms. Also, it will be difficult to draw back the pillar with machines where the bottom is soft, as the heaving of the bottom under the increasing pressure of the pillars would make it impossible to use the machines.

Assuming, however, that the conditions are such as to permit the use of machines, my plan would be to cut through each pillar 10 ft. wide, leaving 10 ft. of solid coal to be mined out with the pick. This work must be done regularly in order to give a good line of fracture. No. 1 pillar should be drawn by cutting through from No. 2 room. The first cut in No. 2 pillar should be made as soon as the second cut in No. 1 is completed.

The roof must be well timbered before starting any cuts in the pillars. When the stump 10 ft. in width has been removed with picks and the timbers drawn, if the roof fails to break, a fall should be started by placing one or more shots in the roof, a short distance back in the gob. It is important to do this in order to prevent the roof from breaking off at the pillar, which it may do later unless a fall is started in the manner I have mentioned. C. McManiman.

Rawdon, Quebec, Canada.

Efficiency in Firebossing

Letter No. 7—A few years ago, I was talking with a foreman who had given up his position, owing to a nervous breakdown caused by overwork. On recovering, he was content to accept a position as assistant foreman. In speaking of this backward step, he said, "Never will I again take a position as foreman where there are a lot

of firebosses who take no interest in any work other than their own. In my last place, I had no help; the firebosses were of no assistance to me and I was forced to keep plugging away, until I broke down under the strain. If I were to assume the responsibilities of foreman again, I would be very particular whom I selected as my lieutenants."

Helpfulness of Firebosses Who Coöperate

Many a foreman has had a similar experience and has succumbed to the arduous duties of his position, because of the lack of helpfulness and coöperation, on the part of the firebosses. Many firebosses are content to think that they have done their whole duty when their morning examination is finished, believing that nothing else is expected of them. But, give me the man who makes his rounds with his eyes open and is willing to cooperate with his foreman in every particular that will assist in making the day's run a success.

Such a fireboss can tell from his observation what coal is loaded and where empties are needed; what places should be timbered or roads cleared of falls and give other information that will assist the foreman in starting work in the mine where it is most needed. Such a one is constantly looking ahead and lending every assistance to keep the wheels turning in the mine.

Many a person who holds a certificate of qualification to act as fireboss has found, on assuming the duties of that position, that he must possess something more than his certificate, in order to successfully carry on the work required of him. The manner in which he performs his duties determines his efficiency as a fireboss. Much will depend on his training. The most successful fireboss is, often, a man who has had several years' experience as a bratticeman, which has taught him the most efficient means of handling gas accumulated in the workings, and what precautions it is necessary to take to insure the safety of the men employed in the mine.

During the last 20 years, I have watched men taken from other occupations, to assume the duties and responsibilities of firebossing, for which their previous training has ill-adapted them. In answer to some of the simplest questions relating to the work they were about to undertake, their words and manner betrayed their ignorance. In regard to some of the conditions they were liable to encounter, they showed that they had not even given the matter a thought.

Intelligent Firebossing Requires Constant Study

The position of fireboss is one in which a man is exposed to danger at all times. He must perform his work conscientiously and fearlessly, both for the welfare of the men in his charge and his employers. The intelligent fireboss will thoroughly familiarize himself with all the features of the safety lamp he uses to make his examination of the mine. He will study the mine map to acquaint himself fully with the requirements in respect to the ventilation of the present workings and the future development of the mine. He must know the requirements of the law and study to make the work conform to its provisions in every respect.

The fireboss who is alert to his opportunities at all times will devote his spare moments to the careful study of questions concerning the work in his charge. He will study these questions both from a practical and a theoretical standpoint. The district to which he has been assigned may be a gassy one, requiring the most careful attention in respect to ventilation and development. The results will show whether or not the man is qualified for the work and the manner of his performance will quickly show his ability to make a good lieutenant, who will coöperate with his foreman.

Another feature, in good firebossing, is a man's ability to handle his men successfully. He must make them understand that he is interested in their welfare. On finding a dangerous condition in a man's place, he must not pounce on the fellow as a catamount would pounce on its prey; but he must take the fellow aside, point out the danger and get him to realize what it means and what he must do to avoid it.

By civil treatment of men as human beings, a fireboss can do more to gain their confidence and have them respect his authority than by any other means. He will thus be able to secure their hearty coöperation and cause them to feel that a place is really dangerous "if the fireboss says so." All this can be accomplished with tact and good judgment, without catering to one and another; and by settling little troubles that arise, without sending for the foreman, which will cause the latter to sit up and take notice that he has a lieutenant that understands his business.

Firebosses the Foreman's Lieutenants

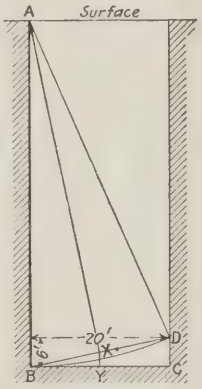
Let me say that any mine foreman who thinks he can run a mine properly without the aid of his lieutenants has an exalted opinion of himself. No wise foreman will bemean his fireboss by sending him to perform work described in the letter of F. G. J., *Coal Age*, Dec. 19, p. 1133, as "carrying bricks." To underestimate the capabilities of a good fireboss shows lack of gumption on the part of the foreman. This would seem to be the case in the citation given in the letter to which I have just referred.

In closing, I will say that a good fireboss is a man who has the initiative to act promptly when an occasion may require. It is that characteristic that will be of great assistance to the foreman. For instance: The morning round being made and the mine reported "O. K.," the men start work loading and blasting coal. A little later, an unfortunate shot has ignited a feeder, and the flame has crept back under the loose coal.

Let us say the miner becomes excited, as the foreman is in a distant part of the mine and can lend no help. But, the alert fireboss is quickly on the scene, and, summoning help, has the loose coal removed and the flame extinguished, thus proving himself a good lieutenant and averting a danger that would have proved serious but for his timely and efficient work.

Again, in the absence of the foreman, in that particular part of the mine, a heavy fall blocks the main road in a certain section. The capable fireboss, once more, shows his efficiency by taking charge and setting men to work to remove the fall and clear the track. Numerous other instances could be cited to show the efficiency of the man with initiative. Suffice it to say that the foreman who is surrounded with such firebosses can go home at night with his mind at ease. He will seldom be the subject of a nervous breakdown because of the strain of continuous overwork.

Kingston, Penn. Lewis R. Thomas.



INQUIRIES OF GENERAL INTEREST

Calculating Depth of Shaft

A few days ago my foreman gave me a problem to calculate. As it has been a number of years since I studied trigonometry, I want to ask for the simplest method of solution. He stated that a plumb bob, hung from the top of a shaft that was 20 ft. wide, just reached the bottom, at one side; but when the bob was pulled to the opposite side of the shaft it raised 6 ft. off the bottom. I was asked to calculate the depth of the shaft, from this data. My method by trigonometry, gives this depth as 36 ft. 4 in. Is that correct, and is there a simpler method? STUDENT.

Carlinville, Ill.

It is not necessary to employ trigonometry in this case. The simplest solution is by means of two similar triangles. For example, referring to the accompanying figure, $AB = x$, the depth of the shaft; $BC = 20$ ft., its width; and $CD = 6$ ft., the height the bob rises from the floor when it is pulled to the opposite side of the shaft. Now, the triangle ABD being isosceles, AX, drawn perpendicular to BD bisects the latter and XY is one-half CD, or 3 ft.; and BY is one-half BC, or 10 ft. Then $BX = \sqrt{3^2 + 10^2} = \sqrt{109} = 10.44$ ft.

SECTION THROUGH SHAFT

But, the two right triangles ABX and BXY are similar, having their respective angles equal. Hence:

$$AB : BX :: BX : XY; \quad \text{or } AB = \frac{BX^2}{XY}$$

Then, substituting the given values in this formula, we find for the depth of the shaft,

$$x = \frac{10.44^2}{3} = \frac{109}{3} = 36\tfrac{1}{3}\ ft.$$

The depth of the shaft is therefore 36 ft. 4 in.

Payment for Yardage and Deadwork

I am interested in learning what is the usual practice of coal operators in the payment of their miners for yardage and various kinds of deadwork common to the mining of coal.

At present, I have in mind a coal seam averaging 3½ or 4 ft. in thickness and overlaid with from 4 to 10 in. of slate, above which is 6 or 8 in. of coal. The slate binder and the thin coal above it both come down easily without much shooting and are thrown back into the gob. At times, the rock overlying the wild coal comes down also and must then be handled and stowed in the waste.

Any information that *Coal Age* or its readers can give me, on the general subject of what should be paid for yardage and by what method these prices are determined, will be greatly appreciated. G. STERN.

Frostburg, Md.

The prices paid for yardage and deadwork, in coal mining, are necessarily quite variable, owing to the wide difference in conditions in mines. In any case, the price paid should be based on an agreed valuation of labor and a fair estimation of what would constitute a day's work. It is not to be expected that these matters can be settled and a satisfactory conclusion reached without much prolonged discussion, as the opinions of both employer and employee are more or less biased in favor of their own interests.

In many coal-mining districts, operators have entered into an agreement with their men and the prices to be paid for different classes of work have been adjusted to conform to the known conditions in the mine. In most cases, such an agreement or contract specifies in considerable detail the nature and extent of the work, which is to be performed at a fixed rate or scale of wages and for a specified period. This is the usual case in a union mine; but even where such agreements exist there are many instances of disagreement when the matter in dispute must be arbitrated.

Perhaps, there is no greater difficulty that arises between an employer and his employees than that of fixing a satisfactory price for piecework and yardage. Formerly, all work of that description was commonly done on company time, the miner being paid according to the regular wage scale. But, that did not satisfy him always, as he claimed he could make more money digging coal than by taking down top, lifting bottom or cleaning up roof falls.

Much will depend on the tact and diplomacy of the mine foreman in adjusting a miner's claim for extra time. Such claims are frequently made when a man's place meets a boulder or develops a small roll that thins out the coal. Frequently, a foreman will allow the miner working such a place a keg of powder to compensate him for his extra labor and loss of coal, although every practical miner knows that these troubles are common occurrences in the mining of coal; in other words, they are a part of the game.

By way of summing up this reply, let it be said that, in all cases, the determination of the price that should be paid for labor must be based on an average worker's earning power when performing the task in question. In estimating yardage when driving a 10-ft. heading in a 4-ft. seam, where miners load, an average of 10 tons, at 90c. a ton, thereby earning $10 \times 0.90 =$ $9.00 a day, assuming the heading is driven 1½ yd., the entryman loads, say 7 tons of coal for which he is paid $7 \times 0.90 =$ $6.30, and to equalize his earning power he should receive, as yardage, for handling the refuse over the coal, $(9.00 - 6.30) \div 1\frac{1}{2} =$ $1.80 a yard.

EXAMINATION QUESTIONS

Alabama First-Class Examination, Birmingham, Jan. 20-23, 1919

(*Selected Questions*)

Ques.—A large percentage of mine accidents are caused by miners persisting in loading coal where the roof is unsafe. What rule would you adopt to prevent this condition and reduce the number of accidents?

Ans.—The rule should be adopted making it the duty of every miner to examine carefully the condition of his working place when he first enters the same and before doing anything else. He must observe any marks or danger signs that may have been placed by the fireboss when making his morning examination. If any posts have been knocked out by a blast or a loose piece of top or loose coal is found, it must be made the duty of the miner to reset such posts and stand any other timber that may be required to secure the roof or coal. If loose top or coal is to be taken down, it must be done at once before the miner proceeds to load his coal or do other work.

However, the average coal miner is prone to disregard any rules made for his safety and it becomes necessary, in order to prevent accidents from falls of roof and coal in the working places, to require the frequent and close inspection of all places, by a competent safety inspector or fireboss, while the men are at work. If the fireboss finds a working place unsafe for work when making his morning examination it is his duty not only to place the customary danger signals at all entrances to the place, but also to take the man's check from the board, which will notify the man that he is not to proceed to his work till his place is made safe. All such checks are given at once to the mine foreman, whose duty it is to see that the places of those miners are put in condition for work. No miner must be allowed to proceed into the mine without his check.

Ques.—What method of ventilation lessens the danger of an explosion and, at the same time, reduces friction in a mine?

Ans.—Splitting the air current one or more times so as to ventilate each section of the mine with a separate air split reduces the danger of an explosion occurring in the workings, by conducting the gases generated in each section directly into the main return airway.

This system will make it possible to divide the air between the different sections of a mine according to the need and each section is supplied with a fresh current of pure air traveling at a normal velocity. The frictional resistance of the mine is much reduced and a larger quantity of air is circulated with less power than where a mine is ventilated by a single air current. Also, should gas or dust be ignited in one section, there is less danger of the explosion being propagated throughout the mine.

Ques.—Accidents from blasts and explosions of powder are on the increase. What should be done to reduce them? Answer fully.

Ans.—Where miners are permitted to do their own blasting, strict rules should be made and enforced in regard to the amount of powder permitted to be taken into the mine each day by each man, which amount should be determined by the number of shots the man is to fire that day. This would regulate the charge of powder that is safe to be used. No miner should be permitted to fire a shot or to charge a hole, until the same has been examined by a competent person and found to be safe. Every shot must be fully tamped to the mouth of the hole, with clay and dust taken from the road, or with other incombustible material. No coal slack must be used in tamping a hole. If the mine generates gas no shot must be fired until the place has been examined for gas by the fireboss and pronounced safe for work to proceed.

The safest method to adopt in regard to blasting is to employ competent shotfirers whose duty it is to examine, charge and fire all holes drilled by the miners. The work should be done after the men have left the mine, and plenty of time should be given for its proper performance. No shotfirer should be given charge of a section so large that he is obliged to hurry the work in order to complete his task in the specified time. The work of firing shots must be started on the last of the air and proceed in regular order against the air current. Suitable penalties should be enforced for any violation of the rules and regulations regarding blasting in mines.

Ques.—If the ventilation of a mine is insufficient how may it be increased without increasing the power?

Ans.—In order to increase the circulation in a mine or airway without increasing the power on the air, it is necessary to clean up the airway and remove all obstructions to the passage of the air current. All breakthroughs in rooms and entries must be enlarged to the full section of the airway and kept free of any obstructions, such as the presence of tool boxes, which are too often set in a crosscut to be out of the way of moving cars and where they will not be hit by flying coal or injured by falling roof.

Wherever possible, the distance that the air must travel must be shortened. Where the air can be split without reducing the velocity below what is required to properly ventilate the working places, this should be done to reduce the resistance and provide better ventilation with the same power.

Ques.—How many cubic feet of air will pass per minute along an airway 6 ft. high and 10 ft. wide, the velocity being 450 ft. per min.?

Ans.—The sectional area of this airway is $6 \times 10 = 60$ sq.ft.; and, assuming the average velocity of the air current as 450 ft. per min., the quantity of air passing is $450 \times 60 = 27{,}000$ cu.ft. per min.

FOREIGN MARKETS AND EXPORT NEWS

The Coal Situation in France

The whole of the French industrial situation hinges on the question of coal. For four years it constituted one of the most vital issues of the war, and now, in the face of an important era of reconstruction, it is destined to play a dominant part in the changing economy of the nation.

The position of France as regards the extent of coal deposits is shown in the following estimates of the International Geological Congress held at Toronto in 1913:

	Tons
United States	3,800,000,000,000
Germany	423,000,000,000
England (including 13,000,000,000 tons of lignite)	190,000,000,000
France	18,000,000,000
Belgium	11,000,000,000

In 1913 the production of coal of the leading countries was as follows:

	Tons
United States	562,595,000
England	292,202,000
Germany	278,627,000
Austria	43,800,000
France	40,844,000
Belgium	22,858,000

Although France ranks high among the great nations in the abundance of its deposits and in the quantity of coal produced per annum, its position is far less favorable when the proportional extent of domestic needs is considered. For instance, in order for the annual production to bear the same relation to the population as that which exists in Belgium, France would have to increase its annual output from 40,000,000 tons to about 200,000,000 tons.

The exploitable coal resources of France contained in deposits lying at a depth of not more than 1200 meters (3937 ft.) are estimated as follows:

	Tons
North (Pas-de-Calais)	9,500,000,000
St. Etienne	685,000,000
Alais	958,000,000
Fuveau (lignites)	1,300,000,000
Center	700,000,000
Total	13,143,000,000

By going to a depth of 1800 meters (5905 ft.) this total may be increased to 71,600,000,000 tons. As the aspiration of France is apparently to increase its production to 100,000,000 tons per annum, it will be seen that the above resources would at that rate be totally exhausted in about 150 years.

The situation in 1913, the last complete calendar year before the war, was as follows:

The French exports in 1913 were: Coal, 1,114,000 tons; coke, 205,000 tons; and briquets, 124,000 tons; making a total of 1,443,000 tons. Calculating the value of coke and briquets in terms of coal, the total exports for 1913 reached a figure of 1,500,482 tons, which may be generally accounted for by local reasons.

The imports of coal, coke, and briquets in 1913 and the amounts from each country were:

From	Coal, Tons	Coke, Tons	Briquets, Tons
England	11,257,000	10,000	175,000
Germany	3,491,000	2,393,000	188,000
Belgium	3,670,000	547,000	642,000
Other countries	293,000	120,000	81,000
Total	18,711,000	3,070,000	1,086,000

The consumption in 1913 according to industries was as follows:

	Tons
Metallurgical industries	12,545,000
Domestic heating	11,979,000
Railways	9,069,000
Mining	5,054,000
Gas factories	4,656,000
Merchant marine	1,720,000
Various industries	19,811,000
Total	64,834,000

It will thus be seen that the annual deficit was so considerable as to make the country dependent upon foreign markets for 37 per cent. of its supply. According to customs statistics the cost of these imports amounted to $111,168,000.

But the mere fact of being compelled to import in such large quantities is not of itself the most serious element involved. Such imports are attracted by a scale of prices which places France at a considerable disadvantage compared with the other competing countries of western Europe.

The average value per ton of French coal at the mouth of the mine for the three years preceding the war was as follows: 1911, $2.94; 1912, $2.99; 1913, $3.20.

As compared with the values current in the neighboring countries for 1912, the following differences are noted: England, $2.17; Germany, $2.54; France, $2.99; Belgium, $3.19.

Assuming that this relative proportion governs and is maintained in the selling price, it may be observed that the industries of France purchased their coal at the mine at prices 38 per cent. higher than those in England and 18 per cent. higher than those in Germany.

From the foregoing figures it might appear that France is more advantageously situated than Belgium as regards the price of coal, owing to certain difficulties of extraction in the latter country. This, however, is not the case, for whereas the foregoing values, except for a slight discrepancy, represent the average prices at which industries in England, Germany and Belgium actually purchased the coal which they consumed, the price in France is governed by the scale of its extensive imports and not by the relative value of domestic coal at the mine.

There is an import duty of $0.23 per ton on foreign coal. In 1912 the average price of foreign coal at the port of arrival after the payment of customs duty was $4.97. As this price applied to approximately one-third of the total amount of coal consumed, the average price of the aggregate was thereby raised to $3.67, which is in reality the figure to be employed in the foregoing comparisons.

Calculated on this basis it will therefore be seen that in 1912 the average price of coal as compared with the price in other countries was in reality much higher than it might appear to be.

Effect of the War on Production

Such, in brief, was the coal situation in France before the war. The German invasion in 1914 immediately cut off 24 per cent. of the mines of France by placing the rich regions of the Nord and of the Pas-de-Calais either in the occupied territory or in the army zone reserved for military operations. This deprived France of more than 50 per cent. of its coal production, the annual output of the invaded Departments of Nord and Pas-de-Calais amounting to 27,389,307 tons according to the statistics for 1913.

In addition to this, France suddenly found itself cut off from two of its principal outside sources of fuel supply (Belgium, 5,000,000 tons, and Germany, 7,000,000 tons), and rendered almost wholly dependent upon the aid of England for the fuel essential to the continuance of its industrial activities. The mines remaining in French possession had a productive capacity in normal times of some 19,000,000 tons, or about 1,600,000 tons per month. The possible length of the war being discounted and the tremendous extent to which its demand would tax the industrial resources not being realized, miners were mobilized with the army. The result was general disorganization and a decrease in production of the few remaining French mines of 60 per cent.

No sooner was this error recognized than steps were taken to withdraw the miners from the front. Refugee miners from the invaded regions were enrolled, and by March, 1915, the normal production of all mines remaining in French possession was virtually restored. The labor necessary to accomplish the effort made by France in the pressing matter of coal production during the war was secured through the demobilization of 50,000 French miners and the utilization of 14,000 enemy prisoners of war. The following scale of production shows the practical results obtained from this effort: January, 1915, 1,532,000 tons; January, 1916, 1,676,000 tons; December, 1916, 1,861,000 tons; October, 1917, 2,783,000 tons.

Comparative Output for 1913-1918

A more elaborate comparison gives a much clearer conception of these results, so gratifying and so promising to the French people, and affords a better understanding of the deplorable situation during the first six months of the war:

Mines	1913 Tons	1914 First Six Months Tons	1914 Second Six Months Tons	1915 Tons	1916 Tons	1917 Tons	First Ten Months of 1918 Tons
Mines of Nord and Pas-de-Calais (invaded)	27,389,307	9,226,227	.....	.....	.....	.....	.....
Mines of Nord and Pas-de-Calais (not invaded)		1,331,241	1,981,399	7,382,292	8,195,025	11,450,463	6,587,250
Other mines	13,454,911	5,567,646	5,461,745	12,150,571	13,115,040	17,441,240	15,730,570
Total production	40,844,218	19,125,114	7,443,144	19,532,863	21,310,065	28,891,703	22,317,820

Coal Shortage Relieved by Imports

Imports on which the nation so widely depended were pushed with equal vigor, Belgium and Germany having been lost as sources of supply. The following table illustrates the manner in which the problem of the importation was met:

Year	From England Tons	From Belgium Tons	From Germany Tons	From United States Tons	From Other Countries Tons	Total Tons
1913	11,257,431	3,659,669	3,482,287	.....	293,736	18,693,123
1914	10,759,058	2,032,099	2,477,735	.....	161,366	15,430,258
1915	18,918,203	45	737	145,398	3,355	19,067,738
1916	18,711,125	14	.....	53,883	9,701	18,774,723
1917	15,848,734	16	247	57,136	2,135	15,908,268

For some time Parliament has been reluctant about granting new coal-mining concessions, and for the past 10 years has granted none at all. This has discouraged coal prospecting and prevented the possible opening up of new mines in regions where workable deposits had been found to exist. The attitude of Parliament is inspired by objections to the mining law of 1810 which provides for the granting of concessions in perpetuity without any participation on the part of the government in the profits of the mines. A bill is now being debated which purports to amend these features of the statute by limiting concessions to 99 years and by providing for government participation in the profits.

According to the gist of the debates it is believed that such a bill would greatly encourage mine development and would afford an effective means of encouraging artificially the working of small mines as well as of those where extraction is difficult.

In addition to the above measures the utilization of inferior, or secondary, fuels is being strongly urged. France is rich in peat, and lignite exists in appreciable quantities. It is estimated that with proper encouragement these resources could be made to contribute largely to the saving of coal.

Netherlands Short of Coal

The nonarrival of British and German coal during the month of December, 1918, writes Commercial Attaché Paul L. Edwards, The Hague, under date of Jan. 5, 1919, has reduced the stock of coal in the Netherlands to such a low point that drastic measures are to be instituted to reduce the consumption of coal during the month of January, 1919. It is hoped that before February coal will arrive from the United States and from England, says Mr. Edwards, and that permanent arrangements will be made for Belgian or German coal. If not, the train service will be considerably reduced on Feb. 1.

The city of Amsterdam put into force on Jan. 6 the following regulations, with a view to saving electricity: Cafés, restaurants, shops and stores were to use only half as much electricity as they had been allowed since Oct. 30 last. Private residences were to reduce the use of electricity to 65 per cent of the amount used in November, 1918. All factories, etc., were to reduce their consumption of electricity to 65 per cent.; furthermore, they were not to use any electrity whatever for industrial purposes between 4 p.m. and 10 p.m. This restriction in hours did not apply to factories engaged in the preparation or manufacture of foodstuffs; such factories could recommence the use of electricity at 6 p.m., and the amount of electricity which they could use would be determined by the State Coal Bureau.

The "Maasbode" of Jan. 4 stated that the Netherlands Minister of Foreign Affairs was to send a representative to Brussels on Jan. 6 to endeavor to conclude the arrangement for the exchange of Belgian coal for Dutch milch cows. It is understood that Holland is also to offer about 10,000 work and army horses for an additional amount of coal.

During the week ending Jan. 5, 1919, 7000 tons of coal arrived from Germany, but this was to be used expressly to replace a similar amount of coal that was borrowed for the purpose of bunkering vessels that are taking Russian prisoners to Danzig. It is understood, however, that negotiations are being carried on with the Germans to secure the monthly import of 40,000 tons from the Ruhr district. The Algemeen "Handelsblad" of Jan. 4 stated that the first train to bring coal under this proposed arrangement would arrive on Jan. 7, and that thereafter there would be two coal trains regularly each day, providing unexpected transportation difficulties did not interfere.

Sweden offers American exporters of coal a market for steam coal. Those interested should communicate with Consul Wallace J. Young, Goteborg, Sweden.

Foreign Freight Rates

W. W. Battie & Co.'s coal trade freight report for Feb. 24 states that the demand for steamers to carry coal to South American ports is still very urgent, and there are few free boats available. South American shippers will now also entertain sailing vessels at the Chartering Committee's maximum rates, if tonnage is not too far distant. West Indian coal freights are also showing renewed activity after a long period of dullness. All recent fixtures have been at the Chartering Committee's maximum rates, which are as follows:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge.

Sail (maximum)—Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net; Santos, $19.50 net, Buenos Aires, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. (Gross rates $1.50 per ton in excess of net rates). On all the foregoing rates, charterers pay vessel's towage to coal port. To Nitrate Range, $16.50 gross prepaid. (Same rate steam.)

The Chartering Committee's rate by steam is $19.50 net; with 1000 tons dis. to Rio, $19.50 net, 1000 tons dis., or $21,600 tons dis. to Santos, $18.50 net, 1000 tons dis. to Buenos Aires, and $19.50 net, with 750 tons dis. to Montevideo.

Swedish Concern Wants Coal from America

It is reported by an American consular officer that a company in Sweden is desirous of purchasing American coal and coke. Correspondence with the Swedish firm may be in English. Reference. The address may be obtained by writing to the Bureau of Foreign and Domestic Commerce, Washington, D. C., or any of its district offices, and asking for information on Opportunity No. 28,525.

United States Supplies Bulk of Brazilian Coal

The war has changed Brazil's import trade in coal, which was formerly entirely in the hands of Great Britain, to the United States. Of total imports valued at $23,343,069 in 1917, the United States supplied $19,087,107 worth. Although the c. i. f. value of the coal imported increased from $18,651,927 in 1916, the tonnage decreased from 1,024,487 tons in 1916 to 818,327 tons in 1917, the average price having risen from 75 to 114 milreis ($18.75 to $28.50) per ton. While the United States at present controls the coal trade, under the present selling methods it seems improbable that this trade will be retained. Although they have had four years of opportunity, not one of the important coal companies of the United States has found it expedient to establish a permanent coal depository, which is largely the secret of British success in this market in the past. The imports of coal briquets declined to an insignificant value of $137,046.

Exports of Anthracite and Bituminous Coal and Coke, by Customs Districts and Countries—December, 1918

COAL AND COKE NEWS

What Happened in January

[The bracketed figures in the text refer to pages in the present volume and should the reader desire further information he can obtain it by reference to the pages indicated.]

Jan. 1—The United States Fuel Administration removes all limitations on the duration of contracts for coal and coke made under order of Dec. 25, 1917, with amendment of July 26, 1918—United States War Department commences to handle its own coal requirements without reference to Fuel Administration—Men of Marvine colliery, of Hudson Coal Co., return to work [XV, 152].

Jan. 2—The United States Fuel Administration announces that it has induced the carbon-black manufacturers of Grantsville, W. Va., to cease using the natural gas of West Virginia for that purpose but to operate in Wyoming and Louisiana where gas cannot be otherwise utilized. This will save 15,000,000 cu.ft. of gas and 5000 gal. of gasoline per day—John E. Williams, Federal fuel administrator for the State of Illinois, dies at his home in Streator, Ill.

Jan. 3—Fire at the plant of the Steele Coal Co., Mossy Bottom, near Williamson, W. Va., destroys store and office buildings and causes a loss of $20,000.

Jan. 4—General March states that 6000 anthracite coal miners have been ordered released by the army [XV, 151]—Frank E. Harkness made Solicitor of United States Fuel Administration.

Jan. 5—George H. Cushing, since 1907 editor of the "Black Diamond," becomes managing director of the American Wholesale Coal Association—Practically all restrictions upon the sale and shipment of bituminous coal for bunkering purposes at points north of Cape Hatteras removed by order of United States Fuel Administration.

Jan. 7—Director of Railroads makes report to President in which he declares that the zoning law greatly helped the railroads in meeting the demands of the nation for transportation [XV, 150]—House of Representatives passes lignite bill, providing funds to determine the commercial practicability of using lignite in producing fuel oil, gasoline substitutes, ammonia, tar, solid fuels and gas for power and other purposes [XV, 191].

Jan. 8—George R. Sheldon, treasurer, Republican National Committee and director of the Union Colliery Co., is seriously injured at Dowell, Ill., by being crushed between a trip and the coal rib. Dies Jan. 14.

Jan. 9—Strike of 16,000 marine workers ties up more than 1000 boats in New York Harbor, causing railroad embargo —Burning natural gas in flambeaux, for outside light in daylight hours in inefficient apparatus, in larger quantity than needed, or in any manner not making efficient use of fuel, is forbidden.

Jan. 10—All fuel conservation provisions of Fuel Administration withdrawn, except those relating to waste of natural gas by free consumers or by inefficient appliances or through carelessness [XV, 165]—Restrictions on domestic and foreign shipments of egg and pea size of anthracite removed, though chestnut and stove continue to be restricted [XV, 165].

Jan. 14—The Cleveland & Western Coal Co. is fined $1000, to be paid to the Red Cross, for disposing of coal shipped to the McKinney Steel Co. for byproduct coke oven use. When the steel company said it had no need for the coal the coal company sold it to local consumers in violation of the zoning order—Explosion of gas at No. 9 mine of Pennsylvania Coal Co. seriously burned three men [XV, 209].

Jan. 15—Southport Miners' Federation demand that British Government demobilize all miners in army and require that corporations give them an increase in wage of 30 per cent. [XV, 210].

Jan. 16—Strike at Oneida colliery of the Lehigh Valley Coal Co., near Freeland, Penn., about the discharge of a careless man [XV, 193]—Store building and several dwellings of Standard Island Creek Coal Co., at Taplin, W. Va., are destroyed by fire [XV, 252].

Jan. 17—Fuel Administration announces that on Feb. 1 all district representatives would cease to function except for the purpose of preparing records of the work done to Jan. 31 [XV, 191]—Lawrence Mitchell, assistant business manager, is made property custodian of the Fuel Administration—Orders of May 16 and July 16, 1918, are suspended by Fuel Administration. These orders prohibited selling, shipping, delivering or distributing smokeless coal received at Lake Michigan or Lake Superior docks except for making illuminating gas, byproduct coke or coal briquets or other purposes designated by Fuel Administration—Coke and all coal, except Pennsylvania anthracite, is relieved of price restrictions and zoning rules. Filing of contracts with Fuel Administration is no longer required [XV, 191]—Director General of Railroads declares that Railroad Administration is not trying to force down coal prices [XV, 191]—Norfolk and Angle Tipple of Pocahontas Fuel Co. destroyed by fire [XV, 252].

Jan. 18—Strike for minimum wage at Heidelberg collieries, Nos. 1 and 2 ends Jan. 27 [XV, 238, 284]—Two men fatally burned in an explosion of gas at No. 2 shaft, Alden Coal Co. [XV, 252].

Jan. 20—Mine fire prevents six men from escaping from Mt. Braddock mine of the W. J. Rainey Co., Mt. Braddock, Fayette County, Pennsylvania. Two men lose lives in rescue work. The six men are ultimately rescued on Jan. 24 [XV, 252, 272].

Jan. 21—Harold B. Harris appointed Custodian of Records, Fuel Administration [XV, 237]—Cage in Hammond colliery shaft near Shenandoah frees itself of the guides and tears timbers loose so that they fall to the shaft bottom [XV, 252] —No. 5 breaker, of Hudson Coal Co., destroyed by fire [XV, 252].

Jan. 22—Fuel Administration decrees that all orders for the requisition of coal and coke are cancelled and annulled from Jan. 31 onward [XV, 236]—Fuel Administration announces that the Bureau of Labor, which works under the Fuel Administration, will continue its existence till the close of the war [XV, 238]—Employees of Yorkshire, England, mines, numbering some 150,000 men, go on strike for an extra 20-min. lunch time [XV, 239].

Jan. 23—Convention of miners in Winding Gulf field meets at Beckley, W. Va., to discuss a new wage scale which, as decided on by the convention shall give 12c. per ton more to miners and $1.50 to $1.75 per day to day workers [XV, 239].

Jan. 24.—George E. Howes is appointed historian of Fuel Administration.

Jan. 28—Shipping rates from the United States to the United Kingdom, Havre, Bordeaux, Antwerp, Rotterdam, Marseille, Cette, Genoa, Naples, Colombo, Calcutta, Rangoon and Madras reduced by British Ministry of Shipping roughly two-thirds—The ratification of the Prohibition Amendment to the United States Constitution is officially announced by the Secretary of State.

Jan. 29—War Trade Board announces that the government of Great Britain will on Mar. 1 prohibit the importation of specified classes of manufactured goods from the United States—Mine workers open coöperative store in Shenandoah [XV, 284]—Three miners are killed by the explosion of a pocket of gas at Goodyear Mine, Smoky Run, in Clearfield County, Pennsylvania [XV, 295].

Jan. 31—Treasury Department and Department of Interior reassume control of the supply of their coal requirements without reference to Fuel Administration—Order of requisition for coal and coke are annulled—Maximum prices for anthracite suspended, also all other coal and coke regulations but three [XV, 282].

Harrisburg, Penn.

Senator Albert Davis of Lackawanna has introduced in the Senate a bill aimed at remedying the mine cave conditions as they exist in Scranton and the immediate locality. The bill was drafted by Draper Lewis, former dean of the school of law, University of Pennsylvania.

The bill makes it unlawful to mine or remove coal as to cause the collapse of any public building or structure used as a place of resort, assemblage or amusement, including churches, schools, hospitals, theaters, hotels and railroad stations, also streets, highway roads, bridges or other public passageways, any tracks, roads, pipe lines, wires or other facilities used in the service of the public by any municipal corporation or public service company as defined by the public service company law.

Persons upon conviction of violation of the first provisions will be subject to fine not exceeding $5000, one year's imprisonment, or both, at the discretion of the court. Every president, director, general manager, superintendent or other person having supervision over any mine or mining operations, who wilfully participates in or connives at any violation of any of the provisions will be liable to the penalties.

A subsidence of the surface will constitute prima facie evidence and prosecution for violation of the act may commence at any time within two years from the time the subsidence appears on the surface. A threatened violation of the provisions may be restrained by an injunction. If one section of the Lewis act is declared unconstitutional it will not affect the other provisions of the measure.

The bill drawn up by Dr. Lewis differs greatly from the bill which Senator Davis intended introducing, which was the one got up by the Scranton Surface Protective Association. Probably the most radical difference is that the measure takes in all coal operations, whether it be anthracite or bituminous. The Surface Association bill specified anthracite operations alone.

As the bill includes all coal-mining sections in its provisions, there will be a greater number of representatives and senators interested in it during its course through legislative channels. It is understood that arrangements are already being made for a public hearing on the bill. This will in all likelihood be held within a month.

Senator Crow has introduced a bill which provides that the Secretary of Internal Affairs be made the custodian of all deeds, contracts, maps, surveys and other documents or instruments relating to the titles of real estate owned or hereafter to be acquired by the Commonwealth.

Charleston, W. Va.

Coal production has grown less and less in West Virginia, making it certain that February would prove to be one of the poorest months in recent years in point of production. From the first of February, when so many companies shut down their mines, until the latter part of that month many mines in addition were closed down because of lack of orders. Inasmuch as most of the mines of the state are not operating on more than a 25 per cent. basis, that means of course that they are being operated on an average of only one or two days a week. Idleness so prevalent throughout the coal fields of West Virginia has been relieved here and there by orders, but a resumption in such instances has been more than met by a suspension of operations at the plant of other companies.

Throughout all the depression so much in evidence in recent months producers of coal in West Virginia have not yielded in price, and during the week ending Feb. 22 except in rare instances coal prices were being maintained. Coal men know that in the course of the next 30 or 60 days business will pick up, because at this moment

coal is being used faster than it is being mined. For that reason it is freely predicted that there will be a slight improvement in the demand by Apr. 1 and that by July 1 there will be a general resumption of trade.

In West Virginia just at this time demurrage costs are cutting a considerable figure, not only because of the high demurrage rates, but because of the gamble indulged in by many operators in loading empties at their disposal and trusting to the receipt of orders sufficient to utilize the cars loaded. There have been brought to light several instances recently where small operators have had stiff demurrage bills to meet because of the producer taking a chance on getting orders.

One Virginian field operator finds high ocean rates and excessive demurrage rates operating to clog the wheels of the mining industry. He happened to have a personal interest in a recent demurrage case where one car in excess of the number ordered was shipped to the South and refused by the consignee. The car being on a branch line, it was found difficult and even impossible to get rid of it. After the consignor had been attempting for some time to dispose of the extra car of coal, he was notified by a railroad company of the high rate of demurrage running against the unloaded car. The only way the consignor was finally able to get rid of the car was by giving it away and by paying the donee $60 for unloading it in addition to demurrage charges of $123.80 and the expense of the trip. With ocean rates high and with strikes in swing in so many South American points, the Virginian field operator pointed out the futility of trying to market coal in South America at the present time.

New York, N. Y.

Samuel B. Crowell, who was the retail coal-dealer advisor on the staff of Federal Fuel Administrator Garfield, at the meeting of the New York State Coal Merchants' Association at the Hotel Pennsylvania, New York City, on Feb. 27, said that cooperation of the three branches of the coal trade is most essential; that is to say, between the operator, the jobber and the retail distributor.

The association adopted resolutions protesting against amendments now pending in the State Legislature to the workmen's compensation law, and to the bill to establish a system of compulsory health insurance for the benefit of the employees and their dependent families, which requires the employer to contribute in all cases not less then 50 per cent. of the cost of the insurance, and in some cases three-quarters or the whole of it.

Arthur F. Rice, Commissioner of the Coal Merchants' Association of New York, predicted that coal prices will come down, but that the most optimistic man cannot expect to see this done at once. There must be a rather gradual reduction in the cost of labor and materials first. That the readjustment will and must come is certain; and the indications are that it is not far off.

Other speakers included Harry T. Peters, of Williams & Peters, and S. Brinckerhoff Thorne, of Thorne, Neale & Co., who was a member of the Fuel Commission sent to Europe by the U. S. Fuel Administration last October.

Failure of the marine workers and boat owners to come to an agreement resulted in a strike order being issued by the workers late on Monday of this week, involving about 16,000 men. If effective it would result in a complete tying up of the tugs and barges in the New York harbor. At the time the order was issued it was said that the only exemptions would be army transports and hospital ships returning from France with soldiers. The strike order became effective at six o'clock Tuesday morning.

The men stopped work several weeks ago when their demands for an eight-hour day and wage increases were refused by their employers. At that time President Wilson instructed the War Labor Board to take hold of the situation and the men returned to work pending a hearing conducted by the Government. Subsequently the entire matter was referred to V. Everit Macy as umpire, and last week he handed down his decision granting the workers an eight-hour day, but without increased pay.

The men did not take kindly to the award and resumed their strike talk with the result that after several conferences the private boat owners organization on Monday of this week made three concrete propositions as follows: That the workers accept the Macy award; That the workers accept a wage increase (amount not stated) and working conditions remain as they now are; that the workers deal with the private boat owners and create a joint board to adjust their differences.

PENNSYLVANIA

Anthracite

South Scranton—Coal underlying the Daniel Webster and Wendell Phillips school buildings has been purchased by the school board at a cost of approximately $1000, according to deeds recorded. The coal in place was purchased for 35c. a ton. In selling the coal, the company stipulates several reservations, among them being that the Delaware, Lackawanna & Western, Coal Department, has no right to remove the coal, but that the company is allowed to make tunnels and passages and that they they shall incur no liability whatever from damages which may occur from caves or any other cause.

Minersville—The Oak Hill colliery, which has been idle for three weeks because of the dullness in the anthracite business, resumed operations on Feb. 26, giving employment to 800 men and boys. Another indication of revival in the anthracite business is the development of a big tract of coal land at Port Carbon, begun on Feb. 25. There are millions of tons of coal in this tract. The big Westwoods culm banks, owned by the Philadelphia & Reading Coal and Iron Co., have been leased to George Keiser, a well-known independent operator, and preparations have begun for the immediate marketing of the half million tons of coal there. These banks were deposited in 1860 and are rich in pea coal and nut coal, while the river nearby makes the work of washing easy.

Hazleton—M. S. Kemmerer & Co., operators of Sandy Run Colliery, have suspended operations and are taking out their pumps and mining equipment. The store has been closed and all work stopped. The mining conditions at this colliery have been unfavorable for some time, a squeeze having made coal recovery very expensive. Many of the suspended miners have found work with the G. B. Markle Co. and are removing their families to Freeland. Stripping contractors look forward to a prosperous summer season, although at present, their equipment is idle. The Lehigh Valley Coal Co. will strip the basin, between its Spring Brook and Spring Mountain collieries. The newly organized Raven Run Coal Co. is reported to have a stripping proposition under consideration at Raven Run.

Jeddo—The Mexicans employed by the G. B. Markle Co. at this place have nearly all left. The management announces that no more will be employed.

Scranton—The Lackawanna Coal Co. closed two of its collieries at this city and will prepare the coal at other breakers due to the cheaper underground haulage cost.

St. Clair—The Buck Run Coal Co. (Neale & Thorne) has taken over the Ellsworth colliery of G. M. Keiser, located near this place. The colliery is on a Philadelphia & Reading Coal and Iron Co. tract, and consists of a small breaker and washery, with a capacity of 300 tons per day.

Scranton—In the producing of 10,027,901 tons of coal in the fifth, sixth and seventh inspection districts of Lackawanna County during 1918, 60 men lost their lives, 133 were injured, 55 wives were widowed and 146 children orphaned. The number of tons produced per fatal accident, inside and outside, was 460,212, and the number of persons employed per fatal accident was 827. Reports from the remaining four districts have not been compiled.

Taylor—Satisfied that the company was negligent in not providing a safety block at the head of the shaft, a coroner's jury, sitting at an inquest into the death of the two men killed in an accident at the Greenwood shaft of the Hudson Coal Co., place responsibility for the accident upon the coal company. Witnesses testifying at the inquest stated that a headblock at the head of the shaft had been removed two months ago, and had not been replaced. Two men were killed and two others seriously injured when two runaway mine cars crashed into the mouth of the shaft, falling down upon the cage on which the men were riding.

Wilkes-Barre—A mine fire on No. 13 plane, Baltimore vein, that had gained considerable headway in the South Wilkes-Barre No. 5 colliery of the Lehigh and Wilkes-Barre Coal Co., was discovered on Feb. 21, and after attempts to put the fire out by means of water and other materials had failed to check it, that portion of the mine where the fire is raging was sealed up on Feb. 23. A concrete wall has been placed at all openings leading to the fire. This wall will have to remain for an indefinite period before it can accomplish its purpose. The fire will in no way interfere with the output of the colliery.

Freeland—The East Point Coal Co., operator of the Pond Creek colliery near Freeland, Penn., has closed its mine for an indefinite period. Three hundred men are made idle by the suspension. The Spring Brook and Spring Mountain operations of the Lehigh Valley Coal Co. have been completely shutdown. The mules have been hoisted and their shoes taken off; foremen are manning the pumps. Lumber is on hand to repair the Spring Mountain breaker. The union officials are much concerned over the idle mine workers, and consulted with General Manager Thomas, who promised them early action.

Bituminous

Vintondale—Etta Gibson and others have sold the coal underlaying a tract of 112 acres in Buffington township, Indiana County, to the Vinton Land Company, a subsidiary of the Vinton Colliery Co. The consideration was $10,722.65.

Savan—The Dor-Mar Coal Co. put its new plane and tipple into commission last week and is now loading coal from one of its mines on the John Hamilton farm. Work has also been started on a new opening in the Upper Freeport vein and the first timbers were put into place the same day the new tipple was put into commission. Both mines will load over the same tipple. Shipments are made over the Buffalo, Rochester & Pittsburgh Railroad.

Hollidaysburg—For several months the Allegheny Water Co. has had an injunction against the Russell Coal Co., of Altoona, to prevent the latter from constructing a tram road and tipple on a portion of the watershed which supplies the City of Altoona with water. The building of the tram, which would be about 3000 ft. in length, would shorten the coal haul to Altoona by about six miles and put the coal on the Buckhorn Pike only three miles from the city. The court succeeded in bringing the two companies to an agreement by changing the proposed tram road to another point. This was agreed to by both companies and will operate to better advantage for both parties. The tram will be constructed immediately and will relieve Altoona of any future coal shortages. Electric locomotives will be installed in the mine and on the outside tramroad.

Indiana—According to the annual report of Mine Inspector Thomas S. Lowther, of the 25th district, for the year 1918 there were 6,191,735 net tons produced, of which 6,082,332 were shipped to market. There are 65 mines in operation employing 5758 men; six of these mines are new operations opened during the year. There were 16 fatal accidents, 14 being inside the mines and two outside. There were 386,983 tons of coal produced and 360 men employed per fatal accident. There were 89 non-fatal accidents, 79 of which were inside the mines. There were 65 persons employed per non-fatal accident. All the mines of the district are in Indiana County. The largest producer was the Jefferson and Clearfield Coal and Iron Company with a production of 1,894,776 tons and the Pittsburgh Gas Coal Co., second, with 1,188,460 tons.

Irwin—The production of coal of the bituminous mines in the Nineteenth District in the year 1918 was among the respective companies as follows: Westmoreland Coal Co., 2,310,440; Ocean Coal Co., 827,078; New York and Cleveland Gas Coal Co., 590,897; United Coal Corporation, 465,443; Keystone Coal and Coke Co., 428,210; Irwin Gas Coal Co., 229,240; Delmont Gas Coal Co., 218,819; Union Coal and Coke Co., 157,773; Irwin Valley Gas Coal Co., 80,698; W. B. Skelly Coal Co., 78,232; Eiseman Coal Co., 64,362; Export Mining Co., 44,600; McAllister & Gray Coal Co., 41,657; Salem Gas Coal Co., 40,344; Westmoreland Gas Coal Co., 39,138; A. H. Pollins, 37,704; Cambria Steel Co., 36,650; Byerly Gas Coal Co., 35,421; Edwards Coal Co., 29,290; Larimer Gas Coal Co., 27,825; miscellaneous companies, 90,861; total, 5,874,682 net tons. All the mines are in Westmoreland County.

Greensburg—Inspector J. J. McDonald of the Eleventh bituminous district, which includes the region surrounding Greensburg, in his report for 1918 shows that the total production of coal in his district was 6,889,298 tons, of which Westmoreland county contributed 6,631,534, and Fayette county 257,764 tons. Of the companies the heaviest producers were the H. C. Frick Company, with 3,315,772 tons; the Keystone Coal and Coke Company, 1,227,184 tons; the Jamison Coal and Coke Company, 739,150 tons; Greensburg Coal Company, 450,769 tons; and the Mount Pleasant-Connellsville Coke Company, 328,528 tons.

Brownsville—The controversy between J. Harte Hillman, Jr., of Pittsburgh, Penn.,

President of the Hecla Coal and Coke Co., and T. J. Brennan, of Uniontown, Penn., president of the Thompson-Connellsville Coal and Coke Co., over the control of the latter company, which it was announced last week had been settled out of court, has been settled by agreement that no special meeting of the stockholders would be held at this time to elect new officers, but that Mr. Brennan would retain the presidency till the next regular meeting of the directors next July.

WEST VIRGINIA

Glen White—Some changes are to be made in the plans of the E. E. White Coal Co. in connection with the construction of a steel tipple at this place. The company had a complete survey made by a New York firm of engineers and upon consideration of a report made by the engineers will broaden its plans somewhat with a view to securing the greatest results in mining and loading coal from the various seams under development.

Fayetteville—Additional and unlooked-for orders have enabled the New River & Pocahontas Consolidated Coal and Coke Co. to start its mines at Minden going again, the plants having been closed down for two or three weeks because of insufficient orders. When operations were suspended at the Minden mines it was feared that it would be for an indefinite period, but unexpected orders caused a resumption of operations.

Philippi — Coal companies and coal properties located in various parts of the state which have been under the control and management of William Taylor George, of Philippi; A. A. Lilly, of Charleston; Samuel Morans, of Youngstown, and others, have been acquired by the Beacon Coal and Land Co. Among such properties are the Randolph Smokeless Coal Co. and the Hartlands, Rich Mountain, W. Va., said to be worth $225,000; Clay County Fuel Co., located near Hartland, $65,000; Morans Coal Co., Middle Creek, Clay County, $60,000; and 85 acres in the Jones tract at Wilmoth.

Rosebud—G. M. Shoemaker & Co., whose offices are at Clarksburg, W. Va., have taken over the property of the J. M. Macdonald Coal Mining Co., of this place, consisting of the Rosebud Nos. 1 and 2 mines, the Gilbert, on the Baltimore & Ohio Short Line, and the Hornor mine, at Hornor, W. Va., on the Weston & Pickands division of the Baltimore & Ohio. The combined capacity of the four mines is about 20,000 tons per month at present, but the new owners expect to increase this materially within a short time. The Matthew Addy Co. is to act as the sales agent for all operations.

Clute—Officers have been elected and plans perfected by the Belick Knob Coal Co., reference to which was made in *Coal Age* a few weeks ago. The new company will be headed by Thomas M. Davidson, of Huntington, with W. A. Garrett, of Charleston, as secretary and treasurer. Operations will be under the direction of Floyd B. Thompson. The plant of the company, as already indicated, is to be built at Clute, Fayette County, where the company will have its operation. It will require about three months to construct the plant, but at the end of that time the company expects to be able to begin the mining and shipment of coal. While the plant is under way the offices of the company will be located at Clute. New River coal will be produced, the company planning to develop part of a tract of 400 acres of coal secured from the Sewell Valley Coal Co.

OHIO

East Palestine—J. A. Meek, of East Palestine, has purchased the Mollenkopf farm near here and is planning to open a coal mine in No. 6 seam. The vein is 4 1-2 ft. thick.

Wellston—The United Mine Workers recently in session at this place adopted a resolution asking the Railroad Administration to purchase in Ohio coal used on Ohio railroads. It was claimed that some Ohio roads are using West Virginia coal.

INDIANA

Brazil—The Clay Products Co., operating two large plants near here, have leased the Austin Shattuck farm of 300 acres near Hoosierville and will begin at once to remove the coal and clay products underlying the land. By leasing this tract the company will be able to mine its own coa, there being a fair-sized deposit of good grade block underlying the farm.

ILLINOIS

Cuba—Mine No. 1 of the Donk Coal Co. has closed down indefinitely. It employed several hundred men.

Springfield—The state miners' examining board will hold a test in this city Mar. 15. Other dates for examinations are as follows: Mar. 6, Duquoin; Mar. 7, Christopher; Mar. 8, Harrisburg; Mar. 10, West Frankfort; Mar. 11, Herrin; Mar. 13, Belleville; Mar. 14, Staunton; Mar. 17, Danville; Mar. 19, Peoria; Mar. 20, Canton; Mar. 21, Macomb.

Hanna City—Through the efforts of W. E. Kidd, state mine inspector, a permanent organization has been effected of Hanna City miners in first-aid relief work. A class of 52 miners has been under instruction. It is said that the work will be organized in every mine local in Illinois. Alexander Miller, of the United States Bureau of Mines, assisted by Mr. English, of the Illinois State Department of Mines and Mining, were also active in the work.

Du Quoin—Coal mining is practically at a standstill in this section. The 1500 men employed at the respective mines here are putting in only two or three days per week as a result. With the exception of the Kathleen mine, located at Dowell, five miles south of here, the mines have not averaged over three days a week for some two months or more, while without warning, about three weeks ago the Dowell mine joined in with the rest and is now working about half time.

Du Quoin—George W. Leek, financial secretary of the Elkville miners' union, is the author of a resolution, which if adopted by the Illinois miners' organization, will provide a benefit of $2000 for the family of every miner at his death. At this time the family of each miner receives $250 at his death. There are 80,000 union miners in Illinois, and Leek declares his idea will prove to be a practical solution of the problem of supporting the dependents of the members of that organization.

Springfield—Tonnage figures compiled by the Illinois Department of Mines and Miners show the great falling off after the signing of the armistice. In October 8,286,000 tons were hoisted, in November 6,286,000 and in December 6,000,000 tons. For the year ending June 30, 1918, a record of approximately 90,000,000 tons was set; and if the war had continued it was expected that 100,000,000 tons would have been reached for the year ending June 30, 1919. The average normal yearly tonnage is between 50,000,000 and 60,000,000.

Centralia—Because of the congested conditions which have developed between Du Quoin and Centralia in the last year and a half, the Illinois Central Railroad Co. has made extensive improvements in its equipment which will greatly facilitate the handling of coal. A five-stall roundhouse is being erected at the north end of the switch yards at Du Quoin, and this will be completed soon. In addition to this the company has excavated an immense reservoir near the site of its old reservoir at Du Quoin, which is not large enough to supply the demand that will exist as soon as the new roundhouse is in use. The water will be piped underground from the reservoir to tanks near the roundhouse.

KANSAS

Frontenac—The Dittman-Wachter Coal Co. has recently completed a new washhouse at its mines here. The building is modern in every respect and will fill a long felt want.

Foreign News

Minto, N. B.—Nearly all the coal mines in the Grand Lake mining field have been closed because of the unsatisfactory conditions of the coal market. The only mines in operation are those of the Minto Coal Co., which are only kept going because the company has large contracts with the Canadian Pacific Railway Co. The Government has been asked to have the output of other mines used on the Canadian National Railways to make it possible for them to resume operations.

Victoria, B. C.—The total coal production of the coal mines of British Columbia for the month of January, 1919, was 243,516 tons, which represents an increase of 31,509 tons over the production of the month of December, 1918. There was a drop in output tonnage at the Corbin (B. C.) colliery and Princeton (B. C.) collieries, which was due in the former case to weather conditions and in the latter to a fire in the mine. The loss would amount to approximately 3000 tons.

Edmonton, Alta.—The annual report of John T. Stirling, chief inspector of mines for Alberta, shows the production during 1918 of 6,148,620 tons of coal, 100,470 tons of briquets and 32,858 tons of coke. The number of mines in operation during the year was 317, including 70 new mines and nine which had been reopened. The number of mines abandoned was 71. The average number of men employed was 2633 above ground and 6141 below ground. The number of fatal accidents was 21, and there were 16 serious accidents. Of the total amount of coal mined during the year 3,440,154 tons was sold in the province, 101,189 tons in British Columbia, 1,372,439 in Saskatchewan, 511,168 in Manitoba, 629 in Ontario and 133,276 tons in the United States.

Personals

A. A. Straub has been elected vice president and general manager of the Superba Coal and Coke Co., Frick Building, Pittsburgh, Penn., effective Jan. 1, 1919.

William H. Brown, of Gloucester, Ohio, general superintendent of the Ohio Collieries Co., has resigned his position, effective when his successor is appointed.

F. J. Patton, secretary of the Northern West Virginia Coal Operators' Association, Fairmont, Va., has resigned his post in order to devote his entire time to his personal business.

W. T. Miller, formerly of the freight traffic department of the Pittsburgh & Lake Erie R.R., Pittsburgh, Penn., has been appointed traffic manager of the Industrial Coal and Coke Corporation, New York, N. Y.

J. A. Jefferis, of St. Louis, Mo., manager of the Kerens-Donnewald Coal Co., has been appointed fuel agent of the Illinois Traction System, which requires an annual tonnage in excess of 500,000. He will continue to make his headquarters in St. Louis.

W. T. Burgess, superintendent of coal-mining operations of the Bessemer Coal, Iron and Land Co., at Belle Ellen, Ala., has resigned his position to accept one as safety inspector of coal mines for the Republic Iron and Steel Co., effective Feb. 15. Mr. Burgess will have his headquarters at Sayreton, Alabama.

A. B. McLaren, president of the Citizens Trust and Banking Co., Marion, Ill., and manager of the Chicago and Big Muddy Coal Co.'s properties, has accepted the superintendency of the O'Gara properties at Harrisburg, Ill., to succeed **R. M. Medill**. The O'Gara interests have twelve mines in operation in Illinois and Indiana.

George E. Henry, for several years president of the Allegheny Valley Operators' Association, at the annual meeting in Kittanning, Penn., definitely retired and L. B. (Doc.) Lewis, manager of the Acme Coal Co.'s mines at Rimersburg, was elected president in his stead. Mr. Henry stated that he begun business as a miner at $1 a day. He retires with a fortune.

Thomas Houlton, of Gloucester, Ohio, has resigned as electrical and mechanical engineer for the George M. Jones interests, comprising the Ohio Collieries Co. in the Hocking Valley and Cambria Collieries Co. near Bellaire, Ohio, and has opened an office as consulting mechanical and electrical engineer at Johnstown, Penn. Mr. Houlton before going to Ohio about a year ago was for several years master mechanic for the Merchant Coal Co. and the United Coal Co.

Clarence E. Patrick has been appointed district sales manager for Rockford, Ill., for W. P. Rend & Co., who have mines in the Hocking field of Ohio, as well as in the Franklin County district of Illinois. Until recently Mr. Patrick was vice president of the Calloway Fuel Co., of Milwaukee, but resigned, and made a connection with the Rends. Mr. Patrick has been in the coal business for a number of years, having represented Moderwell & Co. in northern Illinois before that concern sold out to the Old Ben Coal Corporation.

Obituary

Charles Albert Bowman, aged 40, superintendent of the Lincoln Highway Coal Co., died Feb. 11, of pneumonia, at his home in Pittsburgh, Penn.

W. P. W. Haff, a well known coal man, with offices at 1 Broadway, New York, N. Y., died in Los Angeles, Cal., Feb. 23. Mr. Haff went to California for his health in December last and was thought to be improving. His home was in Freeport, L. I.

Charles H. Zeller, aged 47, for many years an operator in the block coal and bituminous fields in the vicinity of Brazil, Ind.,

died Jan. 30 of a complication of diseases. He was the son of John H. Zeller, one of the early and most successful operators in the block coal field.

M. J. Murray, Sr., coal operator and banker, of Dunmore, Penn., died at his home on Feb. 26, after an illness of several months duration. Mr. Murray was born in Ireland Mar. 10, 1846, and came to Dunmore at the age of 7. For many years Mr. Murray operated a colliery at Dunmore, and in 1905 leased 464 acres at Bernice, Sullivan, and organized the Northern Anthracite Coal Co. Mr. Murray was interested in several banking institutions, coal properties and other industries.

Samuel Gillies, president of Gillies-Guy, limited, Hamilton, Canada, died in St. Petersburg, Fla., on Feb. 22, aged 78. The company was one of the largest distributors of coal, both bituminous and anthracite, in Canada. It had been established by Mr. Gillies in 1906, who had formerly been in the lumber trade in Saginaw, Mich. He had been one of the leading citizens of Hamilton, but of late years had been out of health. He leaves a widow and three sons, David H., in the coal business at London, Canada, and Samuel R. and John W. Gillies, in business with the father.

Sir Guy Spencer Calthrop, comptroller of English coal mines since 1917, died on Sunday, Feb. 23, in London, England, of influenza. Sir Guy, who was created a baronet in 1918, was born in 1870 in Uppingham, Rutland, and was a nephew of the late Viscount Alverstone, and was general manager of the London & Northwestern Ry. He was general manager of the Caledonian Ry. in 1908, and general manager of the Buenos Aires & Pacific Ry. in 1910. In February, 1914, Sir Frank Lee, the general manager of the Northwestern, died, and Guy Calthrop, then aged 41, was appointed to fill the vacancy, the youngest man who had ever controlled the line.

Trade Catalogs

Green's Economizers.—The Green Fuel Economizer Co., Beacon, N. Y. Bulletin No. 151. Pp. 63, 8½ x 11 in., illustrated. A summary of the facts regarding Green's improved patented fuel economizer.

Local Battery Telephones. Stromberg-Carlson Telephone Manufacturing Co., Rochester, N. Y. Bulletin No. 1024. Pp. 22; 7¾ x 10 in.; illustrated. Contains complete information about the company's wall telephones.

Repair of the German Ships. Wilson Welder and Metals Co., Inc., New York, N. Y. Tells how the wrecked machinery on the German ships lying in American ports was repaired by electric welding with the aid of the Wilson-Plastic-Arc welder.

"C. J." Coal Meter. C. J. Manufacturing Co., Philadelphia, Penn. Folder. Pp. 6, 4 x 9 in., illustrated. Describes the uses and system of operation of a coal meter that can be used on any underfeed stoker having an accessible revolving shaft.

Hercules Products. Hercules Powder Co. Catalog. Pp. 144, 6 x 9 in., illustrated. Book will prove valuable to users and prospective users of explosives. It contains a general description of products manufactured and marketed by the Hercules Powder Co.

A Chain of Evidence. Morse Chain Co., Ithaca, N. Y. Publication No. 16—"Small Power Drives." Pp. 24, 6 x 9 in., illustrated. Enumerates the advantages of Morse chain drives. Illustrated by many photographs of actual applications of medium power drives.

Modern Methods of Ash Disposal. American Steam Conveyor Corporation, Chicago and New York. Catalog. Pp. 160; 7¾ x 10½ in.; illustrated. A presentation of the most economical and efficient methods of moving ashes, soot and combustion waste from boiler room to disposal station.

The Art of Jigging Coal.—G. H. Elmore, Philadelphia, Penn. Bulletin. Illustrated, pp. 13, 8 x 11 in. One of a series of bulletins describing the Elmore jigs. This bulletin concerns the washing of bituminous coal for fuel with Elmore 600-A jigging machines equipped with automatic refuse control.

The Jeffrey Pivoted Bucket Carrier. Jeffrey Manufacturing Co., Columbus, Ohio. Catalog No. 210. Pp. 96; 6 x 9¼ in.; illustrated. Gives details of the carrier and illustrates large power plant equipment. A feature of the catalog is the reproduction of dimensioned blueprints in actual color of typical views for the various sizes of carrier equipment.

Ingersoll-Rand High Speed-Piston Valve Steam Engine, Class FD. Form 9026. Pp. 12, 6 x 9 in., illustrated. Engine is of the horizontal center-crank type, and the steam valve is of the most approved design, permitting the use of the highest steam pressures and superheated steam. Catalog contains cross-sectional illustrations showing the machine in detail.

Geared Marine Steam Turbines. De Laval Steam Turbine Co., Trenton, N. J. Bulletin M. Pp. 32, 8½ x 11 in., illustrated. New publication describing the details of construction of turbines and gears and also various turbine-driven auxiliaries, including lighting sets, circulating pumps, boiler feeders, etc. A new development is the centrifugal pump for the continuous purification of the oil used in the turbine and gear bearings and on the gear teeth.

Industrial News

Auburn, N. Y.—The Columbian Rope Co., manufacturer of Cordage, has issued an attractive poster, in colors, showing the lowering of a lifeboat at sea. The poster is suitable for hanging.

Uhrielville, Ohio—The Walnut Coal Co. has been incorporated with a capital of $10,000 by John W. Lindsay, Archie Stevenson, Freeman Wilkinson, Anna V. Lindsay and Matilda Stevenson.

Cincinnati, Ohio—The Walter-Wallingford Coal Co. has been chartered with a capital of $100,000 by L. F. Walter, B. A. Wallingford, C. S. B. Ward, Samuel H. Whitaker and A. J. McCarthy.

Terre Haute, Ind.—The Vicksburg Coal Mining Co. has been incorporated here with stock of $30,000. The directors for the first year are Horace W. Robertson, Walter Robertson, William H. Kivits and Albert F. Kivits.

Columbus, Ohio—The Mount Cherry Coal Co. has been incorporated with a capital of $600,000 to mine and sell coal. The incorpators are Warren B. Ferris, Herman Eckhardt, Thomas M. Hardesty, Henry J. Mayer and Ernest H. Whiting.

Minneapolis, Minn.—The Reliance Coal Co., of Minneapolis, has obtained the exclusive agency in the Northwest for the Columbus Mining Co.'s "Lafayette" and "Columbus" coals from southeastern Kentucky. It is estimated that the deal will involve about 75,000 tons of coal per year.

Cincinnati, Ohio—The Dickinson Fuel Co., which operate mines in West Virginia, is preparing to enter this territory as a distributor and will construct distributing yards and hoppers at points to be selected on the Chesapeake & Ohio and Norfolk & Western railroads, on both of which it has mines.

Pittsburg, Ky.—W. R. Grant, Pittsburg, has recently completed negotiations for the leasing of approximately 450 acres of coal properties in the vicinity of High Splint, Ky., and is understood to be arranging plans for early development. The property is held by the Cooper Ridge Coal Co., of Evarts, which recently increased its capital to $75,000.

Youngstown, Ohio.—In its annual report to stockholders, it is interesting to note that the Youngstown Sheet and Tube Co has invested a total of about $2,500,000 in the development of its coal properties in Greene County, Pennsylvania. The mine, which fronts on the Monongahela River, has a capacity of about 450 tons daily. James A. Campbell is president.

Ithaca, N. Y.—The Morse Chain Co. announces that it is advised by P. A. Morse, of the Morse Engineering Co., western representatives, St. Louis, Mo., that the Kansas City offices have been removed from the old quarters in the R. A. Long Building, to more commodious rooms, Suite 211-212, Finance Building. W. V. Warner is the office district manager.

Panama, Okla.—The Buck Creek Coal Co. has been organized here, with a capital stock of $15,000, and charter has been filed with the Secretary of State at Oklahoma City. The incorporators are A. W. Breckenridge, of McAlester; Thomas L. Tatum, of Milton; and William T. Harper, of Fort Smith, Ark. The company will develop its coal lands in eastern Oklahoma.

Mobile, Ala.—During the past week a number of boats loaded with steam or bunker coal at Mobile, the fuel being sent by rail and Warrior River barges from the Birmingham district, to supply the demand for the service between Mobile, Cuba and South America. The Louisville & Nashville R.R. has put in a coal-loading device on the Mobile water front, and is prepared to handle almost any amount of coal for the ocean-going steamers.

Charleston, W. Va.—A coal-carrying railroad will top certain coal lands in Greenbrier County, the new road to be known as the Greenbrier & Eastern. It is to be financed by Charleston people who are interested in the coal properties which the railroad will make it possible to operate. The company will have an authorized capital of $50,000. It was organized by B. B. Brown, Angus W. McDonald, O. P. Fitzgerald and L. G. Cunningham, all of Charleston.

Birmingham, Ala.—Coal production for the Birmingham district during the week ending Feb. 15 was 281,284 tons, according to reports turned in at the Alabama Coal Operators' Association. The final report of production for the previous week was 274,442 tons. Coal production for the past two weeks is more than 100,000 tons below the estimates made by experienced coal men. The reduction in output, according to operators, is due to labor shortage and lack of market.

Cincinnati, Ohio—Executive committee of the recently organized Central Coal Association, comprising coal operators in West Virginia, Kentucky and Ohio, has selected as the secretary of the organization Guy M. Freer, for several years manager of the traffic department of the Cincinnati Chamber of Commerce, and a man especially well posted on the problems of the coal trade in this section, especially in the matter of transportation. The offices will be located in Cincinnati in charge of Mr. Freer, who will give all of his time to the work.

Canton, Ohio—C. A. McDonald, president of the Canton Coal Co., has been elected president of the Central Ohio Coal Operators' Association at the annual meeting of the board of directors held recently. He succeeds E. E. Fox, an official of the Goshen Coal Co., Massillon, who has been president of the association for a number of years. John Kite, vice president of the Midvale-Goshen Coal Co., Massillon, was elected vice president, and William H. Haskins, commissioner, was reëlected secretary and treasurer. The headquarters have been moved to Canton.

Louisville, Ky.—Figures relative to coal consumed in Louisville during the year 1918 show that a total of 1,618,021 tons of rail coal came into the city, 89,046 tons of river coal and 4928 tons of anthracite, the latter during the first six months of the year. This makes a total of 1,707,067 tons of bituminous, and a total of 1,711,995 for all grades. These figures show an increase of 1,600,000 tons over the previous two-year average of the Fuel Administration. Kentucky is figured on for 5,600,000 to 5,700,000 tons annually. Some river coal was delivered during each of the ten latter months of 1918, the first two months finding the river blocked with ice.

Charleston, W. Va.—Only one measure affecting the coal industry of the state in addition to the Hale bill reorganizing the Department of Mines was finally acted upon by both houses of the West Virginia Legislature, and that was the Lewis bill. This bill amended Section 17 of Chapter 15ll of the Code. The clause amended read: "And in no case shall more than ten persons ride on any cage or car at one time," the section covering shaft, slope and incline mines. The clause as amended reads: "And in no case where the mine is operated or worked by shaft or slope shall more than ten persons ride in any cage or car at one time," the effect of the amendment being to exempt incline mines from the application of the provision covering the number of persons permitted to ride on a car or cage.

Louisville, Ky.—Kelly C. Cornelius, assistant treasurer of the Liberty Coal and Coke Co., with mines at Straight Creek, Wallshend and Easley, Ky., has opened a new sales office at Room 407 Louisville Trust Building. Mr. Cornelius reports that production will be increased this summer, and that the company is adding to its land holdings in the Straight Creek neighborhood. This company was formerly a part of the old Continental Coal Co., which was disorganized, and the properties taken over by two operating companies, the Knoxville faction operating as the Federal Coal Co. The Liberty company has a large battery of coke ovens, but is not producing any coke at the present time. It now has a daily production of 900 tons, and good selling facilities, making it possible to operate full time. Much of its output is going to Federal cantonments at Camp Jackson, Fort Oglethorpe and Camp Gordon, the latter taking 900 tons daily.

MARKET DEPARTMENT

Weekly Review

Industry Shows Signs of Improvement—Inquiries Being Made for Next Year's Requirements—Bituminous Output Still Decreasing—Prices Maintained—Reasons Why Anthracite Coal Prices Will Not Be Lowered

INDUSTRY is beginning to sit up and take notice. Instead of going to the "demnition bow-wows," as was freely predicted by some cocksure prophets (?) only a few short months ago, Uncle Sam has really turned the corner and before long will be striding rapidly down the wide avenue labeled "Prosperity."

The greatest export business in the history of the United States was done during the month of January. We shipped from our ports in the first month of the present year goods to the value of $623,000,000. This is $57,000,000 better than the export business we did in December of last year and is an increase of $118,000,000 over our foreign business in January, 1918. (Surely this in itself should serve as a refutation of the pessimistic utterances of the calamity howlers!) The steel industry, which is said to be a barometer of business conditions in the country generally, is operating at more than 75 per cent. of capacity. The tin mills are doing even better.

What all this means to the bituminous coal industry is self-evident. Since the signing of the armistice manufacturers in the main have been burning fuel from their stock piles. In spite of curtailments, suspensions, and the shutting down of many industrial plants, a great tonnage of coal was consumed during the past four months. Reserve stocks in the majority of cases are dangerously low, and purchasing agents who have kept out of the market for obvious reasons are now making inquiries. True, there is no pronounced buying movement or contracting activity manifest as yet; but the rippling of the surface shows that the fish are in the depths below, ready to rise to the bait.

Prices of bituminous coal are being maintained firmly, with the exception that off-grade coals are being quoted at considerable reductions to keep them moving and avoid the payment of demurrage charges. It is rumored that there will be a further increase in price of some of the high-grade bituminous coals in the near future. Output is declining, due to half-time operation at most of the mines. This helps to steady the market and really should be a source of worry to consumers with scanty stocks. But as to that, time alone will tell. Only 7,696,000 net tons of soft coal were produced during the week ended Feb. 22, which brings the total output for the coal year to date to 517,479,000 net tons, 23,737,000 net tons in excess of production for the same period last year.

From a number of quarters comes the information that the prices of anthracite coal will surely decline. On what grounds this belief is based it is difficult to see. Nothing, in fact, is more improbable. Not only will the prices of the domestic sizes of hard coal *not* decline, but they are due for an increase. Householders would do well to profit by this warning.

Here are a few of the reasons why the price of the prepared, or domestic, sizes of anthracite will not be lowered: (1) The cost data compiled by the Fuel Administration and recently made public show that 60 per cent. of the anthracite mines were not making any money at the fixed Government maximums. Price control has been removed. These operators, in order to stay in business, will have to raise their prices; otherwise they are faced with the prospect of bankruptcy. (2) To send prepared sizes of anthracite to market it is necessary that the mines screen their coal. Unless the small sizes that result can find a market, the screening of domestic sizes must stop; or else the prepared coal must command a price that will permit of the sale of the small steam sizes in competition with the steam sizes of bituminous coal, which are much cheaper. (3) The present wage agreement in the anthracite field automatically expires with the signing of the peace treaty. The wage scale that would then be in effect is lower than the so-called war scale now ruling. Are the miners going to accept a reduction in wages? (4) The harbor workers at New York are on strike for a shorter workday and an increase in wages. Any of the demands granted will mean an added charge for lighterage and the towage of coal barges. This added cost will be passed on to the consumer.

These are only a few of the signposts that point the way to higher coal prices. It may be that the increase will be postponed until the treaty of peace is actually signed, to enable the operators to refuse any demands for higher wages at this time. But that higher coal prices will come is certain. Every indication points to a raise month by month, as a seasonal differential, until a certain maximum is reached.

WEEKLY COAL PRODUCTION

Bituminous—The production of bituminous coal during the week ended Feb. 22 is estimated at 7,696,000 net tons, and is a slight decrease compared with the week preceding, and a decrease of 3,420,000 net tons compared with the week of Feb. 22, 1918. In previous years the occurrence of Washington's Birthday, like all other holidays, was quite a limiting factor in the production of bituminous coal; but with the lack of demand at this time, the observance of the holiday had practically no effect on the week's output. The average production per working day, estimated at 1,283,000 net tons, not only fell below that of the preceding week and corresponding week of 1918, but also fell considerably below the daily average for the coal year to date, estimated at 1,835,000 net tons, and the daily average for a similar period of last year, estimated at 1,751,000 net tons. For the coal year to date, production of bituminous coal now totals to 517,479,000 net tons and is in excess of the production for the same period of last year by 23,737,000 net tons.

Anthracite—Practically no change occurred in the production of anthracite during the week ended Feb. 22, the output being estimated at 1,113,000 net tons, but 13,000 net tons in excess of the output of the week of Feb. 15. Compared with the corresponding week of 1918, the current week's output is extremely low, falling 741,000 net tons behind. The daily average per working day during the week of Feb. 22 is estimated at 186,000 net tons, as compared with 305,000 net tons during the coal year to date and 316,000 net tons for the same period of 1918. The total production from Apr. 1, 1918, to Feb. 22, 1919, is estimated at 86,020,000 net tons as against 89,238,000 net tons for the period Apr. 1, 1917, to Feb. 22, 1918.

Coal Loading—Reports received from carriers show that the decrease in loading during the week ended Feb. 22 occurred in Alabama and in the central and far western states. Slight increases occurred in all other fields. For the calendar year to date, coal loading is far behind that of last year in all districts, with the exception of Fairmont, where the present year's loading is slightly in excess.

Bituminous Shipments—Shipments of bituminous coal to New England during the week ended Feb. 22 are estimated at 245,231 net tons, and are slightly in excess of shipments during the week preceding. The receipts through the rail gateways during the week are estimated at 102,584 net tons, and are a decrease of 16,456 net tons compared with the week of Feb. 15, while the shipments to New England by tidewater exceeded the tonnage of the preceding week by 20,716 net tons.

Shipments from the North Atlantic harbors and Hampton Roads to all points for the week ended Feb. 22 are estimated at 592,497 net tons, as compared with 526,085 net tons during the week ended Feb. 15. Increases occurred in the shipments from New York, Philadelphia and Hampton Roads, while Baltimore tonnage decreased. At the present time the weekly shipments are but 72 per cent. of the average for the coal year to date.

Beehive Coke—The production of beehive coke in the United States during the week ended Feb. 22 is estimated at 445,700 net tons. This output exceeds that of the week preceding by 24,024 net tons and falls behind the output of the corresponding week of last year by 128,286 net tons. The daily average during the current week is estimated at 74,283 net tons, as compared with 70,279 net tons during the week preceding and 95,664 net tons during the week of Feb. 22, 1918. For the calendar year to date the production of beehive coke is estimated at 3,901,382 net tons, and is a decrease of 145,730 net tons compared with the same period of 1918.

State production figures are now available for the first time, and bring to light the fact that Pennsylvania is the lone state producing beehive coke, for the calendar year to date, in excess of the output for the same period of last year. During the current week, production in all states fell behind that of the same week of 1918. The output of the operators in Pennsylvania, West Virginia, Virginia and Kentucky exceeded that of Feb. 15, while all other states report a decrease.

BUSINESS OPINIONS

Bradstreet's—While the trade and industrial pace is still of a cautious, in some sections, indeed, an even slow, character, evidences of moderate improvement in distribution are now too numerous to be denied. Certain it is that, compared with a month ago, there are fewer poor reports, and a résumé of both wholesale and retail trade, of industrial conditions and of collections reveals the general trend to be rather above than below fair.

Dry Goods Economist—To judge from the number of buyers who have visited the New York market in search of supplies for dry goods and department stores, the business of the country has apparently suffered no reduction. On every hand the report is heard business is good. Labor unrest continues in various fields of industry. The strike of the operatives in New York garment manufacturing plants continues but is no longer considered important. Strikes started this week in shoe factories of New York where operatives have made a demand for an eight-hour day. In other centers nothing of importance has developed to affect the production of textiles.

American Wool and Cotton Reporter—Choice wools, particularly the kind wanted by the worsted mills, are scarce. The woolen mills seem to have more business ahead, and it is intimated that there is a possibility that the worsted mills may also, but not very much is being said about the business of the latter. The great effort being made to cut down the acreage planted to cotton may have some effect, but it never has been of any great importance in the past and it may not be at the present. If any real important result is attained it will seriously affect the wool. The price of cotton will not advance much until conditions change, although there ought not to be any great decline so long as holders are unwilling to dispose of cotton at prices lower than those noted at present.

Dun's—For the waiting policy of buyers, whose potential needs are heavy, the explanation lies chiefly in the price question, but even after many weeks of market defla-

tion, embracing a considerable range of commodities and in some instances of a drastic nature, demand continues hesitant. As a natural outcome of this condition, manufacturing in most lines, and notably in the leading Eastern centers, has receded materially from the extraordinary rate of the war period, and diminution of consumers' purchasing power through elimination of overtime work and increasing unemployment is an influence in retail circles. Yet there are various bright spots apparent, including the strong financial position and the exceptionally light commercial mortality, and sentiment reflects growing optimism as the Spring season, with its promise of enlarging outdoor activities, approaches.

The Iron Age—Current demands for mill products have been larger in the aggregate than commonly appreciated. Those plants which have had to shut down outright or run in alternate weeks have worked off the back log of accumulated orders and others, even where 65 per cent of capacity is engaged, are now almost wholly on new bookings, which keep three to eight weeks' work ahead of the mills. It is those mills which are equipped more particularly to turn out railroad material or are not adapted to supplying the automotive trade which emphasize the light volume of buying. Stocks in hands of producers are low, but distribution has not been affected by manufacturing consumers, notably the agricultural implement makers. Heavy buying is therefore not to be expected in the immediate future from such sources and it is argued that this distribution should not be embarrassed by injecting into it drastic price-cutting questions.

Atlantic Seaboard

BOSTON

Market continues without noticeable change. Inquiry scattering and for small tonnages. Tidewater situation shows no improvement. Uneven prices and lack of buying interest. Higher grades from Pennsylvania held at recent Government figure. Buyers discriminate between grades. Season for legislative "remedies." Room for much adjustment. Water freights easier on certain kinds of barge transportation. Anthracite dull. Only listless demand for domestic sizes. Wide variation in retail prices. Dealers troubled over uncertain outlook.

Bituminous—The present situation in New England has more the characteristics of "midsummer dullness" than any month of March in the history of the trade. All the larger consumers, railroads and other utilities included, continue to have a surfeit of coal on hand, and the much hoped-for "active market" seems as far away as ever. There are no significant developments; things just keep mulling on with light traffic and minimum consumption in almost every direction. Only small inroads are being made in the heavy stocks accumulated under the stress of war emergency, and the movement both all-rail and by water is still in very small volume. The shippers have become reconciled to meager business and buyers are still being canvassed closely, although quotations are now on a better established basis than was the case a month ago. There is still no railroad policy with respect to new purchases, and naturally there is apparent among the roads in this territory a distinct effort to reduce their fuel reserves, before undertaking anything like comprehensive buying.

Among small buyers there is now a scattering demand, but it takes careful combing to uncover it. It is almost wholly confined to those whose storage was small or those who were unable last fall to get forward what was required for early spring consumption. The aggregate of these small current purchases is considerable, and when added to shipments coming forward on contract accounts for the present all-rail movement which, in proportion, is in much better volume than are deliveries by water. With the present wide differential in favor of rail shipment it is plain that deliveries inland from tidewater rehandling plants are being held down to an absolute minimum.

Little is heard as to contracts. One or two of the Hampton Roads factors have had some success in tying up a certain tonnage on a mine price "plus" basis, but when entered into either by consumers or retail dealers such arrangements are usually based upon good service in recent years rather than upon any commercial advantage as yet disclosed. The current market shows no improvement whatever, and there are still cargoes of "distress coal," overshipments on old contracts, etc., to be absorbed by an already overstocked market. Frequently there are instances where cargoes shipped in exact compliance with contract are obliged to wait discharge until current consumption makes room for the coal to be added to storage. Scores of mines are idle in the smokeless districts, and there are few agencies that are not under embargo because of failure to dump at Hampton Roads piers the accumulations now standing to their order.

Producers of the better grades from Pennsylvania show every intention of holding to the recent Government price level of $2.95 per net ton, except in a few cases where the coal is held at figures slightly higher. Many of the operations are down to 25 per cent. or even 10 per cent. of normal output, but there have been fewer instances lately of any shading in prices, except on inferior grades; $2.15@2.40 per net ton is still the range on some of the higher volatiles.

Certainly there is every indication that when comprehensive buying does start in there will be a good deal of discrimination between the grades offering. Large tonnages that were placed here last year through Fuel Administration channels were of inferior grades and the experience is lasting so long that buyers have become well schooled in the disadvantages of poor quality. It is this deep-rooted feeling on the part of so many buyers that makes it possible for a considerable tonnage of Pocahontas and New River to be absorbed on contracts in the face of the much lower quotations that are made on certain Pennsylvania coals that are offered for all-rail shipment.

While the United States Shipping Board has in no wise modified the mandatory rate on requisitioned steamers, there are abundant signs of weakening in such water rates as are not regulated through any Government channel. On Long Island Sound there is now a large surplus of barges and rates have receded very nearly $1 a ton from those recommended a short three months ago. In other words, freights from New York to points like Fall River and New Bedford are $1.10@1.25, instead of $2@2.15. Meanwhile, railroad-owned barges are being held at $1.75 on anthracite between the same ports, and no sign of change. Of course, the few buyers who are taking coal are using outside privately owned transportation.

Anthracite—Retail dealers are having difficulty in shutting off shipments, and one result is a generally overstocked market. The exceptional winter has made a big difference in winter deliveries and the system of anthracite "applications" devised by the fuel authorities only added to the generally mistaken estimates that were made early in the season. Domestic sizes are only in listless demand. A few retailers are quietly accepting what deliveries are made them, partly on the ground that prices will not be reduced, but these are in the minority. Most of the dealers along the coast are expecting at least a reduction in water freights and there will be no active spring buying until the outlook is somewhat clearer and less uncertain than at present.

There is a noticeably uneven retail price line throughout New England, not always following the differences in cost. The range is from $11 in Boston to $14 in Lewiston, Me., and there are similar wide variations within relatively short distances. Naturally the public finds it difficult to reconcile such figures and it is hoped that many needed adjustments can soon be made.

NEW YORK

Consumers await operators' announcement regarding summer prices. Usual reduction will mean good business. Demand for domestic coals continues slow. Tidewater dumpings show decrease. Anthracite steam coals stronger. Bituminous market shows improvement. Embargoes are declared off and docks are well cleared of surplus. Troubles reported in New River and Pocahontas fields.

Anthracite—In addition to small consumption the failure of the coal producing interests to make public their intentions as to what might be expected by consumers on Apr. 1 in regard to prices is having its effect upon the situation. The question of spring and summer prices is one of paramount interest to all users of hard coal, but particularly to New Yorkers. Many who heat their own homes like to know that their next winter's fuel is safely stored away in the cellar before they leave the city for the summer. Failure of the operators to make a reduction in the present prices will likely result in a comparatively small wholesale and retail trade here during the summer, many householders believing they might as well wait until the fall and take chances of getting coal.

It was expected that some announcement might be forthcoming from the operators after their meeting in Philadelphia on Friday last (Feb. 28), but it is understood that no conclusion was arrived at by those in attendance.

The demand for domestic sizes continues to be small, but a better situation exists in the steam coal market, due to the suspension of operations at the mines, resulting in a smaller production of buckwheat, rice and barley coals.

If production is maintained on practically the same basis as it was during the month just closed, the situation will be in a comparatively easy condition on Apr. 1. There is a slow but steady call on the retail trade and just about enough to enable the dealers to begin the coal year with ordinary stocks. Just now no dealer is willing to take in more than he is likely to require with the spring situation uncertain.

Reports of cars dumped during the week and month ending Feb. 28 show a big slump. In the first instance there were 2962 cars emptied as compared with 3732 cars the previous week, a decrease of 770 cars. For the entire month there were 15,137 cars dumped as against 23,756 cars during January, a decrease of 8619 cars.

Wholesale dealers report little business coming from Canada. Stocks are reported as large, and there is little demand. Heavy stocks are also reported in the West and inquiries for business bring the information that only real bargains will be considered.

There is little doing here with regard to the domestic coals. The companies are maintaining their regular schedule of prices while so-called independent coals have been held at 20c. below. Pea coal moves slowly and quotations range from $4.65 to $4.80 at the mine.

There is a stronger feeling in the anthracite steam coals, owing to the slow production. Buckwheat No. 1 was quoted at from $2.75 to $3.25 at the mines; rice from $2.35 to $2.40, and barley from $1.50 to $1.80, all for the better grades. Inferior coals were, it was said, being quoted at about 30c. lower, principally for loaded boats.

The local anthracite situation is not very encouraging. There is some chestnut, stove and egg moving in, but this is nearly all going into storage. The domestic demand is light. The country business on chestnut is fairly good.

It is generally understood here that effective the first of April there will be an increase in the price of anthracite coal.

Bituminous—The situation shows much improvement. The docks are in much better shape and there is not a large amount of surplus coal on hand. There has been a much heavier demand for bituminous than for anthracite, as is noticeable in the report of the Regional Director of Railroads of cars dumped during the week ended Feb. 28. The reports show that 5017 cars were turned over as against 6248 cars the week previous, a decrease of 1231 cars. For the month of February there were 23,668 cars dumped as against 23,769 cars in January, a decrease of 101 cars.

Wholesale dealers report a much better condition of affairs, but there is said to be some coal which has been offered much below the Government maximum in order to save demurrage charges. Even at that it is not always an easy matter to dispose of it, most consumers having large stocks in their yards and no desire to add to them.

It is not expected that many shippers will take advantage of the Fuel Administration order and do business independently of the Tidewater Coal Exchange.

Western sales agents writing to local houses say there is abundant coal in the West and that demand is slow with no prospects of better business for several weeks.

There is a strong feeling that operators in the New River and Pocahontas fields are facing labor trouble which may resolve itself into a suspension of operations, or possibly a strike, by Apr. 1. Reports received here are that some producers have sub-leased storage plants and are storing coal in anticipation of trouble. Coupled with this report was another to the effect that prices for these two grades of coal would soon be boosted, probably as much as 75c.

Locally conditions are much stronger. There is not so much free coal around and not so many loaded boats. Distributors are not sending their product to Tidewater unless there is a buyer in sight, and this helps conditions considerably.

Consumers who buy all-rail coal are particular now as to what grade is sent them and are paying nearly the Government maximum.

Quotations at Tidewater vary greatly, much depending upon the pool wanted. Coals in Pool No. 9 were being quoted the early part of the week at from $5.85 to $6, and from Pool No. 10 at from $5.35 to $5.50.

PHILADELPHIA

Anthracite trade unsatisfactory. No real improvement in sight for a month. Buying both wholesale and retail at low ebb. Some individual price-cutting. Mines on half-time, with production difficult to move. Some slowing up of accounts. Retailers getting ready for spring trade. Retail price-cutters more active. Mine labor restless. Stove and nut in chief demand. Steam coal quiet, with fair outlook for future. Bituminous still draggy. Prices fairly well maintained. Good bunker business.

Anthracite—Philadelphia coal dealers are a disgruntled lot and are gradually losing respect for their business. The month of February was such a distinct disappointment that they have little hope of any improvement during March, and indeed some of them say they do not even look for normal conditions before next fall. The representative dealers show much concern for the future, as they claim that unless some drastic action is taken to force the public to believe that there can be no sharp decline in prices there will be all kinds of trouble next fall and winter. Many householders appear to believe that prices will be lowered several dollars a ton, and we have recently actually heard the dealers called upon to deliver in one-half-ton lots.

The individuals are cutting prices; there is no doubt about that, but it is difficult to judge just how low they will quote. Often a shipper has coal standing at the scales on demurrage and after several days is forced to let go at a ridiculous price. The dealer who buys it will sometimes try to drive a bargain with another operator and quote this price. Such sales form false impressions and of course should not be taken as a basis for estimating current conditions.

We have heard some strange names for coal lately, and it is just possible that some of the smaller houses are for the time being renaming their collieries when making these low prices for quick sales in order to avoid cheapening the reputation of their product. Every house has every available man on the street, and some of them seem to be adopting the method of calling by telephone every possible prospect two and three times a week. Notwithstanding all this effort it must be admitted that sales are few and not substantial. It is with difficulty that the most reputable mines can be worked more than three days a week. One famous coal that for years has been sold at a premium has this week been freely offered at company circular.

As to payments the companies are not complaining about their accounts, but feel they are no longer to enjoy the prompt payments of last year. They claim it is noticeable that the January balances are larger than for many months. Like the retailer, if the shipper forces sales, he soon finds he has a list of slow accounts.

In the suburban districts where the houses are larger and the people more affluent business usually holds up better than in the city proper. Here we also found the dealers complaining and delivering little coal. They, too, are laying off men and selling horses to reduce expenses.

Another price-cutter appeared in the retail trade this week much to the disgust of the representative dealers who have so earnestly tried to influence their competitors to maintain their full rates based on the $2.50 margin allowed when Mr. Lewis local administrator, was in office. The lowest rates now being advertised are egg, $10; stove, $10.25; chestnut, $10.25; pea, $8.25. This is a reduction from the standard prices of 30c. on egg, 35c. on stove, 40c. on chestnut and 80c. on pea.

Some of the larger dealers are considering seeking legislation to reduce the weight of a ton of anthracite in this state from 2240 lb. to 2000 lb. As the legislature is now in session there is no doubt that a bill will be presented. The dealers claim that with the gross ton for anthracite in this State they are placed at a disadvantage when prices are compared with sales in states on the 2000-lb. ton.

Many reports are heard from the mining region about the discontent among the miners because of the short working time. At a recent meeting of union men in the region the statement was made and printed in the newspapers that the operators were cutting down the working time simply to uphold the prices. Of course any one connected with the trade knows how ridiculous a statement this is. One local even went so far as to petition Congress to take over the mines and work them full time. There can be no denying that mine labor is extremely restless, and it is reported that the operators have held a meeting to consider this phase of the situation.

Shippers report the sales of the past week to have been confined chiefly to stove and chestnut. A light tonnage of egg is coming here and practically no pea coal, as some dealers have enough of this latter size to run them for several months; while the average retailer has more than he ever had at this time of the year. The demand upon the dealers for this size appears to be over for the season, although it is thought March may bring business in small lots to finish out the month.

The steam coal prices do not seem to indicate it, but report has it that the small sizes are due for a brace. Stocks are being cleaned up to some extent and some industrial plants which had coal stored, it is expected, will again be in the market before long. Upon inquiry we hear of buckwheat for $2.60 to $2.75, on up to company circular of $3.40. Rice is around $2 and barley dragging along around $1.25.

Bituminous—There is no marked change in the soft-coal situation. All operators continue to work on reduced time and seem simply to be in a waiting mood for the better times which are forecasted. Shippers almost generally insist upon the full price for the good coals, and while some grades can be purchased off price, the sales are not such as to break down the market for the good coals.

At tide there is fair business, especially in bunkering, which is calling for the very best grades. Recently we heard of quite a piece of business for bunker fuel closed at a good figure.

BALTIMORE

Export movement fails to respond in way that December shipments had promised. Soft-coal market over-supplied, but steadier under sale reservations. Hard coal selling lacks interest.

Bituminous—A disappointing feature of the present market, when the supply of soft coal so far exceeds the demand, is the failure of the export trade to materialize. After the first eleven months of 1918 had seen a movement of less than 7000 tons per month for foreign account, December saw a jump and more than 30,000 tons was loaded for foreign delivery. Lack of bottoms, labor disturbances at consuming points, freight rates, etc., however, caused a halt and the January and February movement has been a disappointment to those who had hoped for a decided revival. The foreign bunker business, which during 1918 averaged around 20,000 tons per month, is holding up fairly well, however.

While the run of soft coal to the piers and other points in this district is still in excess of urgent needs, a steadying influence has entered the trading. A producing company handling specialized coal the past week let it be known that none of the particular product would be released below $3.20 net, or about 45c. above the old Government maximum. This news at once strengthened a number of other better coals. Even where there was over-supply here the better fuels were being held pretty firmly at the old Government maximum. Poor coals and gas coals, however, continued to sell much off those figures. The shipment of some coals outside the pool here has begun, although the greater amount of movement is still through the Tidewater Exchange and likely to remain in that channel. The end of the no-reconsignment order also proved pleasing to the trade here.

Anthracite—Little interest is manifested here in the hard coal market. The mild weather still holds and buying keeps up only in ton and half-ton lots for the most part. The main feature of interest to the trade the past week was a banquet given by the retail exchange to the Maryland Fuel Administrator, Ferdinand A. Meyer, and his staff, at the Southern Hotel, on the evening before their official termination of duties with the Fuel Administration, Mar. 1. The first real awakening of interest here will come with the discussion of possible spring schedules—if there turns out to be such a "beastie."

Lake Markets

PITTSBURGH

Stocks still in evidence. Hardly any buying. Production 25 to 30 per cent. of capacity.

Stocks of coal in the hands of consumers have not decreased enough to bring any additional demand into the market, and in consequence the market remains extremely dormant. Shipments of coal are at 25 to 30 per cent. of the mine capacity in the district, and are confined almost entirely to quantity. Less coal is being forced on the market through being loaded and having to be sold at almost any price to avoid demurrage charges, and in this respect the market is on a firmer basis than formerly.

The byproduct coke ovens are operating fairly well and are consuming almost as much coal as formerly. The steel mill consumption of coal is somewhat less, but it is still at a very good rate. Production of steel is at 15 to 20 per cent. less than at the maximum, late last fall. From the coal standpoint the chief difficulty about the steel industry is that it is using up stocks. Railroad consumption of coal is distinctly less. Outlook for the lake shipping season is not particularly good and it seems probable that shipments will be light early in the season, though by midsummer they may be at full rate.

There has been no negotiating as to contracts for the lake season, buyers preferring to hold off. Operators are equally in a waiting mood as to all classes of sales and show no disposition to force an issue. From present appearances it is quite within reason to expect that coal prices will be fairly well maintained, sellers merely waiting until buyers are willing to pay the price. The market at the moment is not closely quotable, as the grade of coal has so much influence upon prices. Generally speaking the market, outside of odd lots of demurrage coal, may be quoted at $2.25@2.35 for mine-run steam coal and at $2.50@2.70 for ¾-in. gas coal, per net ton at mine, Pittsburgh district.

BUFFALO

Little change in the situation. Bituminous possibly a trifle stronger. Trade hopeful, but nothing certain. Mines running at a slow rate. Anthracite accumulating.

Bituminous—Demand is still light, but stocks are running down and more will have to be bought before long or the industries will suffer. It is an odd situation. The consumers of all sorts of goods are waiting for prices to come down, while the producer and labor are engaged in holding them up. Not much can be done till this struggle is over.

Jobbers do not see any trade for them right away. They are waiting about as they were with just trade enough to keep them from utter despair. They do not fear complete annihilation, as some of them did when the Government fuel administrator was after them, for some day normal conditions will come back and then they will be wanted. They have won one battle in the dropping of the rule not to reconsign cars, but the benefit will not be evident right away. As a section Buffalo is apparently faring about as others are. It is a waiting market and must remain so till the industries move normally.

Former bituminous prices are held pretty tenaciously. A few cut prices are reported, but they do not affect trade much, quotations remaining at $4.65 for thin-vein Allegheny Valley, all sizes; $4.45 for Pittsburgh and No. 8 lump; $4.20 for same, mine-run and slack; $5.60 for smithing and smokeless; $5.60 to $6.10 for cannel; all per net ton, f. o. b. Buffalo.

Anthracite—The coal is accumulating here quite rapidly. Some companies are managing to hold it somewhere else, others are either seeing it stand in cars or are putting it into stock piles. In any case the outlook is not pleasing. The spring is coming on, when the consumption is sure to be small, and then a long summer with little buying; for the consumer is not frightened any longer and still hopes to see prices return to former figures, though it does not look as though he would see lower prices right away.

Some shippers are saying that the logical thing is to put a lot of this coal afloat here, but nothing is done about it. A while ago there was tonnage asked for, but it was not taken and the prospect of any being loaded right away is not good. Shippers appear to be afraid that it will be moved west before any is needed there and the yards there be loaded full of it. The situation is one that could not have been thought possible till quite lately, for it has come to be the belief generally that anthracite would never be plentiful again.

CLEVELAND

Decidedly more snap is being shown by both the steam coal and domestic markets. For the former, depletion of stockpiles is given credit; for the latter, cold weather. The outstanding development is the report that at their meeting at Indianapolis, Mar. 18, the United Mine Workers will propose that the present wage scale be continued for two years.

Bituminous.—Not in months have local operators been stirred by anything as by the report that the United Mine Workers, when they meet at Indianapolis Mar. 18, will propose that the wage scale now in effect be continued for two years. In addition to furnishing a choice morsel for discussion, it has helped stiffen the market and prompted more predictions that No. 8 coal prices will continue at or close to their present level for some time. Operators are by no means unanimous in their views. Some believe that so long as commodity prices remain high, it will be the part of policy to keep wages up. These operators hold to the view that the public foots the bill, in any event, and that greater efficiency and harmony can be attained by maintaining the scale. Other operators are flatly against the present scale, and are insistent that it must be reduced.

Although operations at the mines have not been accelerated, the market, especially for steam coal, is broadening. In some instances the bottoms of stock piles are beginning to show. In other cases, users with fair-sized stocks still on hand are beginning to buy. A great deal of buying that was delayed because of a belief lower prices were inevitable is beginning to be revived. Many operators profess to believe the tide has turned and that the market will consistently become brighter. Hopes for an export outlet for coal all have faded, and this causes considerable disappointment.

The combination of real winter weather and a plentiful supply of much-sought Pocahontas has stimulated domestic demand for bituminous to the highest point of the winter so far. All hopes of doing a winter business have been abandoned, however, and any improvement is only relative. Dealers are getting $7.50 for Pocahontas lump and $7.20 for run-of-mine, and report a fair business at these prices. Retail dealers continue to receive numerous offers of second grade and off coal, but the coming of Pocahontas and the still ample supply of anthracite have pushed bituminous out of the running.

Anthracite—Receipts continue equal to demand, but are lower than a week ago. Pocahontas users are leaving substitute anthracite in the lurch, now that their favorite is obtainable. The delivered quotation continues $10.85.

Lake Trade—Loading machines at Lake Erie docks are being overhauled preparatory to the beginning of the season. Early cargoes are not being sought with much vigor, for dock piles at the head of the lake still are the largest in years—for this period of the year. In the absence of a new price last season's will hold over. The entire lake situation hinges upon the decision of the United States Railroad Administration on the request of lake shippers that demurrage rules be modified in order to permit abandonment of the pool and resumption of private shipping.

DETROIT

Because of the large stocks of bituminous remaining in retail dealers' yards and at many manufacturing plants, the Detroit market is inactive.

Bituminous—Withholding of orders by consumers of steam coal and retail dealers is still accompanied by the explanation they already have more stock on hand than they feel is justifiable, according to Detroit jobbers, who find business is unusually light for this period of the year. Large users of steam coal, who usually have been arranging contracts at this time in previous years, either have stocks sufficient to meet their requirements for some weeks to come or have decided the present is an inopportune time to take on new commitments.

Jobbers find some of the industrial consumers are buying only for current pressing needs and seem to be looking for a reduction in coal prices about April 1. Efforts to convince these customers that they are likely to be disappointed are not altogether successful, though the jobbers argue that with the present high wages of miners and unusual additions to operating costs, the producers are more likely to advance than to lower the price now in effect.

On most of the business that is being done the jobbers say the fuel administration scale of prices is being observed. Some exceptions have been reported, however, where coal on tracks was accumulating demurrage or was not of a type sought by buyers.

Retail dealers are expecting an improvement in demand from domestic buyers to follow the drop in temperature that marks the passing of February. So short a time remains before warm weather may be expected to return that the belated buying is unlikely to relieve the retailers of the necessity of carrying burdensome stocks of bituminous over into the summer.

Anthracite—With all restrictions on use of anthracite for domestic purposes now removed, the larger proportion of inquiry from householders is for anthracite or coke. Dealers appear able to supply either in reasonable amount, although receipts of anthracite are still of small volume. Intimations are given that an increase in price of prepared sizes of anthracite, amounting to 50 to 75c. a ton, may be expected in the near future and that the reduced price usually in effect after Apr. 1 to facilitate early distribution is unlikely to materialize this year.

COLUMBUS

The coal trade has been rather quiet during the past week. A short cold spell stimulated domestic buying, but it was short-lived and the weather is again exceedingly warm. Steam buying is not active, although inquiries are more numerous.

The coal trade in Ohio has continued quiet in all regards. The expected cold wave predicted by the weather bureau arrived, but the temperature was not a great deal lower and it was soon followed by the unseasonable weather that has prevailed all winter. Consequently, the domestic trade is still quiet and continues to be a weather proposition pure and simple. Retail stocks are large and there is no disposition to increase them under present conditions. There is still some demand for Pocahontas and other fancy grades, but the tonnage moving in this territory is not large. Retail prices are still generally maintained, although some cases of price cutting are reported. Household stocks are still large and many consumers will carry over a considerable tonnage until next year.

Steam trade is quiet in most localities. Traveling salesmen and jobbers report a better disposition on the part of purchasing agents to talk fuel, which is taken as a good indication. In other words, one can get the attention of purchasing agents to discuss the fuel proposition where it was almost impossible to get them to do so several months ago. Iron and steel plants are still well stocked and the same is true of rubber factories. Some of the manufacturing plants are slowly getting on a peace basis and are in the market for fuel. But orders are still scarce and are hard to land. Quite a few contracts expire around April 1 and there is some speculation as to what the new contract price will be. All the old steam contracts in this territory carry the Government figures. Some predict that shading will take place, while others believe the price will be maintained generally.

Production is still slow, as is inevitable under present conditions. Some railroad fuel is being mined, but railroads are not using as much as formerly. Steam plants, especially public service concerns, are taking a fair tonnage. It is estimated that the output in the Hocking Valley is about 25 to 30 per cent. and the same figures are reported from Cambridge and Crooksville fields. Pomeroy Bend is credited with 35 per cent. output. The eastern Ohio field is curtailed to about 30 per cent. production.

CINCINNATI

Mild and rainy weather has again reduced consumption. Production is being decreased to meet the situation, pending completion of marketing plans.

The coal trade as a whole is in the throes of readjustment to peace conditions, and to an extraordinary winter, which, after occasional hints of some real wintry weather, always turns again to mildness. This makes the need and the demand for coal very small as compared with the available supply. During the past week mild and rainy weather has prevailed, and consumers of all classes, seeing their stocks still adequate, and with prospects of an early spring, have naturally refrained from further buying. Deliveries of coal on contracts, therefore, have more than taken care of the needs of industrial consumers, as heretofore.

It is fully apparent to the trade, aside from the conditions brought about by heavy storage of coal last summer and a mild winter, that the process of getting back to a basis of normal consumption is still to be worked out, and that the present situation is playing its part in that work. In other words, it is pointed out by clear-sighted coal men that operations brought into activity purely by war business are suffering most by the present lack of demand, and that eventually mines which are without economic justification under normal conditions will have to be eliminated, as far as the ordinary run of business is concerned. This process, it is admitted, is painful, but it is also admitted that it is necessary, unless there are some means found of maintaining the country's industrial machine at the high mark of activity forced by the war, which it hardly considered possible, or at least, probable, just now.

LOUISVILLE

Steam continues inactive, with domestic in fair demand only. Prospects for steam slightly better. Coal operators believe that summer stocking will be light unless steam improves.

There has been no material change in the general situation in the Kentucky fields during the month. Mar. 1 finds the situation about the same as on Feb. 1. Steam coal is draggy, and some operators have been forced to ship steam without orders so as to get it out of the way in order to produce domestic, for which there is a fair demand.

Retail demand shows some slight improvement due to a few cold snaps and the fact that many consumers are beginning to run low on winter stocks, resulting in a fair demand for small lots.

It is believed that steam coal will be in much better demand by Apr. 1, due to the fact that many stocks are beginning to peter out, that some industries, especially the automobile industry, are again busy. Gas plants, public utilities, etc., are taking a fair quantity of coal.

Many operators are of the opinion that even if domestic consumers desire to stock during the coming summer period the retailers will have trouble in securing domestic sizes, unless they stock resulting steam grades. Many operators are now making their domestic sell their steam where possible.

The demand for low grade coals is light, and many of the eastern Kentucky producers of poor grades are at a standstill. The wagon mines are generally down. The larger mines are operating two to thsee days, whereas a few minei with good contracts are managing to keep busy almost full time. Production for the state, however, is figured at about 45 to 50 per cent. normal. Western Kentucky is producing on about the same schedule, but is having trouble in keeping up a demand for low grades.

Prices are holding fairly well, although about 25 per cent. of the operators are cutting somewhat in order to secure business. Domestic is firm, and on new business operators are holding for premiums of 15 to 25c. a ton, but generally supply old customers at Government prices. All grades under 4-in. are hard to sell, and are carrying a cut of from 20 to 75c. in some cases. Straight mine-run is about 25c. a ton off. Screenings represent the hardest problem at this time.

Retailers are generally carrying short stocks, and buying as needed, not carrying more than a few cars of coal on hand at the most, as deliveries can be had on short notice. It is now believed that a good deal of river coal will come in during the summer stocking season, and already a little coal is coming down, while it is reported that a good deal of coal is being loaded at upper Ohio River points.

Coke

CONNELLSVILLE

Less demurrage coke but regular make offered at lower figures. March adjustments in progress.

The furnace coke market is distinctly steadier in the respect that there is now little demurrage coke being offered at any price it will bring, but on the other hand some operators are willing to accept lower prices on regular orders. Thus while there is hardly any coke to be picked up at extremely low prices it is possible to buy coke, still to be made, at lower prices than formerly. Several leading operators are holding $5 strictly as minimum for furnace coke, but a few at least would sell down to $4.50, either a small lot or a run of a fortnight or a month. Regular brands of foundry coke are held fairly well at $6, but there is some shading of this figure. The spot and prompt market is quotable at $4.50@5 for furnace and at $5.50@6 for foundry, per net ton at ovens.

Negotiations are in progress to settle prices at which coke is to be invoiced during March under contracts calling for a negotiation when there is no Government price to control. It is not improbable that these adjustments will be made in most cases at $4.50, though some operators are trying to obtain more. In some instances the operator owes the buyer something

through the adjusted price for February having proved too high to be representative of the market. In some instances this fact was recognized by an extra adjustment in February. A case is cited, for instance, in which the parties agreed upon $5.50 for February, but the market soon proved so much lower that the operator made a concession covering shipments during the second half of the month such that the average for the whole month was made $4.75. Another illustration of market conditions is that one interest which controls both coke works and blast furnaces is billing the coke at $4.50, regarding that figure as fairly representative of the market.

The "Courier" reports production in the Connellsville and Lower Connellsville regions in the week ended Feb. 22 at 233,612 tons, an increase of 33,256 tons. The merchant oven production of 82,490 tons, however, showed a decrease of 3646 tons.

Buffalo—The situation does not look so bright as it did, for the amount of iron ore on the docks is heavier than for a long time and it is going to affect the summer movement of it seriously. The furnaces are not running strong and the demand for coke is less and less. Prices are weak. This market reports that what is needed can be had at about a dollar less than the former Government prices, and that anything of less value than 72-hour foundry is selling at terribly low prices, so low that quotations are hardly possible. Fuel coke is as dull as bituminous coal and will have to continue along with it.

Middle Western

GENERAL REVIEW

Labor difficulties at the mines would lead to coal scarcity. Steam market is dull. No contracting in evidence. Brisk demand for domestic coal.

Coal men are wondering what effect the tremendous decrease in the production of coal will have on the country. The rapid falling off in production since Jan. 1 is worthy of a lot of thought, especially on the part of the purchasing agents who buy large quantities of coal. If production is kept at its present low level, soon there will be a shortage of coal, even taking into consideration the fact that there are still some big storage piles throughout the country. Should any serious labor difficulties arise around Apr. 1, and such a situation is not at all improbable, it would find some of our most important industries practically without coal. In times as unsettled as the present the wise purchasing agent will have at least one to two months' supply of coal on hand.

The steam market is dull, if possible even as dull as last week. The bids made for the Camp Grant business have all been refused, and it is understood that Camp Grant will buy on the open market, for the time being. The big buyers are purchasing a little coal, but not enough to have much effect on current conditions.

Usually at this time of the year the coal man is exerting all his energies toward getting contracts, but this year to date but few new contracts have been made. Those agreements that have been made were entered into on a basis of Government price last in effect. The coal operator is not over-anxious to contract at the present low figures, because he believes that better times are coming. The purchasing agent is not very eager to contract because he thinks that within a short time the market will be demoralized, and operators will jump at any business on any terms. Personally, the writer believes that from the standpoint of the buyer, now is the time to contract.

The railroad fuel situation at this writing does not appear to be any nearer a solution than it was six or eight weeks ago, and criticisms of those to blame for this condition are becoming louder and more pointed from day to day. Coal operators think that somewhere they may have friends, but at all events they are not in Washington.

There has been, considering the past, a brisk demand for domestic coal throughout the Middle West. Most dealers had but limited stocking space, and it appears that what storage of domestic fuel there was in the territory has been absorbed.

Prices continue firm, both on steam and domestic. The operators are showing the public they have no wish to return to the old days of selling their product a little cheaper than their competitors.

CHICAGO

Colder weather stimulates steam and domestic demand. Not as much Eastern coal coming in as was expected. Anthracite moves slowly.

Chicago is enjoying a cold snap; that is, the coal producers are enjoying it. The result of the near zero weather we have been having for the last few days is a decided quickening of the trade, both steam and domestic. During an ordinary winter, times like the present would be considered very dull, but under existing conditions, the coal trade is very grateful.

Some Eastern coal is coming into Chicago and its suburbs, but not merely so much as was expected. The retail trade apparently like Mid-Western coal, and are refusing to go back to the more expensive coals from West Virginia, Ohio, etc. Anthracite continues to move slowly, although sales agencies are combing the territory for orders.

MILWAUKEE

Price-cutting by Illinois operators causes a nervous feeling among holders of large stocks of soft coal. Efforts being made to ward off a general decline in bituminous. A weather market.

Shading in prices by several Illinois operators is causing uneasiness in the Milwaukee market, and holders of bituminous coal are conferring with each other and doing what they can to avert a general decline in the soft-coal schedule. With spring at hand, and operators well stocked, there is no telling when this will occur. The situation is unquestionably dubious.

Retail prices on all grades of coal and coke have been firmly maintained thus far.

Bituminous stocks are heavy for the season, but the anthracite which was received by lake is nearly gone. This grade of coal is coming in freely by rail, however, and there is no trouble in supplying the demand. There are more users of soft coal in Milwaukee than ever before, and should anthracite continue at anything like present prices next season there is no doubt that many will continue to use the soft varieties.

Coal is moving out more freely from the yards, both by wagon and rail, because of a spell of cold weather; but the season is too far advanced to expect zero weather to remain very long.

It is certain that there will be a large amount of soft coal on the docks when the lake shipping season opens.

ST. LOUIS

Heavy market continues on all sizes from all fields with practically no demand for anything. Weather trifle colder than it has been, but nothing to warrant any decided changes in local conditions.

A heavy market with no changes of any kind is the local situation. The latter part of the week there was colder weather, but this was not enough to cause any unusual demand for coal, either steam or domestic. There were some small orders for domestic use and the wagon-load steam business responded slightly, but other than that there was no improvement.

Country business picked up a little on domestic sizes on the strength of a cold wave, but it was not anything to bring about any change in prices or create any shortage.

In the Standard district there still continues to be a surplus of steam sizes and at some mines a surplus of domestic sizes, with mines working one or two days a week. Occasionally some of them get three days.

The railroad tonnage is extremely light, but it is a factor at this time in keeping some of the mines going that would otherwise be idle.

The Mt. Olive field, which is putting in practically no coal in the St. Louis market, is doing exceptionally well on outside business in the northwest and Chicago.

It is understood that one of the last acts of the local fuel committee will be a letter eliminating the classifications made in the early part of the Fuel Administration pertaining to Illinois coals in the St. Louis market. This will help the Mt. Olive district considerably.

The present prices, which are below the cost of production, cannot continue for any great length of time without causing final disaster to some of the operators.

In the Carterville field of Williamson and Franklin Counties, as well as in the Duquoin field, there is a scarcity of orders for both steam and domestic sizes. All of the operating companies have the territory combed pretty closely now with the salesmen, but that does not seem to get the business in sufficient volume.

The Government prices in these fields are being maintained, excepting in Williamson County, where the independent operators are selling at $2.55 and below for domestic sizes. In the Mt. Olive field the Government price is being maintained, while the Standard field shows a continued weakness.

The local anthracite situation is not very encouraging. There is some chestnut, stove and egg moving in, but this is nearly all going into storage. The domestic demand is light.

Statistics furnished by the Tidewater Coal Exchange show that the situation has greatly improved, and on its recommendation all embargoes on coal consigned to all piers in the New York harbor have been removed.

The prevailing market, with the exceptions as noted above, is as follows:

Franklin County		Mt. Olive and Staunton	Standard
Prepared sizes, lump, egg, Nos. 1 and 2 nut	$2.75	.....	.....
Williamson County			
Prepared sizes, lump, egg, nut	$2.55	$2.55	$1.75 up
Mine run	2.20	2.20	1.65@1.75
Screenings	2.05	2.05	1.00

Williamson-Franklin rate to St. Louis is $1.10; other rates 92½c.

COAL AGE

Volume 15 New York, March 13, 1919 Number 11

Humanizing Industry

By Floyd W. Parsons

TWO kinds of people are a menace to America. They are both extremists. One has too much imagination; the other too little. Both are selfish, unreasonable and autocratic. Both work from different ends toward the same unhappy center. There would be no violent radicals if there were no ultra-conservatives. One is the fruit of the other's planting.

In every industry throughout the United States are men who refuse to advance with the times. They hold steadfast to ideas of the 1890 blend. In their outlook on business they do not recognize any need to study human reactions, although they would not think of building a machine without first getting a satisfactory report on the properties of the materials entering into it from the company's research laboratory.

Industrial troubles in recent years have come largely from an effort on the part of many employers to make workmen act as nearly like machines as possible. A new mine is opened or a factory started, and men are poured in very much the same as metal is poured into a mold. If labor is plentiful, the men pour easily. However, one thing is overlooked, and that is the fact that there is a decided difference between getting a real working force and filling a mine with men.

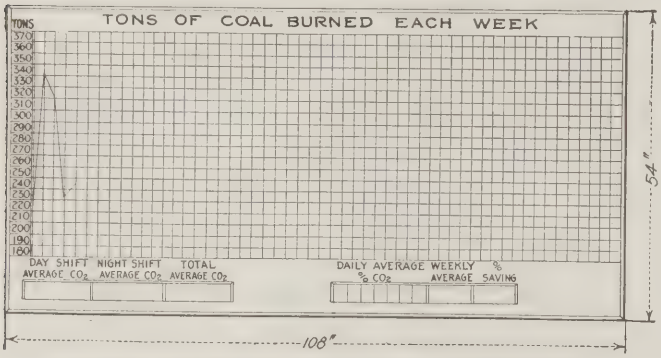
The employer cries aloud against his large labor turnover. When asked the reason, he attributes it to human perversity. He does not investigate carefully, or he would soon discover that job changing is unnatural; the normal man wants to settle down and have a permanent home and a steady position. One truth is now recognized, that the worth of a management can be determined by the size of the labor turnover.

It is interesting to know why a workman will loaf consistently each day and then work diligently on some task at home after hours. Let the manager ask himself, "Is this the fault of the man or the job?" When a man is more interested in doing something outside than he is in attending to the job for which he is paid, it is a sure sign that the employer has withheld from him all measure of personal responsibility. He has been permitted to work in monotonous fashion without any understanding of his real value in the final outcome of things.

No workman can be efficient unless he knows that his accomplishments will reflect credit or discredit upon him, according to the skill he exercises. He must be permitted to satisfy his creative instincts. He must be taught that the most perfect machine is only a tool; that he is its master and can make it effective or not, just as his skill directs. Not until the workman feels the sense of mastery will he assume responsibility. Idle machine hours and high costs exist where men and machines are equal.

It is all very well to talk of supervision from above, but there is greater efficiency when supervision springs from below. The man who is truly creative does best unde a policy of self-supervision. Stop a minute and investigate the cause of success of certain managements. It will be found that this success is based on a policy of satisfying the natural instincts of employees.

The primary instinct of a man is to preserve his family. This means he must receive a minimum wage that will afford a certain degree of comfort and pleasure besides a mere sustenance. No man can think of his work with pleasure if it provides him with a bare living. And right here it is important to note that a living wage is not measured by the amount a workman receives in any one week, but by the income he receives for his year's labor. As a natural sequence it follows that where consumption has not been curtailed by high prices, the more idle days that occur in an industry the higher the wages must be fixed to afford the workmen in that industry a decent living. A bear can go into his cave and live on nothing for several months, but not so a human being.



The coal industry is confronted by a serious problem. Plans must be perfected to make the production of coal something more than a seasonal affair. Capital and labor cannot go forward in harmony unless first there is regular employment for the men at a minimum wage. It is useless to discuss ways leading to efficiency and cooperation in and about the mine unless there is a base wage for the miner that will fully cover his cost of living through the full year. After this is a fact we can go on and talk of better results through self-government, and of quality and quantity production through a superior kind of industrial democracy.

IDEAS AND SUGGESTIONS

Coal-Curve Board for Use at Power Plant or Mine Mouth

BY H. H. FINCH
Springfield, Mo.

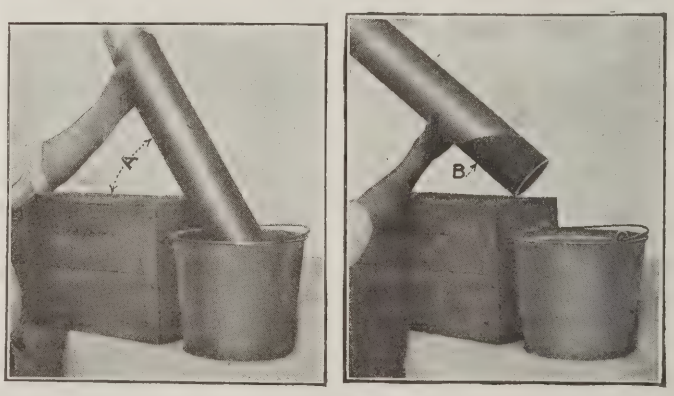
The accompanying drawing shows a coal-curve board that may be used either at the power plant or the mine mouth. This board is 108 in. long and 54 in. high. It is made of good grade of flooring, scraped smooth and painted black with white lines. There are 52 spaces provided, each space representing one week. This gives a year's curve, which may be painted with white paint one year and another color the next. The board will

BOARD PROVED OF VALUE IN POWER PLANT

thus afford space for curves for three or four years, so that results can be readily compared. Such curves are extremely interesting and should be placed in or near the boiler room. The CO_2, which may be marked up daily for the day and night shifts, is also an interesting feature.

This scheme has been used at the plant of which I have charge since Jan. 1, 1919, and we have found it a fuel saver. The daily CO_2 percentage is marked in chalk and each fireman can see his work; and not only he himself but others can see his percentage. I made a drawing of this board and had it built and painted at the plant. The squares are of 2-in. dimensions.

A board of similar design might well be used at the mine entrance to show the weekly output of the operation. In such a case a second curve might well be drawn showing the number of total employees or miners. The average output per miner or per employee might be drawn as a third curve.



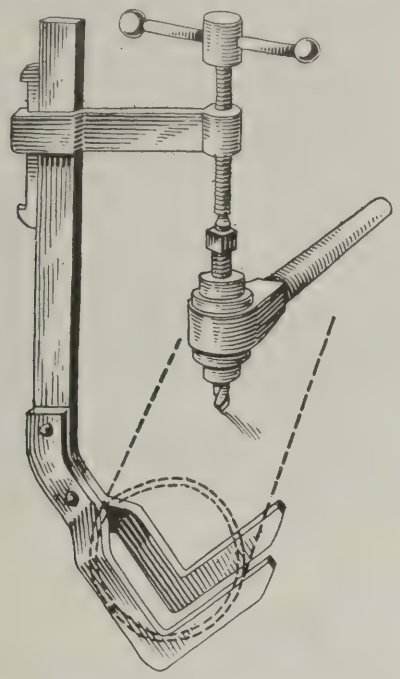
Novel Method of Moving Cars Back and Forth on a Switch

It frequently happens that one industry may with advantage borrow or adopt an idea or device from another with which it has no direct relation or point of contact. The following scheme for moving empty or partly loaded cars might well find application at many mines. In a mill where it is necessary to unload grain from railroad cars at several points, and to load the finished product at different places along the warehouse platform, there is a problem of moving the cars back and forth on the switch. The empty cars can be moved by manpower, but a car that is partly loaded requires a switch engine, which is not always available.

The Pasco Flour Mills Co., of Pasco., Wash., a new mill that has installed electric drive throughout, is utilizing its drive in an ingenious manner to solve the problem of car switching. The mainshaft in the mill is driven by a Westinghouse 40-hp., three-phase motor. A countershaft, driven from the mainshaft, projects through an aperture in the wall of the mill to the loading platform. Attached to the end of the countershaft is a steel spool, or niggerhead, on which a coil of 1¼-in. rope may be wound. The loose end of this rope is attached to the coupling of the car to be moved, by means of a steel hook. By throwing the countershaft in gear the drum revolves and moves the car. The direction of the pull from the drum is made by changing the winding and lead of the rope on the spool. The device is homemade.

Inexpensive Liquid Miter Makes Easy the Cutting of Angles

It is often desirable to cut or saw metal or wood at a special angle. Such an operation would necessitate the use of an expensive adjustable miter, the price of which is often too high for the work in hand. To overcome this difficulty at the least expense a liquid miter



METHOD OF USING LIQUID MITER

may be substituted for use on wood and polished or dull metal. For polished metal, a few crystals of sulphate of copper are dissolved in a suitable container; the end of the piece to be sawed is placed for a few seconds in this liquid, in such a position as to form the desired angle to the horizontal shown at *A*. When allowed to dry, the copper solution will oxidize the piece, as shown at *B* and leave a definite guide line for cutting. For rough metals or wood a solution of lime may be used, thus leaving a clean, white line as a guide for the correct cutting of the angle.

Homemade "Old Man" for Drilling Pipe

The device shown in the accompanying illustration is homemade, and is used for drilling pipe. These are placed on the saddle, which consists of two iron straps, bent and riveted to form a fork-shaped end piece. The

SIMPLE DEVICE AIDS IN DRILLING PIPES

adjustment for the height of the arm on the main bar is made with a wedge, which bears against the bar. The feeding of the ratchet drill is done by means of the feedscrew shown. This device is comparatively light, weighing ordinarily only about 4½ lb., and is therefore easy to handle.

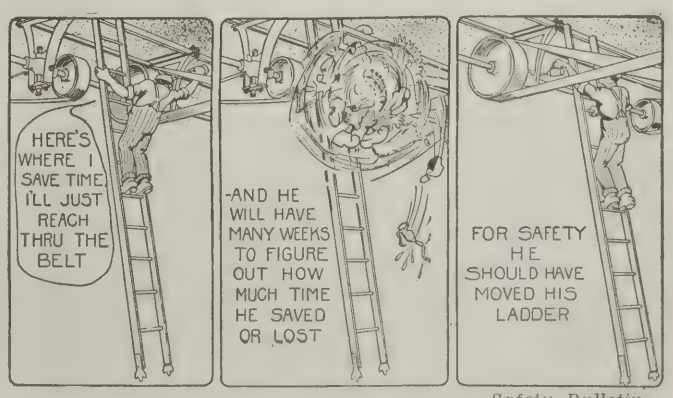
Efficient Locomotive Haulage Depends a Great Deal on Motorman

By E. Steck
Hillsboro, Illinois

There has been considerable discussion in the past regarding the proper size of locomotive and motor equipment required to haul a trip of cars where the number of cars, weight of car and capacity have been given, as well as the grade conditions and the distance of the partings from the bottom. Theoretically, this is a simple calculation; but practically it must be considered from many angles. The theoretical formulæ have often been stated, but just as much consideration should be given to the practical end. The following must be taken into consideration: Motorman, sequence of grades, condition of rails, delivery of cars to partings, capacity of bottom, bonding, trolley and feeders.

The motorman can greatly overload a locomotive that is theoretically the correct size by stopping on or at the bottom of grades against the loads, making it necessary to cut the trip in two; whereas a good motorman would take the grades with sufficient speed to enable the momentum to help carry him over. The poor motorman will use excessive sand on grades to keep the wheels from slipping, but at the same time greatly increasing the electrical resistance between the wheels and rails and thereby reducing the hauling capacity. Such a man pays no attention to the number of cars per trip, sometimes coming to the bottom with a very small one and then again with a trip much too large. Either too small or too large a trip will cut down the tonnage capacity of the locomotive.



If haulageways are rolling, the grades with the loads can be utilized to some extent to obtain enough momentum to help pull over the grades against the loads. If all the grades are against the loads, a larger locomotive will be required for the same per cent. grades than in the first case. Right here is an opportune time to state that a locomotive operating over an entry which has a short steep grade against the load will not require as large motors as one operating over a perfectly level road.

Where a short steep grade occurs, the size of the trip is limited by the slippage of the wheels on the grade. This trip is obviously much smaller than the one that would be required to slip the wheels on the level road. In the first case the locomotive is only fully loaded on the hill, and while running over the level part of the road it is underloaded; in the second case the motor is fully loaded all the way. As the capacity of the motor is limited by its heating, which in turn depends on the amount of current and the time during which this flows, it is readily seen that the locomotive fully loaded on level track has the hardest work to perform.

A locomotive will pull more over a dry, clean rail than a wet, sandy or dirty rail. If the working conditions are such that the partings from which a locomotive pulls cannot be kept full enough to make a proper trip, the locomotive will be underloaded or, in other words, too large. If on the other hand the parting holds too many cars, the motorman is tempted to pull them all, overloading the locomotive. In either case the locomotive will not deliver the maximum amount of coal possible.

If the bottom is small, or if the hoist is slow, a large locomotive is not practical, as the bottom will become blocked. In such a case a small locomotive could be used to better advantage.

He Tried to "Save" Time

FIG. 1. GENERAL VIEW OF NO. 87 PLANT AND TOWN OF IDA MAY

Modern Shaft Development of the Consolidation Coal Company—I

By George W. Harris
Editorial Staff, *Coal Age*

THE old wooden frigate with all sails set looked every inch a sailor—years ago. It loomed up much more imposing at a distance than the modern dreadnaught, deep set and with its decks almost awash. What a transformation time has wrought! The new type includes every mechanical device adapted to the many services required in operating the modern craft. Manual labor has been done away with wherever practicable. Turning from the sea to firmer footing, we have similar examples of time's changes. In the coal fields the old wooden tipples have not usually been scrapped, but were allowed to serve out their term of usefulness. However, when these old structures are to be replaced or when virgin territory is to be developed, the improvements partake more of the modern steel fireproof construction.

A new plant is the joy of all concerned. Here is an opportunity to cut loose from old methods. No patching up of old buildings and fitting in of new machinery on old structures here. The modern shaft development of the Consolidation Coal Co. at the head of Helen's Run, in northern West Virginia, is a typical case of this kind. The improvements started in this section reflect the value of the coal underlying this territory—it is one of the fine deposits of the Pittsburgh seam and worthy of the best efforts of manager and engineer in its extraction. Some 6500 acres of coal are included in this tract, which is to be attacked at two points about two miles apart; provision has also been made so that additional acreage can be mined at these plants if desired.

Mines No. 86 and No. 87, here referred to, are about seven miles due west from Fairmont. Their location is shown on the map of the Fairmont coal field on page 1150 of the Dec. 26, 1918, issue of *Coal Age*. They are practically in duplicate as far as layout of plant and tipple design are concerned, accordingly one only—mine No. 87—will be described and illustrated. This duplication of plant is also found in other coal fields in a limited number of cases. It is entirely in keeping with modern practice in this respect, as witness the history of the Liberty motor of recent fame. When a number of units are to be built which can be practically identical in design, then it would seem to be the part of wisdom to perfect this unit as far as possible and utilize it as a model.

A general view of mine No. 87 and the town of Ida May is given in Fig. 1, the store and surface plant being shown toward the left in the illustration. The surface plant at the mine is shown more in detail in Fig. 2; beginning at the left, and in the order named, are the tipple with the hoist house adjoining, the airshaft headframe and the shop. Mine No. 87 was started in April, 1915, and since that time a full-fledged operation has sprung into existence, only requiring another year's extension of underground work to bring the plant up to full capacity—3000 tons of coal in eight hours. This tipple is shown in perspective in Figs. 3 and 4, and the machinery and chutes are shown in section and plan in Fig. 5.

Coal-preparation buildings—both anthracite and bituminous—have seen many changes in the last 25 years. The modern breaker or the tipple is no longer a dark, barn-like structure. Especially since the free use of structural steel in their construction has great improve-

ment been noticed in the design of the buildings. Greater attention has been paid to the more efficient use of space and the better lighting of rooms where this feature is important. A gradual reduction in the height of breakers and tipples has been the tendency wherever practicable; this was brought about first by the use of elevators and further by the adoption of traveling tables and shaking screens, which replaced chutes and bar screens in part. The traveling tables, with their added refinements, designed to lessen breakage of coal, especially conserve lump and other sizes of bituminous. The dropping of coal is more and more eliminated, the loading boom taking coal from the tables places lumps in the railroad car in good condition; this is the last step in the greatly improved method of handling coal in tipples. If a concrete example was desired to illustrate the last word in bituminous tipples, possibly no better plant could be considered than the Ida May structure shown in the accompanying illustrations. In this tipple the dump hopper and first, or upper, shaking screen only are in the highest part of the tipple proper and the rest of the preparation machinery is in the low shed over the loading tracks. The lighting and ventilation of the interior of this building are largely accomplished by movable skylights—a common practice in modern shops but somewhat of an innovation in tipples. The floors and walks of the tipple are of concrete.

The No. 87 tipple is a strikingly low structure, being only about 43 ft. in height from the surface to the dump. Coal from the shaft is dumped into the receiving hopper, from which it is carried to the shaking screens by means of a heavy pan conveyor feeder. The screens are 8 ft. wide and are designed to handle at least 4000 tons per day. They are operated by the Allen & Garcia center crank drive and are carried on Peterson pendulum hangers, handled by the Allen & Garcia Co., of Chicago, Ill. The upper screen has two screening decks, the upper making lump over 1½-in. lip screens, the lower deck rescreening the 1½-in. slack over ¾-in. lip screens. Either 1½- in. or ¾-in. slack can be loaded on the second track and 1½ x ¾-in. nut coal can be loaded on the third track through a telescoping hinged chute. If the gates are closed, the nut coal or the nut and slack as well as the lump are carried to the lower section of the screen. The upper deck of the lower screen contains one section of 4 x 6-in. oval perforations, which are covered by a bolted veil plate when not in use. Below this point there is an interesting and novel feature consisting of two large vertically lifting gates each half the width of the screen; they are provided with sides and deflectors so arranged that the coal is divided equally between them. These gates are operated by means of handwheels and sliding nuts, so that they can be manipulated without stopping the screen and be held in any position without additional locking.

Thus a great variety of operations are possible: Run-of-mine, 1½-in. lump or ¾-in. lump can be divided between two 5-ft. picking tables and be loaded on the fourth and fifth loading tracks. The entire product can be thrown to either table. Or egg, egg and nut, or egg, nut and slack can be loaded on the fourth track with the resulting lump on the fifth track. In every one of these operations the coal slides easily to the discharge point, and there is no serious drop and breakage anywhere. The whole outfit was designed to handle lump coal especially, with the minimum amount of breakage, and it is questionable if there is another plant capable of making a better record in this respect. As an additional precaution each size of coal goes over a degradation screen just before reaching its loading chute or table, and the product of these screens is carried back into the slack car by means of a degradation conveyor.

When the lump or egg coal leaves the lower shaking screen it will pass over two picking tables and loading booms, where an opportunity is given for the removal of refuse. Only one of these tables has been installed up to date. Men stationed along these tables pick out impurities and throw them into the primary gob conveyor alongside. The primary line delivers to the main gob conveyor running along the outside wall of the tipple and emptying into a rock bin adjacent to the hoist shaft. This main conveyor and rock bin are shown

FIG. 2. VIEW OF THE SURFACE PLANT AT CONSOLIDATION COAL CO.'S NO. 87 MINE

on the plan and section, Fig. 5, and along the outside of the tipple, Fig. 4. When rock is hoisted in the shaft it is dumped into the receiving hopper, but is prevented from following the usual course of the coal by deflecting gates controlled by the lever *C*. Thus rock goes by chute to the rock bin.

When run-of-mine is to be loaded it can either go direct by way of the auxiliary mine-run chute into a car on the first track or be deflected by a gate (opened by the handwheel *A*) from the upper shaking screen into the principal run-of-mine chute. This chute loads by means of telescoping and hinged apparatus either into a car on the first or on the second track, the loading being controlled by a hinged vane. This system of run-of-mine chutes was designed to handle occasional runs of coal which might contain impurities—such coal being thrown to a car on the first track. The gates controlling these chutes are all operated from the dump-house platform, where the coal is inspected as it comes up in the conveyor feeder. The chutes leading to the first track have not been installed yet, but all arrangements have been made to have them placed in position eventually.

At present mainly run-of-mine is loaded at this plant. At times there is interruption to car delivery at the loading chutes and provision was made for such contingencies by providing a controller for the motor operating the feeder at the receiving hopper. This controller is located on the main floor of the tipple over the loading tracks. Outside foreman C. H. Shear devised a scheme whereby this controller is operated by the car trimmer standing on the platform while loading run-of-mine. Wires run from this point, over pulleys at turns, to a handwheel on a vertical shaft at the controller. This arrangement takes the place of the usual hand lever and does away with the necessity of keeping a man at the controller. A car retarder, made by the Fairmont Mining Machinery Co., of Fairmont, W. Va., is installed at each loading track.

Another quite interesting feature of this tipple (the idea originating with the designers) is the concreting of three sides of the hoist shaft from the surface to the dump. The steel members of this portion of the tipple frame are light and the concrete encasement was designed not only to give greatest strength and rigidity to the structure, but to keep coal and dirt from dropping inside the screening portion of the tipple. The concrete also protects the steel members from the corrosive action of the mine gases coming up the shaft. The designers of this tipple claim that they have met with great success with this style of construction and that they are using it on several of their newer tipples.

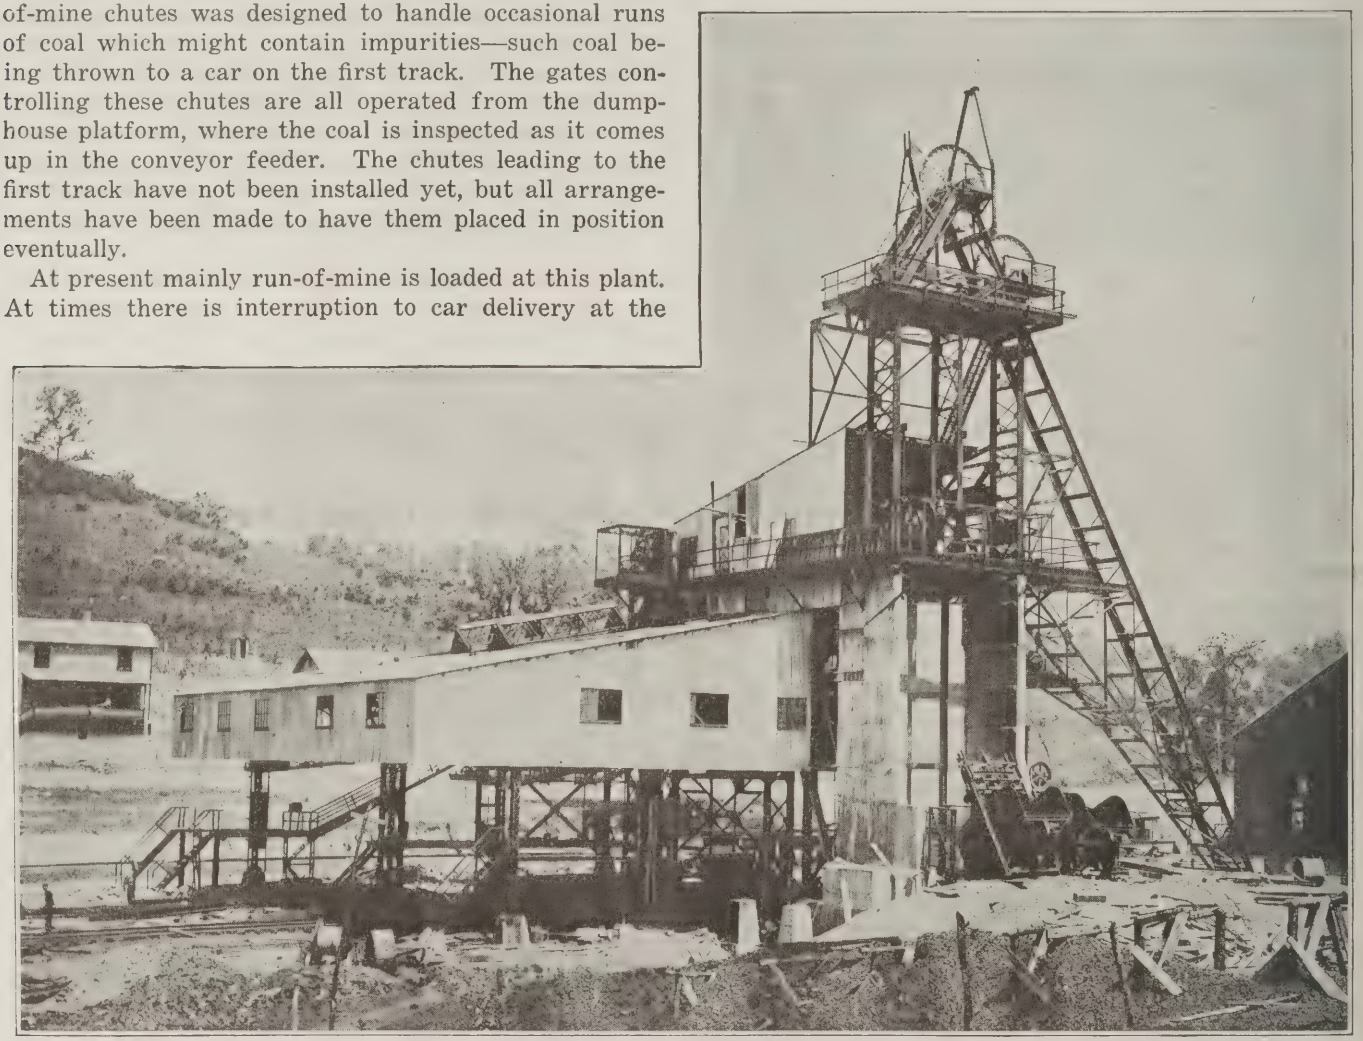

FIG. 3. LOOKING AT THE TIPPLE AT THE NO. 87 MINE FROM THE LOWER SIDE

Modern tipples and towers or headframes are generally equipped with some provision for instant and efficient handling of sheaves; in the No. 87 tipple a derrick combination is provided for this purpose. The derrick details are brought out in Figs. 3 and 4. A different method for handling sheaves is provided at the top of the airshaft headframe as shown in Fig. 2. This is the common method in use for the ordinary placing of sheaves.

Adjacent to the tipple is the house containing the electrically operated shaft hoist, fully described in the July 13, 1918, issue of *Coal Age* under the title of "Motor-Driven Shaft-Hoist Installation," by R. P. Hines. This hoist has a cylindro-conical drum operated

by a General Electric 1400-hp. motor on the Ward Leonard system of control, combined with the Ilgner flywheel method. This flywheel has sufficient energy, in case of the failure of current from the main supply line, to hoist and land a cage; thus it should not be necessary to stop the hoist at any point in the shaft on account of lack of power. It has been stated by Mr. Hines, the electrical engineer of the Consolidation, that this hoisting equipment is believed to be the initial one of its type to be installed in the eastern bituminous coal fields; safety features are provided covering all contingencies for man, load and operating protection. The engine house is of fireproof construction—brick walls and steel roof trusses.

During the early development days of the mine the man and material hoist shaft was used as a temporary coal shaft also; the smaller headframe shown in Fig. 2 is at this shaft. A 22 x 36-in. steam-driven, double, first-motion engine, made by the Connellsville Manufacturing and Mine Supply Co., of Connellsville, Penn., was installed at the shaft and used to hoist coal among other purposes. A counterweight is used to balance the single cage and rope, and runs in an adjoining compartment to the cageway of the shaft. A temporary wooden trestle was built from this shaft to the railroad track to enable the coal hoisted to be dumped into railroad cars for shipment. This trestle is still in place and can be utilized for loading coal should there be an interruption to operations at the main shaft.

In the same building containing the man hoist engine is the power plant for the limited steam requirements of the plant. Installed originally for shaft-sinking purposes, it is continued as a reserve source of power. The steam pipe covering used at this plant is asbestos sponge-felted, furnished by the H. W. Johns-Manville Co. The 6 x 20-ft. Lepley reversible mine fan at present is driven by a 22 x 24-in. steam engine, both made by the Connellsville Manufacturing and Mine Supply Co. It is the intention to equip this fan with an electric motor which will be the prime motive power, the steam drive being held as reserve in case of failure of electric power. It is essential that there be no interruption to the operation of the fan at this mine. The fan was designed to force 300,000 cu.ft. of air into the mine against a total water gage of 3.6 in. Steam is generated at this plant in three 100-hp. water-tube boilers made by the Erie City Iron Works, of Erie, Penn. The exhaust from the fan and the hoisting engine goes through a heater made by the Pittsburgh Feed Water Heater Co., of Pittsburgh, Penn. The feedwater is handled by Snow and Smith-Vail pumps, while a Cameron is held for emergency use. Adjacent to the engine room and under the same roof is a substation; here is a switchboard and a converter to change the line alternating to direct current, the equipment being furnished by the General Electric Co. It is of practical interest to note that the Consolidation company has a number plate attached to every piece of machinery about its plants. In case of necessary repairs to or removal of apparatus from one location to another, the number permits of a definite record being kept of each operation in concise form.

There are few cases where a shop of some description is not an important part of coal-plant equipment. In sections remote from establishments where difficult repairs can be attended to promptly, it may be essential to have a shop at the plant where such work can be done satisfactorily—the size of the plant often influencing the amount of the investment in this direction. A view of the substantial brick building used by the Consolidation at Mine No. 87 for a shop, supply and lamphouse is shown in Fig. 6; it is 35 x 160 ft. in outside dimension and about 18 ft. in height.

The shop utilizes about half of this space and the lamproom about a quarter of it. At present machines are being installed; two underdraft forges made by the Buffalo Forge Co., of Buffalo, N. Y., an emery

FIG. 4. THE TIPPLE AT NO. 87 MINE FROM THE UPPER SIDE

grinder, by the Norton Co., of Worcester, Mass., a drill press, by the Rockford Drilling Machine Co., of Rockford, Ill., and a few other of the usual accessories to mine shops are in place. It is expected to add other machines to this equipment in time, such as lathes, a steam hammer and so on. Smithing, carpenter and machine work are done in this shop.

The miners are required to use an electric mine lamp on account of the presence of gas in the underground workings at Mine No. 87; the Edison permissible portable (Model C) has been adopted for ordinary use. The mining machine runners and the firebosses carry Wolfe safety lamps, the former setting these lamps ahead of their work when undercutting. The electric lamps used by the miners are kept in proper condition and all repairing is done by the company, a nominal charge being made to the miners for the use of the lamp. The miners leave the lamps at the lamphouse on coming out of the mine at the end of the day's work and call for them again before going down the shaft to commence work. Racks holding 100 lamps each are ar-

ranged for holding them when not in use, and all lamps are numbered so that each man gets his own. The lamp is so well known as to need little description here; the storage battery, attached by a "cord" to the lamp, is charged at night for the day shift men and during the day for the men working at night. One hundred lamp batteries are charged at a time with current at 100 volts, the rheostat (furnished by Mine Safety Appliances Co., Pittsburgh, Penn.) being kept at one ampere.

The batteries are regularly inspected and water and solution added when necessary; as a rule the batteries are filled with distilled water twice a week and the solution is changed every eight or nine months. It takes about eight hours to charge the batteries ($2\frac{1}{6}$-volt lamps). There is one man on each 12-hour shift to look after the charging of the lamps and to do the ordinary repair work, such as wire renewals, repairs on the headpiece, and so on.

In the group of buildings about the shafts is the sand-oil-cement house, constructed of tile and cement. An oil-storage system installed by S. F. Bowser & Co., Inc., Fort Wayne, Ind., is used and several grades of

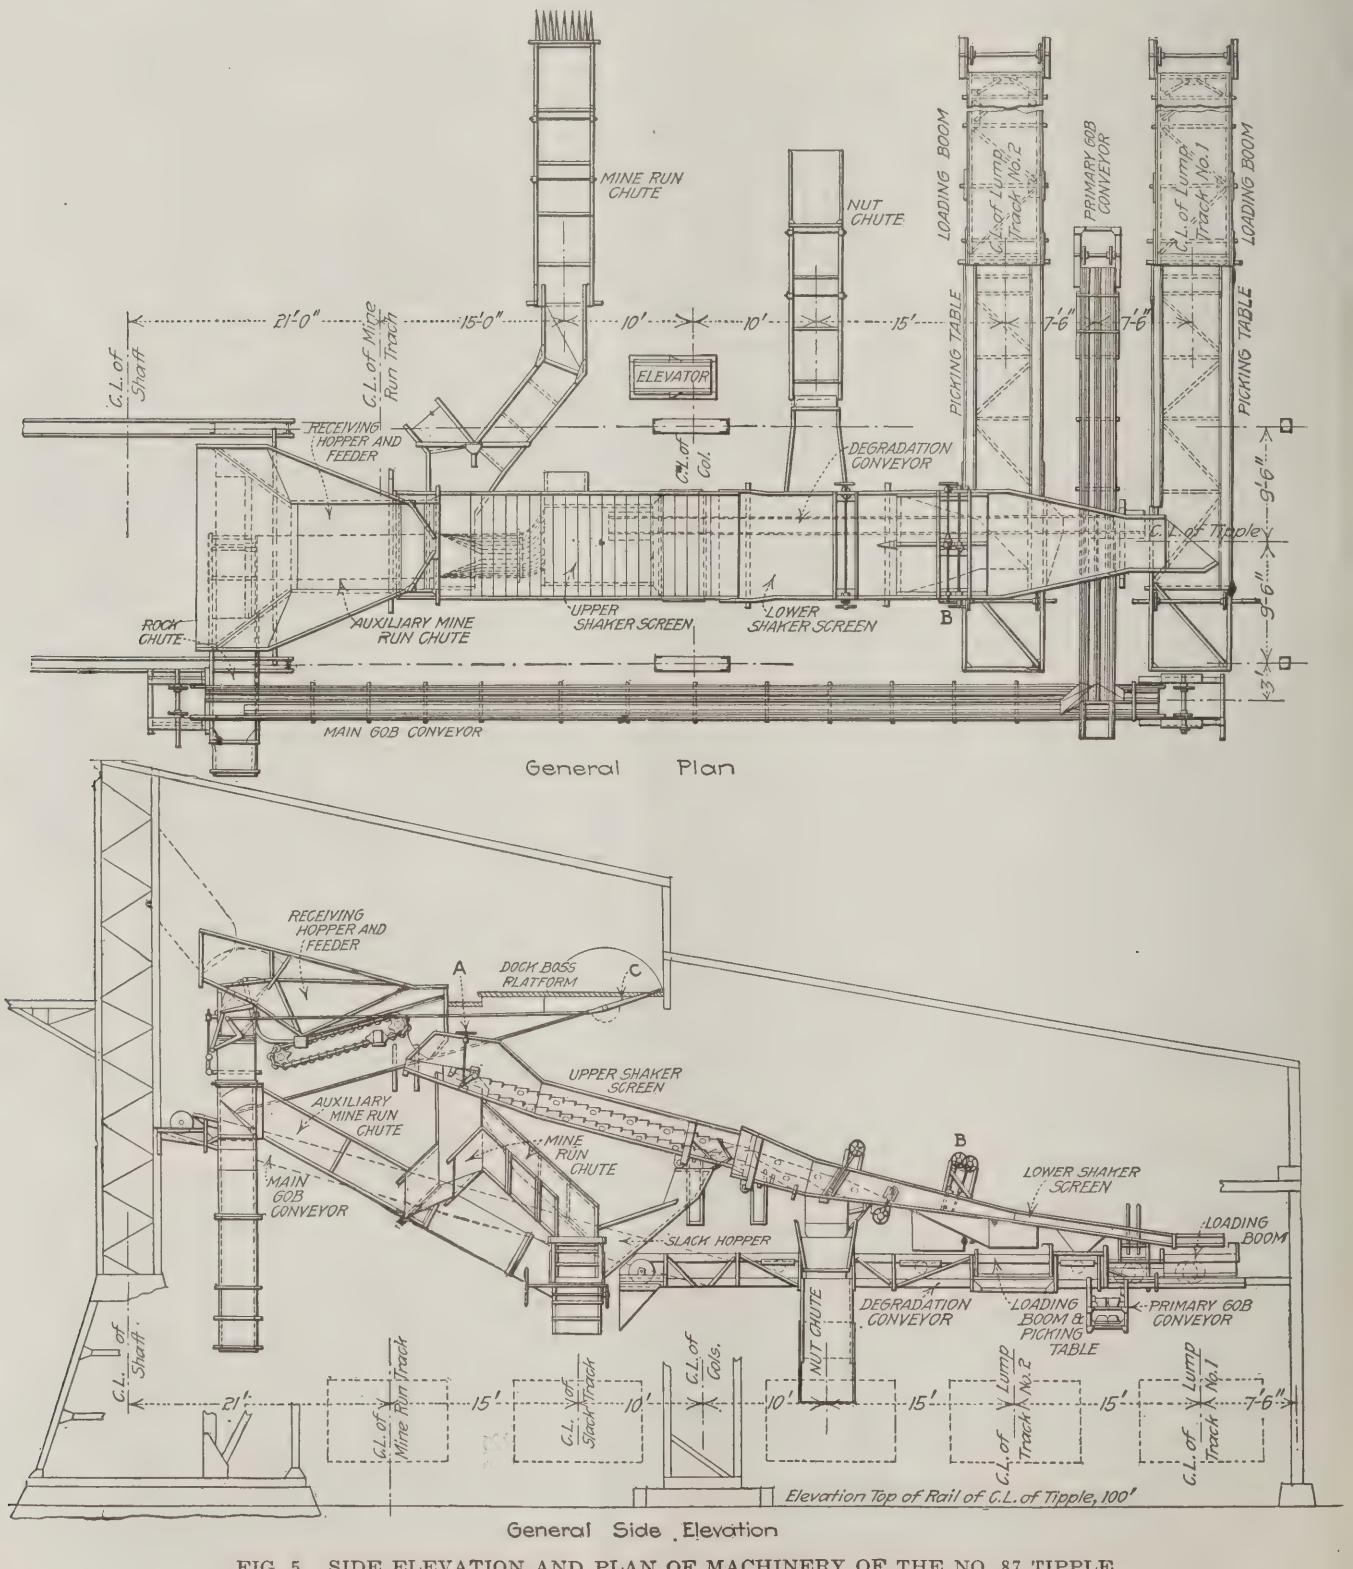

FIG. 5. SIDE ELEVATION AND PLAN OF MACHINERY OF THE NO. 87 TIPPLE

lubricants are kept—heavy black oil, for mining machines, a heavy engine oil and a lubricating oil for cylinders. On the mine cars "pit car oil," furnished by the Galena Signal Oil Co., of Franklin, Penn., is used. The main powder house is located up on the mountain side away from all other buildings, but the distributing house (10-ft. square) is adjoining the oilhouse. In this

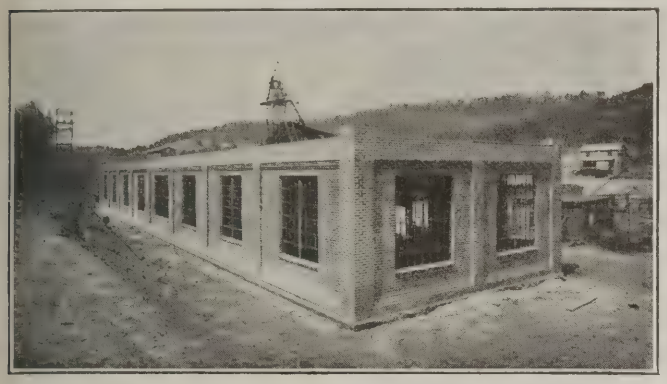

FIG. 6. SHOP AT THE NO. 87 MINE

latter house pigeon holes have been built around the sides of the room, one for each man. Monobel powder (manufactured by E. I. du Pont de Nemours & Co.) is used, and it is never necessary for any miner to take powder home as he can leave extra sticks in his pigeon hole at the distributing house and call for them again the next morning on his way to work.

(To be concluded)

Coal Operator and Central Station

The central power stations in Illinois have encountered many difficulties in the work of electrifying the coal mines along their transmission lines. The responsibility for the trouble rests with both the central stations and the coal operators.

The central stations have two difficulties to overcome. The first of these lies in obtaining the prospective customer's acceptance of the usual primary rate. This is really an arbitrary rate and is not made on any just basis. The usual primary rate is about $1.25 per month per kilowatt of maximum demand occurring during a definite interval of time. This charge is supposed to represent 15 per cent. of the cost of installing 1 kw. of station capacity to serve the consumer. The cost of 1 kw. is taken at $100, and 15 per cent. represents interest, depreciation and taxes or $15 per year.

Assuming that in normal times it does cost $100 per kilowatt to install the plant, and that the 15 per cent. charges are correct, is the central station justified in charging $1.25 per kilowatt of maximum demand, say on a basis of a 15-minute peak? The machinery is generally purchased on the basis of the capacity it will develop continuously, and not on its overload capacity for a short interval of time. The sum of the maximum demands of all consumers will greatly exceed the loads arising from these customers on account of the diversity factor, and because some are distinctively day loads and others night loads. Consequently, the maximum demand or primary charge should be reduced.

The central station will object to a reduction in the total rate due to cutting the primary rate, but this is unnecessary as the secondary rate could be increased to compensate for the loss. With such a readjustment both the central station and consumer would be benefited. The central station could more easily obtain the coal-mine load and the coal operator would not be required to pay the heavy primary charge when the mine is closed down because of labor troubles, accidents or lack of coal orders. The coal operator hesitates to sign the present power contract, carrying perhaps upward of $1000 a month primary charge, while he is confronted by the possibility of long idle periods.

The other great objection from the coal operator's standpoint is the disinclination of the central station to take the hoisting load without making the cost of the necessary machinery prohibitive. What I refer to is this: The central stations insist that large hoist motors must not be alternating current, but must be driven by special motor-generator sets which keep the line disturbance due to hoisting down to a minimum. Such equipment is generally excessive in cost. Where the change is being made from a steam to an electrically operated mine it is practically impossible to change over the hoist, with the result that the boiler plant cannot be entirely closed down; and the boiler plant is generally expensive to maintain.

If the central stations can get their power plants and transmission lines in such shape that large alternating-current motors can be used on mine hoists, they can greatly increase the coal-mine load on their lines.

On the other hand, the coal operator does not use the central station service to its maximum. Often only a motor-generator set is installed to operate locomotives and cutting machines underground, and no thought is given to the operation of the machinery on the surface. It is not unusual to see long, leaky, uncovered steam lines serving uneconomical engines for operating tipple machinery, car pullers, fan, shops, pumps, etc. The motor-generator set is probably operating under the lowest secondary rate, consequently if these engines were replaced with motors they would operate on the low rate, which would be greatly below the cost of fuel alone for running engines.

The central stations must educate the operators along these lines. They have not completed their task with the electrification of the mines, as the operators are liable to object to the payment of the power bills, which they really believe to be excessive. This is due to the fact that the power bills are payable on the first of the month and there is no question as to their amount. The cost of operating the steam-driven units now placed did not show up with such regularity, if at all. The coal burned under the boilers was probably only estimated—and greatly underestimated. The price probably was charged at the cost of production in place of at the selling price, and the cost of labor charged to other items where it did not show up as operating expenses against the small engines.

I have often heard the remark made: "Oh, it doesn't cost us a cent to operate that engine. It can't be noticed on our boilers, and we don't need any additional men as we need several around on the top anyway." Perhaps a dozen such small engines are employed at one plant. It devolves upon the central station to prove that it costs excessively to operate small engines.

American Opportunities in the Foreign Coal Trade

THE article printed below appeared in a recent issue of the *Colliery Guardian*, of London, England. It contains so concise an analysis of the conditions surrounding the exporting of coal and the possibilities of the United States obtaining a hold on foreign coal markets, that all who are interested in the export coal trade should read it. Although treated from the British point of view, there is still so much of truth and inherent sound logic in the article that it has been reproduced in its entirety.

IT GOES without saying that coal exporters in this country [England] are apprehensive just now as to the imminence of a concentrated effort on the part of United States coal operators to capture our pre-war markets. American competition has been heralded at various times in the last fifteen years without anything very serious happening to menace our position in Europe or South America, which are for us the principal zones of enterprise; but there can be no harm in considering whether the events of the past four years have added substance to the tenuous visions of the past.

A European Commission appointed by the United States Fuel Administration has just recrossed the Atlantic, following an investigation of the fuel situation in Europe. Their report, after enunciating the somewhat platitudinous statements that Europe is short of coal, and that fuel scarcity, creating unemployment, provides a fertile field for Bolshevism, records the fact that, whereas the production of Great Britain has fallen from 287,000,000 tons in 1913 to 230,000,000 tons in 1918, the output of the United States in the same period has increased by approximately 100,000,000 tons; further, that there is a considerable demand for American coal in Europe at the present time.

American Coal Output Increases Rapidly

It would be unwise to obscure the fact that the coal production of the United States has increased phenomenally since the opening of the present century, while that of the United Kingdom has done no more than preserve a rather unstable equilibrium; at the outset of that period we were still the world's chief producer of coal; now the single State of Pennsylvania produces more than we do. The moral of that is that a day must come sooner or later when British coal in many quarters of the globe will be supplanted by American fuel, even when allowance is made for the vast industrial development of America and her panoply of raw materials. But it is not easy to decide whether the war has precipitated that situation or not.

At the close of 1917, the United States was threatened with a fuel scarcity as serious as ours, but this was largely the result of car shortage, and, by the introduction of various measures, including "heatless Mondays," the situation was pulled round. In 1918 the output was 689,652,110 short tons, or an increase of 6 per cent. over 1917, and it was proved conclusively that the ability of American mines to produce fuel was greater than the ability of American industries to consume it. In a similar crisis, we more than failed to preserve the *status quo*, but the conditions were essentially different. There was a shortage of labor in America, but in no sense so acute as that from which we suffered in this country; wages rose in both countries, Pennsylvanian miners of the higher grades being able to earn nearly $8 per day in recent months, but this is counterbalanced to some extent by the greater per capita output—in 1917-18 the individual output, in West Virginia, including inside and outside labor, was just over 900 tons per annum, in the Pennsylvania soft-coal region over 1000 tons, as compared with 240 tons in British mines; in both countries the Government restricted selling prices and controlled distribution; there is this point, however, that in the United States every encouragement was given to operators to increase the productive capacity of their undertakings by the adoption of labor-saving machinery and large-scale remodeling of plants; whereas, in this country, Parliamentary and financial restrictions impeded even the work of normal maintenance.

American Operator More Economical

According to what has been known as the Peabody plan, coal operators in the United States were left very largely to deal with the problems of intensified production, so far as their internal affairs were concerned, and it has proved an undoubted success. It is too early as yet to gage the enduring effect of Government intervention in this country.

It is not an easy matter to determine the increased cost of production in America; according to the estimates of the Geological Survey the average value of coal at the mine rose from $1.32 per ton in 1916 to $2.25 per ton in 1917. In 1918, it is probable that the operation of a state-regulated basis may have kept pit-head prices at a level not very much in excess of the figure named. The cost of production has undoubtedly risen, but, due to the increased output per head and the introduction of measures to promote intense production, the ultimate increase may not have been very great. It is only fair, in making comparisons between Great Britain and the United States, to realize that the American coal operator has much greater margins for economy; the high output per head is largely attributable to the fact that there has been no imperative necessity for economy in mining methods; so much is admitted by American mining engineers, who do not make the claim to a monopoly of efficiency which some of our own pessimists attribute to them.

The present position is that stocks of coal in the United States are abundant, and there are signs of an abatement of the internal demand, due partly to the lessened requirements of the navy, and the rail-

roads and munition works, although great activity is anticipated in the iron and steel trades during the present year; labor is not too plentiful and may remain so, for the reawakening of national life in Poland and the other Slav states, from whom the United States has in the past drawn a large proportion of its coal miners, may not only retard the wave of immigration, but divert some of the existing labor to their native soil; during the war period the number of mines in operation increased by over 75 per cent., and it is calculated that overproduction during the present year may amount to as much as 100,000,000 tons; although this surplus will probably not be realized, it is clear that an outlet could only be found for it abroad; the regulation of prices may be relaxed, but there appears to be no intention for the present to abolish the price and zone regulations inaugurated in 1917, and it is not likely, in any case, that prices will return to their pre-war level, for in 1913 and 1914 the industry was suffering severely from overproduction and unremunerative prices.

In the twelve months ended June 30, 1918, exports of United States coal amounted to 21,051,979 tons, or 1,422,888 tons more than in 1916-17, but this increase was due to the fact that exports to Canada—her best customer—increased by 3,607,146 tons for the year; otherwise the expansion has not been very great. In 1911-12, 276,467 tons of American coal were exported to Italy; in 1912-13, 33,264 tons; 1913-14, 776,422 tons; 1914-15, 1,628,279 tons; 1915-16, 2,797,506 tons; 1916-17, 1,099,508 tons; 1917-18, 201,220 tons. In all, the United States shipped only 355,314 tons to Europe in 1917-18, as compared with 1,635,902 tons in 1916-17, and 3,591,281 tons in 1915-16. To the South American countries the decline in exports last year was also heavy; the Argentine took 247,613 tons as against 706,776 tons in the previous year; and Brazil 625,374 tons as against 156,059 tons. South America has been thrown back very largely upon native resources, the curtailment of imports of British fuel being equally great; in both cases the causes were the same—export restrictions and shortage of tonnage.

Important Factor Is American Merchant Marine

But there is one more factor, and it is one of considerable weight, namely, the possession by America today of a considerable merchant marine for the first time since the Civil War. It is estimated that by the end of this year the United States will own some twelve million tons of shipping. This new shipping will require a large increase in bunkers even if a great number of the new ships are constructed to burn oil; but the possibility of using it to capture our markets is qualified by at least three considerations; first, an enormous demand for the freightage of American goods intrinsically more valuable and profitable to the shipper than coal; second, the lower ballast value of American coal owing to the trade of the country being essentially an export and not an import trade; and third, the existing business connections of British firms. In reciting these factors it is not necessary for our purpose to emphasize the longer haul that has to be borne by, say, New River or Pocahontas coal before it can be put on board ship at tidewater, because this is offset by a lower price at pithead, and a lower railway rate per mile, so that it is probable that a good steam coal from these regions can be shipped f.o.b. at not more than $6 per ton.

At one time there seemed to be a prospect that America would oust us permanently from the South American market, but this was not realized even during the war, for eventually, in June, 1918, the United States Shipping Board, which two months earlier had taken over all free tonnage, concluded an agreement with the British government by which we agreed to keep out of Rio, and United States coal exporters out of the River Plate market. The latter was chiefly supplied with American coal—in British bottoms—but American exporters of experience are not too sanguine as to the success of a South American campaign in the near future; on that and other accounts the Administration has been loaded with abuse, exporters blaming the restrictive rates and licensing system instituted in 1917 for their inactivity, but it is only right to remember that British exporters have been called upon to suffer the same and greater evils ever since the outbreak of war.

Hopes and Illusions

The brutal fact is that, notwithstanding the alluring reports circulated by diplomatic and so-called trade emissaries abroad, the American coal trade, although its worship for the word "organize" is almost uncanny, has a lot to learn in regard to conditions prevailing in foreign markets, the fastidious likes and dislikes of customers, and other details which profoundly affect trade relations. In the past the Sherman Anti-Trust Law has been severely repressive of coöperative enterprise. The National Coal Association, an important war-time organization, is now planning the formation of an export association to develop a market for American coal abroad, the project being to pool all deliveries at tidewater and to conduct the further stages on syndicate lines.

Formerly it was contrary to Federal law for merchants to combine for such purposes, but the Webb-Pomerene Bill recently adopted in Congress concedes these facilities. At the same time, there are indications that there are groups of shipping companies that are willing not only to undertake the transportation and docking of the coal, but to offer financial facilities. A difficulty here is to distinguish between trade of a purely temporary character and cases where the exporter proposes to establish a permanent connection. The question of credit is one that has greatly hampered the American coal exporter in the past, but even before the war American banks had been enabled to establish branches in South America and elsewhere; and a large concern, known as the American International Corporation, exists for the definite purpose of financing shipments.

The present position of the United States, as the principal creditor nation, may ultimately prove of great advantage to merchants in their dealings abroad; for the present, however, the great accumulation of gold in the United States is prejudicial to the export of coal, as it will be preferable to pay for imports of such manufactured goods and raw materials as may be required in cash rather than in kind. Yet it is stated that Congress intends to raise customs duties,

in order to reduce importation, and thereby protect home industries. In that case it is probable that the rate of exchange will become even more unfavorable for the exporter; at present there is a premium in Paris of about 5 per cent. on New York drafts, and in Italy it is not less than 10 per cent. But when this excess of capital is dispersed, as it probably will be, by large investments in foreign industrial operations, the very existence of these holdings may assist to some extent in the creation of markets for essential materials.

It is well that we should be alive to such developments, but in the meantime there seems to be every prospect that British exporters will hold their own, especially where the markets are also the centers of an important trade with this country in food supplies, for in such cases it is an imperative necessity to keep open the channels of our import trade. Community of interest between exporter and importer makes a formidable combination, although it may, in this case, have been affected by the extinction of British investments abroad. But, for the present, the necessity to pay for imports by means of exports, rather than by means of interest on holdings in the country of origin, is a distinct advantage to the British exporter. What we probably shall see is a large extension of the American coal export trade through British agencies, a movement that had already gained momentum when the war broke out. Beyond that, it is indubitable that a day will come when the outer ramparts of our trade will be driven in—when British coal will not go, except in ships' bunkers, beyond the Suez Canal. It depends very largely upon the attitude of the working miner as to whether that day comes sooner or later.

That is in the womb of the future. For the present it is probable that the distribution of coal overseas will be a matter more or less of arrangement between the United States and British governments, based largely upon international and humanitarian considerations; the arrangement in South America being of this nature, as is the consignment of 100,000 tons of American coal to Holland.

At the present time, with the coal fields of Europe working far below their normal capacity, it is eminently necessary that full advantage should be taken of America's ability to make good the shortage, but it is equally important that no false sentiment of goodwill should tempt us to surrender permanently a trade that is in the highest sense a necessity to our existence. The greatest danger is that the shortsightedness of the British coal miner may encourage the foreign consumer to seek security by an alliance with the American producer; the latter then would possess just those advantages which have hitherto been ours.

USUALLY THE CHIEF ENGINEER of a large coal company is a man with a sufficiently broad experience to be able to write out practical specifications. However, unless these specifications are carefully prepared, bids submitted on them are not apt to be satisfactory. In one instance a proposal was made on so-called specifications and it amounted to approximately $20,000. On looking over this bid, the company decided to call in an expert engineer to go over the plans. The result was that another bid was asked for and submitted which resulted in a saving of over $6000 on the initial cost.

Did You Ever See a Ladder Like This?

The National Safety Council asks in a bulletin: Did you ever see a ladder like this? The answer is: Lots of them. The cross sticks are weak and shaky, the treads are many of them extremely uneven, the spacing of the rungs is unequal and too great, the ladder has been lengthened out in a manner none too safe; some of the rungs are so inadequate that the nailing of them in place inevitably has split and so weakened them. Play safe and discard all such ladders: A dozen different kinds of accidents may occur in the use of them. "Different accidents," we may call them, but one and all they are alike in one particular. They are all unnecessary and avoidable. Says the Safety Council: "If you use a home-made ladder make it safe. If you see a rung broken or ready to break, fix it or tell the foreman." It does not pay to take chances.

NEVER USE A LADDER LIKE THIS

Legal Department

RIGHT TO ROYALTIES UNDER CONTRACT—Where an owner of all the stock of a mining corporation, which had a five years' lease on certain coal property, transferred the stock in consideration of the payment of a tonnage royalty of seven cents on all coal mined under the lease, he was not entitled to royalties under a new lease granted at the expiration of the old one; the new lease not being intended as an extension of the old one. (Lathrop vs. Clemow, 68 Pennsylvania Superior Court Reports, 116.)

ADVERSE POSSESSION OF COAL IN PLACE—One who takes a deed to the surface of land with notice that the underlying minerals have been conveyed to another can acquire no adverse possession to the minerals by reason of his occupancy of the surface under claim of ownership. Adverse possession of underlying minerals can be initiated only by working them or by exercising some other act of dominion manifesting a purpose to claim them. (United States Circuit Court of Appeals, Fourth Circuit; Midkiff vs. Colton; 252 Federal Reporter, 420.)

OPERATOR NOT LIABLE FOR MINE FOREMAN'S NEGLIGENCE—No recovery can be had against a Pennsylvania operator for death of a miner attributed to neglect to provide him with an adequate supply of posts to prop roof, where it does not appear that the mine foreman ever ordered props from the superintendent that were not promptly furnished, or that the operator's attention was otherwise drawn to any shortage of props. In such case the operator is protected by the provisions of the statute which imposes upon the mine foreman the duty of directing and seeing "that every working place is properly secured by props or timbers," and of ordering the mine superintendent "to keep on hand at all times a sufficient quantity of materials and supplies required to preserve the health and safety of the employees." (Musin vs. Pryor Coal Co., 68 Pennsylvania Superior Court Reports, 88.)

Breaking of Cable in Protection Shaft

By Robert Dunn
Victoria, B. C.

SYNOPSIS—*A breaking rope in Protection shaft caused a heavy loss of life. What caused the cable to break? Tests conducted in Montreal would indicate that a lack of adequate lubrication, particularly in the hemp center, leaving the cable exposed to the attacks of water both from within and without, had much to do with the failure of the rope.*

WHAT was the caus of the breaking of the cable in Protection shaft, Canadian Western Fuel Co., Vancouver Island, B. C., on the 10th of last September, when 16 miners were hurled to death? Is it possible to adopt preventive measures that would make a repetition of such an accident impossible, except through non-compliance with regulations or carelessness in other respects?

These are two questions with which a coroner's jury holding an inquest into the deaths of the aforementioned coal miners at Nanaimo, B. C., are dealing. The inquiry is being thoroughly prosecuted as a result of the keen interest manifested by the Provincial Department of Mines. At the sitting on Dec. 16, William Fleet Robertson, Provincial Mineralogist, placed in evidence a report of investigations he had made at the laboratories of McGill University, Montreal. This document contains information of moment to all concerned in the use of wire cable in mining operations. The details given covering tests of the broken rope, and the conclusions reached, it is believed, will cause some radical changes to be made in present methods of inspection.

As to the cause of the accident under examination, Mr. Robertson's findings are contained, in summary form, in the following excerpt from his report:

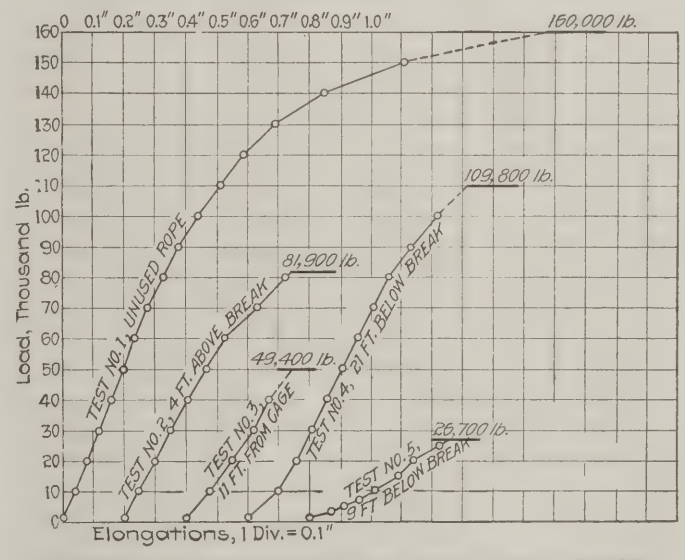
The failure of the cable was, in my opinion, entirely due to the oxidizing of the wires, chiefly internally, caused by apparent lack of any internal lubrication, leaving the wires exposed to the action of a more than normally corrosive water and a humid atmosphere.

The hemp core, which under a sufficiently effective lubrication system would serve as a reservoir of oil to keep the wires oiled and protected from corrosion, not being supplied with oil, became a reservoir of moisture and so hastened the corrosion of the wires.

It is a well-known fact that if rust gets started in a steel structure such rust will continue despite any surface application of anything that may exclude the atmosphere.

Hence only a thorough soaking of the hemp core with oil before it is installed and a frequent renewal of the oil supply would be necessary to ward off corrosion.

The fact that the tests showed the cable to be more corroded in certain parts than in others, and these not in any regular procession, may be accounted for by local conditions in the shaft, of which I have no knowledge.



A reference to the sketch showing tests will show that the section of the cable about 4 or 5 ft. from the fracture broke under a load of a little over 13 tons, and it stands to reason that the rope at the fracture had a lesser strength.

The weight of the empty cage is given by the company as 4358 lb.; the rope, 179 ft., weighed about 540 lb.; sixteen men at an average of, say, 170 lb., 2720; making a known dead load of 7617 lb., or approximately 4 tons.

Mr. Robertson gives it as his understanding that the rope broke at a point which, at the time, was passing over the sheave and proceeds to say that "when a cable of this description passes over a 10-ft. sheave, it is by the bending subjected to an additional 9360 lb., or, say, roughly, 5 tons. This, in addition to the dead load as given above, would give a stress in cable, if traveling slowly, of approximately 9 tons, which approaches so near to the breaking stress shown in Test 5 (described hereinafter) that it is scarcely necessary to assume extraordinary rough handling by the hoistman to account for the break.

"As an indication that this sort of interior corrosion is not confined to the case in hand," Mr. Robertson produced "a piece of 1¼-in. cable from a Sudbury mine which was tested at McGill University in my presence. It broke at 58,600 lb., whereas the new cable had a breaking strength of about 128,000 lb. I think you will agree with me that this cable shows but little deterioration discernible, externally, whereas in the broken end, also exhibited, the internal corrosion is excessive."

Before proceeding to give details of the interesting experiments carried out at Montreal under Mr. Robertson's supervision, it should be explained that he was furnished at Nanaimo with all the faulty cable which, for convenience, is divided into three parts: (a) That part which was constantly on the hoisting drum in the engine room; (b) that 100 ft. including the upper end of the fracture and extending upward and (c) that 100 ft. including the lower end of the fracture and extending downward to the cage. He also had the spiral springs designed to bring the safety clutches into action, a jar of water collected as it fell in the Protection shaft, and a bottle of black oil of similar character to that used in lubricating the cable. His directions were

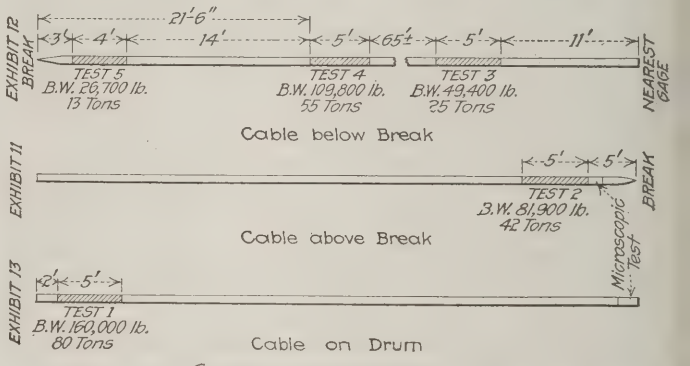
GRAPHS OF THE PORTION OF THE CABLE TESTED

to submit these "exhibits" to "the most critical physical, chemical and microscopic tests practicable in Montreal," with a view, of course, to establishing definitely and beyond cavil the cause of the break.

The result of the tests to which the cable was subjected is graphically illustrated in the accompanying illustration. Of them Mr. Robertson says:

Test 1—This piece of cable [that taken from the drum] showed only very slight wear and only on the outer wires, possibly caused by pressure on the drum. The individual wires were bright and free from rust. The cable was practically as good as new, and had been lubricated, grease oozing out as the strain was applied. The test piece taken was approximately 36 in. between the grips. The load was applied in successive increments of 10,000 lb. each, the elongation of the specimen being taken for each increment.

The elongation for each 5-ton increment was 4/100 in. up to 70,000 lb., increasing gradually until at 120,000 lb. the elongation for the last increment was 8/100 in.—the total elongation under this load being 59/100 in. At almost 130,000 lb. the elastic limit of the cable seemed to be reached and the cable broke under a load of 160,000 lb., after sustaining such load for a minute or so, when three strands broke simultaneously a few inches below the upper grip.



The pull being continued, the other three strands broke near the lower grip. The breaking strength of cable was 160,000 lb., or 80 short tons. As a check and confirmation of this test a 24-in. piece of cable adjoining the test piece was unwound—the individual wires somewhat straightened—and six of the larger wires and three of the smaller wires from each strand were submitted to a tensile breaking strain. These wires showed remarkable similarity in strength. The wires of average diameter of 0.1255 in. had an average strength of 2540 lb.; the wires of average diameter of 0.085 in. had an average of 1165 lb.

The aggregate strength of all the wires comprising the cable, if pulled straight, would be 179,100 lb. The strength of the cable, therefore, was about 89.35 per cent. of the strength of the aggregate of the wires, a result considered as indicating a well built cable. The tensile strength of the steel in the wires would be equivalent to about 208,000 lb. to the square inch. This result, taken with the uniformity in strength of wires, indicates an excellent quality of steel in the cable.

Test 2—This was conducted on sections of cable immediately above the fracture. The test piece was cut starting about 5 ft. above the tapered end of the fractured cable. The exterior showed a certain amount of wear on the outer wires but not at all serious. No broken or torn wire ends were observed on the surface in the whole length of the piece. A serious amount of rust was observable on surface wires. In opening up the end of the test piece, in preparing it for the grip, the small interior wires were found to be badly rusted and eaten away, so much so that several of them were found to be completely eaten through. None of the larger (0.1255 in. diameter) outer wires were eaten through—but they also were badly corroded—a rough estimate being that the steel in these wires had about half the sectional area of similar wires in Exhibit 13 [the good rope].

The cable and the core showed no indications of having been lubricated—both were dry and dusty. This test piece [tested similarly to the former] showed very even elongation for each successive increment of 5 tons in load—up to 60,000 lb.—at about which point the elastic limit seemed to be reached. Under a load of 81,900 lb. four strands of the rope broke, the break extending 12 in. below the grip. In breaking clouds of dust were given off, the doors of the building having to be opened to clear the air, indicating the interior to be very dry, with no indications of having been oiled. The two remaining strands broke under load of 21,000 pounds.

Test 3—This and the following two tests were made on three separate pieces of the rope from the fracture down toward the cage. The test under consideration was of a piece cut 11 ft. from the end nearest to the cage. It was seemingly uninjured by its fall with the cage. It was not untwisted at all and there were no projecting or loose wires on the surface. The surface was somewhat worn and was corroded to at least half

WHERE TEST PIECES OF THE CABLE WERE SECURED

section of the externally visible wires. In the portion opened for the grip several of the small wires were found to be corroded completely through, as were a few of the larger wires. The load was applied as in previous tests. With each 10,000 lb. increment of load the elongation was practically constant up to 40,000 lb., being about 0.07 in. for each increment. At about 40,000 lb. certain of the interior wires were heard to break. At 49,400 lb. the cable broke at about 3 in. below the upper grip. The center core was absolutely dry and dusty, and large quantities of rust dust were given off in breaking.

Test 4—This test piece was cut 21 ft. 6 in. below the fracture. The cable showed but slight wear, but was much corroded both on surface and interior wires, but as far as could be seen few if any of the wires were actually eaten through. No evidence of lubrication was visible in the interior of the cable. This piece was tested as were the former. The elongation for each 10,000 lb. increment was constant at about 5/100 in. up to 80,000 lb., which was about the elastic limit. Under a load of 106,000 lb. some of the interior wires were heard to break. At 109,800 lb. the cable broke, two strands parting about 6 in. below the upper grip. Subsequently the remaining strands were broken by reapplication of the load. The third strand broke under a load of 55,000 lb.; the fourth under a load of 55,400 lb. and the fifth and sixth under a load of 43,700 lb. Three strands broke near each end of the test piece.

Test 5—This piece was cut at 3 ft. below the point

of break. It did not appear to be damaged by the fall. The rope was still tightly twisted and but slightly bent, not enough to materially affect it. This piece was badly corroded, so much so that even on the surface a number of the wires were seen to be completely eaten through and could be picked out with the fingers; but none of the ends projected. In the interior of the cable one of the sub-strands was completely cut through by erosion. There was no indication that the rope had even seen oil.

The condition of the test piece was evidently so bad that the load was applied in smaller increments than in other tests. At 2600 lb. load wires were heard to break in the interior. The successive loads applied were 3000, 5000, 7000 and 10,000 (when elastic limit was reached), 20,000 and 25,000 lb. At 19,500 lb. a number of wires were heard to break and at 22,000 lb. more wires broke. At 26,700 lb. load three strands parted 12 in. below the grip. Three remaining strands broke at 8800 pounds.

The cable in question had been in use for three years. It is described as being originally a first-class cable in every particular, well made and of excellent material, of Lang's lay build and apparently up to specifications.

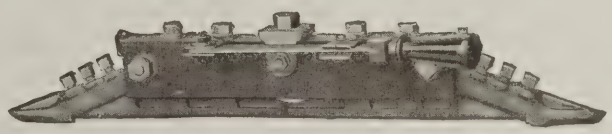
The amount of rust visible on the surface was serious and showed when the cable was dry, but if the cable as it hung in the shaft was dirty, an inspection by passing the rope through the hand or against a stick would fail to reveal the defect in the rope.

In a shaft where the cable was subjected to heavy and constant work, the wear on the external wires would probably be so great as to wear certain strands through, thus producing projecting ends; and these would be the first indications of deterioration of such a cable. The hand test might then be of value. But in the Protection Island shaft the mechanical wear on the cable was slight, the failure being internal, hence not discernible by the method of inspection in vogue.

Concerning the spiral springs designed to bring the safety clutches into operation these were of excellent quality, capable of a safe extension of about 30 per cent. of their length and having a pulling power when so extended of about 1250 lb. It may be observed here that tests since made at the Canadian Western Fuel Co.'s yards at Nanaimo have demonstrated that such springs and clutches do not give satisfaction on a descending cage, although brought into successful operation on an ascending cage suddenly released.

The oil used in lubrication is declared to have been of a character non-injurious to the steel. Concerning the water, Mr. Robertson says: "There was no free acid in the water that would dissolve the steel, but the water was of such composition as to rust the steel more rapidly than pure water would. It would also be apt to wash off any external lubrication of cable faster than would pure water."

[No verdict had been reached by the coroner's jury at the time the foregoing article was written, and as a matter of record the subsequent findings of the jury empanelled to inquire into the cause of the death of the 16 coal miners is given herewith: "We [the jury] find that the said men came to their death by descending on a defective cable, which broke, owing entirely to the oxidizing of the wires, chiefly caused by apparent absolute lack of any internal lubrication, leaving the wires thus exposed to the action of a more than normally corrosive water and a humid atmosphere." The jury recommended the appointment of an expert inspector of hoisting ropes, cages, safety catches, etc., and that legislation be enacted whereby under such abnormal conditions as obtained in the Protection shaft no new hoisting cable be retained in service longer than some reasonable time to be determined by the Department of Mines.—EDITOR.]



Mine Section Insulator with a Switch

In mines every cross-entry should have a section insulator placed in the trolley wire on the tangent as close as possible to the main entry. As most cross-entry trolley wires are used only a part of the time it would increase safety if current were cut off from it when it is not in use.

A common practice is to use a section insulator similar to that shown in the accompanying illustration. With certain types of section insulator having no switch attachment it is necessary to have a knife-switch connected in the circuit so that the cross-entry trolley wire can be energized. Such a knife-switch should be mounted in a box to protect it from moisture and dust.

It will readily be seen that this arrangement requires a considerable amount of labor and material. It also has other disadvantages, as the locomotive may get stalled with the trolley wheel on the insulated part of the section insulator while pulling a load. Considerable delay will be experienced in such a case unless there is insufficient room to turn the trolley pole. It is often necessary to detach several cars in order to enable the locomotive to pass the dead section in the trolley.

A section insulator should not permit of any leakage whatever if the switch is open. Its construction, as a

COMBINATION SECTION INSULATOR AND SWITCH

whole, should be mechanically strong, yet not so heavy as to add unnecessary weight in case the local conditions are such that it cannot be supported direct from the mine roof. Two supporting lugs with longitudinal adjustment are preferable. Where conditions do not permit of using two supports and space is limited, a swivel boss in the center is highly desirable. The runner of the switch should never obstruct the passage of the trolley wheel, regardless of whether the switch is open or closed.

A metallic runner with air insulation has several advantages. It allows uniform wearing and no parts require renewal. Where treated wood or fiber is used considerable arcing when breaking the circuit takes place. This eventually increases to such an extent that the runner parts have to be replaced quite frequently.

The switch should be independent from the runner and of such section that it will permit a heavy current to be carried without heating the section insulator at any point, as this may damage the insulating qualities of the device.

Direction of current flow in a mine varies and a switch should be made so that it can be opened either right or left hand. The illustration shows a switch that can easily be changed from a right- to left-hand throw by loosening up the machine bolts and interchanging the break jaws with the hinge jaws. Changes of this nature can be made in the mine quite easily. When the switch is open, the break jaw should always be the live terminal. This can be accomplished by interchanging the hinge and break jaws as mentioned above.

The Mindanao Coal Mines

By Monroe Woolley
San Francisco, Cal.

SYNOPSIS — *The Philippines are rich in coal but Mindanao appears to have more extensive fuel deposits than the other islands of the group. These deposits are not now worked to any great extent, but it is hoped that ere long native coal will replace Japanese fuel at Manila and other ports of call for steamers following the routes of world commerce.*

AN AMERICAN mining engineer who has had much experience in China and other Far Eastern countries, after making an extensive investigation of the coal fields in Mindanao, Philippine Islands, pronounced the deposits the greatest in Asia. This means not only a great deal to Philippine industry, but to the world at large, particularly to the United States.

Perhaps the most extensive deposits so far known in Mindanao are located on the Sibuguey peninsula. The National Coal Co. has recently finished an exhaustive survey of these rich fields and is now rapidly preparing to develop its holdings there. The Philippine insular government holds 51 per cent. of the stock in this company. The peninsula contains about 100 square miles of surface underlaid with rich deposits of coal.

The National Coal Co. is confining its present activities to a tract about 10 miles in extent that is especially rich and the product of which can be marketed at a minimum cost. This tract lies inland from Taba Bay and is not far from the Sibuguey River. For eight months of the year this stream is navigable as far as the coal fields, and until the company sees fit to put in its own transportation lines the river will be used for getting the output to market.

Preliminary to development on a larger scale the company is putting out something like 100 tons per day. Before it can materially add to its output from its holdings the company will be compelled to import a considerable amount of machinery from the United States, especially railroad material to get the coal to the coast ports, as well as mining machinery to get it out of the ground. It is known that the river cannot be relied upon continuously, as it is navigable only for a portion of the year. Furthermore, it is remote from the outlying fields belonging to the company. Hence, when development reaches a more extensive scale, as it soon will, railroads must supersede the stream. The company has already bought considerable second-hand equipment from the railroad companies in the islands, such as engines, boilers, pumps and some other apparatus.

The preliminary surveys of the Mindanao fields show considerable amounts of anthracite, especially at the northern end of the National Coal Co.'s tract. Here a bed of this coal 13 ft. thick has been uncovered. But as the islands have no use for anthracite, at the present time, no effort will be made just now to mine this fuel.

Near the middle of the National company's tract there is an excellent vein of bituminous 6 ft. thick. Experiments with this product show the coal to be a good coking quality. It has tested out far ahead of the Japanese coal long imported into the Philippines. There has also been discovered a bed of non-coking soft coal that appears to be about 6 ft. thick and of considerable extent.

Mindanao is said by soldiers who have served there and who have traveled widely over the island to be a veritable mine of coal. In many remote places, almost

DIAMOND DRILL AT BATAN COAL MINE

wholly unvisited by white men, coal is said to crop out of the earth everywhere, and no doubt Mr. Bryan, when he was advocating the retention of Mindanao as a coaling station, in event the Filipinos were given their independence, was aware of this mineral wealth.

A new bed of good steaming coal has been discovered in Albay Province, southern Luzon. A company is preparing to invest $150,000 in modern mining machinery. Vicente Mardigal & Co., the largest coal dealers in Manila, are said to have made an offer to the promotors of this new field for their interests, but it is believed that whatever operations take place will be under the direction of the National Coal Co., as provided by Philippine laws.

The government tried to mine coal from the Batan Island fields in the Gulf of Albay some years ago, but the earlier operations failed. The mines had to be abandoned because it was claimed the formations found would not resist the water pressure, and the mines could not be sufficiently timbered to permit of operation. The new bed is said to be on a higher elevation and is protected from water by a rock formation. The fact that this is absent in most coal regions of the Philippines has already kept several projects of good promise from development.

At present there are two coal mines being operated on the Island of Cebu. One is at Uling, south of Cebu City, and the other at Banao, to the north. At each of these places it is reported that the output is about 30 tons per day and all of the coal mined is readily disposed of. Mr. Betts, who was formerly American governor of Albay Province, is operating a mine near the old government project on the Island of Batan, near the port of Legaspi in the Gulf of Albay. The output of the Betts mine is only about 25 tons daily and the Manila R.R.'s Legaspi line consumes the entire output.

A corporation with a capital of half a million pesos (a quarter of a million dollars), has been organized in Iloilo, capital of Panay, for the purpose of mining coal at Escalante, on the Island of Occidental Negros. This organization is known as the Negros Coal Co. This company at last report had not yet produced coal, but was preparing to do so.

It is a lamentable fact that although the entire Philippine archipelago, particularly Mindanao, is rich in coal deposits, it has, nevertheless, always been necessary to import coal from Japan or China. The American army transport service has always had to make Nagasaki a port of call for coal, and these ships are kept busy carrying coal for their own use back and forth between Nagasaki and Honolulu. Besides, the Philippine government, and many commercial concerns in the islands, import thousands of tons annually from Japan, when, as a matter of fact, there is literally "coal to burn" right in the Filipino's back yard.

The Filipino has the biggest coal fields in Asia, but he has been a long time finding it out; and when he did discover the great truth he was not as energetic in developing his natural wealth as he might have been. Yet it is not altogether the fault of native capitalists

MOUTH OF THE SLOPE AT THE BATAN COAL MINE

NO PRETENTIOUS SURFACE EQUIPMENT HERE

that the Philippine fields have for so long been neglected. The government, too, is in great measure liable for much of the blame.

The Philippine government until lately denied foreign capital the right to do much development of natural resources, fearing that the rights of the natives would be usurped. The natives themselves not only lacked initiative, but what was worse they lacked the money to do things on a big scale. Furthermore, the Filipinos of the past generation knew as much about mining as a society matron knows about cooking; but now a liberal educational system inaugurated in the islands has turned out not a few native mining experts, and, as the Philippines have grown rich through world-war trade, there is no reason now why the extensive coal fields of the islands should not be rapidly and permanently developed. And it is gratifying to note that many of the promoters, in fact the majority, are Filipinos.

Coal is not used in the Philippines in households. The climate is tropical and such fuel is unsuited to the cooking methods employed, while of course house-heating apparatus is not used. But countless ships traversing world routes will call at Manila for coal once the Philippine mines get going in good shape. For many years the Japanese mines have held monopoly of all the coal business in that part of the world, notwithstanding the fact that the mines of China have been worked, after a fashion, for centuries. Both the United States and the Philippine governments will gain huge sums annually when sufficient coal is produced in the islands to meet the needs of the governments in operation there. The coal bill of the army transport service alone now reaches into the hundreds of thousands of dollars yearly.

IN A COMPETITIVE MARKET the impurities in steam coal are severely criticized by consumers. It is not difficult for a competent fireman to maintain steam under certain conditions when these impurities do not exceed 20 per cent. Coal which contains from 20 to 30 per cent. of impurities is frequently burned at the mines; however, as a rule it would be unprofitable to ship this product any distance. It should be burned close to the point of production. Transportation charges are a serious obstacle to the movement of coal containing 30 per cent. or more of impurities. Recently, all steam coal containing 20 per cent. or more of impurities was condemned by the Fuel Administration when it came under its observation.

Replies to Attack on Anthracite Coal Industry

S. D. Warriner, president of the Lehigh Coal & Navigation Co., one of the eight anthracite companies alleged by Senator Vardaman, of Mississippi, to constitute a monopoly of the anthracite business to the detriment of individual operators, on Mar. 4 issued a statement on points covered in the Vardaman statement. The Mississippi Senator, who retired from Congress on Mar. 4, made his address in the Senate as chairman of the Senate Manufactures Committee, which has been taking testimony on the anthracite situation, but which has not made any complete report. Said Mr. Warriner:

Senator Vardaman's remarks in no way bear out the testimony taken before the committee and the fact that the report was signed only by him clearly indicates that it does not represent the views of the other members of the committee. He speaks of a monopoly comprising eight companies. There was no evidence adduced to indicate any concerted action by these companies.

"Shortage of anthracite and high prices, due to monopolistic control," to use the Senator's reported language, are purely imaginary conditions. In the calendar year 1917 the total anthracite production was almost 100,000,000 net tons, the highest output ever reached, while for the calendar year 1918, with a decrease of 4000 employees and a most serious influenza epidemic, the output was within 200,000 net tons of the 1917 figure. The fact that output per employee per year rose from 548 tons in 1916 to 646 tons in 1917 and to 662 tons in 1918, should prove that neither employers nor employees spared any effort or labor to meet public needs.

Existing coal prices at the mines, and these are the only prices with which the operator has to do, have been set by Federal authority, and it is a matter of common knowledge, as well as a fact of public record, that the so-called railroad coal companies during the period of Fuel Administration control were selling coal at 75c. a ton less than the price obtained by the so-called individuals. Under the Lever act, prices fixed for coal were supposed to carry a fair margin for the producers, but Dr. Garfield himself, in his statement lifting all restrictions on anthracite Feb. 1, said that owing to general increases in the prices of labor and materials, the cost of mining anthracite had risen to such an extent that some producers, including so-called railroad interests, were mining at a "cost which resulted in many instances in a loss." Dr. Garfield added that, had he retained control, he would have found it necessary, on the basis of a Federal cost examination, to have raised maximum coal prices as much as 50c. a ton.

Anthracite, even on the basis of today's prices, has advanced less than half a hundred other commodities, in everyday use, when compared with the pre-war basis. Shoes, flour, textiles and many foodstuffs have doubled and even trebled in price, according to figures gathered and published by the Government, while the advance in anthracite has been far below those figures.

So far as freight rates and demurrage charges go, they are being applied by the United States Government through the Railroad Administration, and are matters with which the railroads, as such, have nothing to do, save enforce. Prior to the rule of the Railroad Administration, the established practices, including demurrage, storage facilities and interstate freight rates, were those fixed by the Interstate Commerce Commission.

It is perfectly true that there are coal interests which are affiliated with carrying companies, and it is correct that the Pennsylvania Constitution of 1874 forbids transportation companies to engage in mining. But it must be remembered that companies like the Lehigh Coal and Navigation Co., and others, hold their powers under charters granted long before the Constitution of 1874 was adopted and exercise specifically granted rights.

There is no policy of withholding land leases from independent operators. Senator Vardaman himself heard testimony in Pottsville on that point, where it was specifically stated by witnesses that they had been able to lease without difficulty or that, when a lease was refused, it was because another mine was working into the desired land.

Senator Vardaman, the printed reports indicate, did not mention the fact, also testified to in his presence, that the labor cost alone represents about 60 per cent. of the cost of anthracite on board at the mine, for labor is now receiving about four times as much as in 1901. This testimony is not only on the minutes of the committee, but similar testimony is available in the reports of the Fuel Administration engineers, made to Dr. Garfield.

The possibilities of reclaiming fuel from the culm banks, mentioned by Senator Vardaman, have been greatly overdrawn. In many of these banks there is much fuel, but it is almost entirely small sizes—pea coal and under. During the heavy war demand for coal domestic sizes were chiefly needed. To get this tonnage it was necessary to mine coal. The fact that with 176,552 employees in 1915 the hard coal mines produced 88,995,000 net tons, while with 150,245 employees in 1918 they produced 99,472,800 net tons, is a conclusive answer to any question involving the wisdom and practicability of the policy employed by the anthracite industry during the period of the war.

Failure of Sundry Civil Bill Works Out to Advantage of Fuel Administration

Failure of the sundry civil bill has left many of the Government bureaus in a state of uncertainty with regard to the appropriations which they will have for the next fiscal year. This is not the case with the Fuel Administration, however. The bill proposed to take away practically all of that organization's surplus. Failure of the measure, however, has left at the Fuel Administration's disposal some $750,000, which will provide for the closing of the Administration's affairs and

the compilation of its records without the exercise of parsimony. Of course, the bulk of that sum will be turned back into the Treasury voluntarily. The turn affairs have taken as a result of the failure of the bill is very gratifying to Fuel Administration officials, as the proposed action of Congress would have left them with insufficient funds to draw conclusions from their records, thereby making available to the industry statistics of great value.

Ohio Valley Operators Gain Decision in Important Traffic Case

In the important traffic case of the Ohio Valley Coal Operators' Association versus the Louisville & Nashville R.R., the Interstate Commerce Commission holds that the rates from mines in western Kentucky on the Louisville & Nashville Railroad to Cincinnati, Ohio, are and for the future will be unduly prejudicial to the extent they exceed or may exceed the rates from mines on the Louisville & Nashville R.R. in the Jellico-Middlesboro group in eastern Kentucky and Tennessee by more than 15c. per net ton.

The operators claim that Cincinnati is a natural market for western Kentucky coals and that the experience during the war has shown that it has given general satisfaction in that market. Their plea was for an adjustment of railroad rates so that their product might enter Cincinnati in normal times.

On the other hand, the railroad claims that the movement of coal in western Kentucky is much disjointed and requires an unusual amount of terminal and branch line service. The railroad also features the fact that the haul to Cincinnati must be accomplished against excessive grades. The railroad also declares that the character and grade of western Kentucky coal prevents its successful competition with other coals in the Cincinnati market. It was claimed that the western Kentucky coal was surrounded on all sides by superior coals mined in Indiana, Illinois, eastern Kentucky, Georgia and Alabama. In addition, it has to compete with water-borne coal from Pennsylvania and West Virginia. On these premises was based the conclusion by the railroad that the extensive use of western Kentucky coal during the war was due to the inability to secure the other coals. The commission held, however, that the weight of the evidence to that effect did not support the conclusion.

To Break Up Practice of Unfair Rejection of Coal Consignments

Plans are being considered by the National Coal Association, the American Wholesale Coal Association and the retailers' association to eliminate losses from the unfair rejection of consignments of coal. It is expected that the country will be divided into merchant centers, in which inspectors will be stationed to investigate the cause when shipments are rejected. When it is established that the consignee has unfairly declined to receive a shipment, it is the intention to have him placed on the cash list in the future. The operators and the wholesalers state that they are prepared to make determined efforts to break up the increasing tendency to turn back coal when changing conditions make it to the interest of the purchaser to do so.

Conflict of Opinion Regarding Percentage of Coal Lost in Transit

Conferences with the freight claim agents of the railroads have developed that the retailers are unwilling to allow any difference in weight of the car of coal at the time of its receipt by the railroad company and at the time of its delivery. The American Wholesale Coal Association is willing to disregard losses of 1 per cent. or less, but if the loss in transit is more than 1 per cent. it demands the full face of the claim. The Railroad Administration insists on a 1 per cent. variation in scale weights and 1 per cent. tolerance for evaporation. The National Coal Association has attempted to prove that absorption will balance evaporation, but has made no demands as to exact percentage of allowance.

An effort to harmonize the conflicting views will be made at another conference to be held the last week in March.

The secretary of the American Wholesale Coal Association is recommending that the wholesalers take the fight in their own hands by buying at the mine weight and selling at the delivered weight. The matter of recovery then would be entirely between the railroads and the wholesalers.

Important to Know Why Mines Suspend

Difficulty is being experienced by the statistical division of the Fuel Administration in obtaining information as to the closing of mines. As long as mines continue to operate, most of them are prompt in sending in returns; but when the operation is closed down no further report is forthcoming. It is essential in the compilation of the statistics, designed to help the industry, to know of each cessation of operation and the cause therefor.

Demurrage Rules Upheld on Lake Coal

Demurrage rules enforced in 1915 and 1916 by the Cincinnati, Hamilton & Dayton Ry. on Lake cargo coal have been upheld by the Interstate Commerce Commission. They had been attacked by the Cabin Creek Consolidated Coal Co. The Cabin Creek company, along with other shippers over the Cincinnati, Hamilton & Dayton, declared that five days is an insufficient free-time allowance to permit the accumulation of a cargo. The Commission does not agree and cites the fact that "the Pennsylvania company reports an average detention for all lake ports which it serves of 4.53 days in 1915 and 3.52 days in 1916. The average detention shown by the Toledo & Ohio Central R.R. at Toledo was 4.04 days in 1915 and 4.25 days in 1916; by the Hocking Valley Ry. at Toledo, 3.68 days in 1915 and 2.98 days in 1916; and by the Baltimore & Ohio R.R. at all ports, including the Cincinnati, Hamilton & Dayton R.R. at Toledo, 4.55 days in 1915 and 3.69 days in 1916."

A large number of gas masks, which originally were intended for army use, have come into the possession of concerns who are circularizing the mining industry and fire departments. In view of this fact the Bureau of Mines has issued a second warning against the use of army masks for industrial purposes.

EDITORIALS

Is the Business Man the Only Visionary?

THE convention of governors and mayors called by President Wilson passed a resolution thus worded: "We recommend to the states that they consider means of releasing natural resources from controllers who wilfully withhold such natural resources out of use for speculative profits or for visionary future development; thus contributing to unemployment." As this is addressed to states, evidently no reference is made to the Federal Government; but when reading about "controllers who wilfully withhold natural resources out of use for speculative profits or for visionary future development," one's mind naturally reverts to the Federal authorities who have placed such a high value on coal that it is not being purchased and operated. It is the bureaus of the Government which seek—for the Government, it is true—speculative profits and which have visions of excessively profitable future development. That being the case, why call the governors and mayors and why neglect to call the duly appointed constitutional authorities who have power over Federal matters—to wit, the members of Congress? But for certain unspecified but generally known reasons they have not been called.

The output of ten months in the anthracite fields is not enough to provide for domestic consumption in a year containing a normal number of cold days. As demand is closing the mines, it is quite possible that next winter there will be a coal shortage. The argument is: "Buy now" while anthracite is still down at that low-price level where a frugal, if not fair, Fuel Administration placed it. Later there will be a higher price and a difficulty in securing coal even at that figure. If a consumer will not spread his orders through the year he may expect to go short when the chilly days of 1920 *arrive.*

After the Manner of His Kind

AS WAS to be expected, the flood of destructive criticism indulged in by some of our law-givers at Washington has once more turned to the anthracite coal trade. Senator Vardaman, of Mississippi, chairman of the Manufacturers' Committee of the Senate, who recently conducted an investigation of the cost of producing anthracite, broke loose in the Senate last week with the usual stock phrases condemning the larger anthracite interests, with a few new twists evidently added for variety's sake.

It is hard to understand the motive of Mr. Vardaman, inasmuch as the statements which he made in the closing days of the last Congress were entirely at variance with the evidence as adduced before his committee. Inasmuch as his term of office expired with the expiration of this session of Congress, it may be his swan-song was attuned for home consumption with the hope of a successful come-back soon as an ardent supporter and tribune of the "rights of his dear peepul."

The statement that production had been curtailed during the war on account of the unwillingness of the big companies to develop virgin tracts is foolish on its very face. The facts are that in 1917 a record production of anthracite was made, and this again was almost equaled in 1918. With a shortage of about 30 per cent. in the labor force during both 1917 and 1918, it can be seen what a ridiculous figure the Senator has made of himself. The unfortunate part of the report is that it will be implicitly believed by the great bulk of the people, who have no desire to learn the true facts but are ever willing to believe that an advantage is being taken of them in the price of coal.

There can be no denying that evils at times creep into all big business institutions, and in this the coal trade is not alone. As we see it, one of the best things that could happen to the anthracite trade would be some arrangement whereby the independent operators in times of a flat market, as at the present time, might have the advantage of the storage yards maintained by the larger companies. To have made this statement a few years ago would have been to invite ridicule.

However, since the successful operation of the bituminous pools at seaboard under the auspices of the late Fuel Administration, it would seem entirely feasible for an arrangement of a similar kind to be made in regard to the anthracite storage yards. Such a plan would redound to the benefit of both large and small shippers. For one thing, it would stabilize the prices of coal and prevent its sale by individual shippers at less than the cost of production; further, it would release cars for the carriage of other merchandise and save the heavy demurrage charges which inevitably accumulate on shipments of coal that cannot find a market.

Probably the coal man will be most interested by that statement of Senator Vardaman which urged that the price of coal "be fixed by the Government at a rate which would guarantee a fair return to the mining companies and which would vouchsafe to the people of America an ample supply of anthracite at a reasonable price." That is just the problem the producers of anthracite are wrestling with at this moment. When all at interest can agree what is a "fair return" and a "reasonable price," the millennium will not be here exactly, but it will surely be just around the corner.

It would be pleasant, though futile, to endeavor to believe that in his attack on the practices and prices in the anthracite industry Senator Vardaman was free from a desire to play politics. It would be consoling if we could conclude that, after all, the only reason why his criticism was wide of the mark was because he, like the storied shoemaker who left his last to criticize details not pertaining to his craft, was trying to direct something of which he had no knowledge.

Unfortunately, when we try our hand at excusing, we remember that Vardaman comes from Mississippi, where cotton, which during the war was perhaps even

shorter in supply than coal, remained entirely unregulated and commanded a fabulous price. The senator, enraged at the coal situation, and loudly condemnatory of Government prices, was entirely unmoved by the more grievous cotton situation out of which his constituents were becoming wealthy.

He surely had every reason to believe that the cotton trust was unscrupulous. Had it not combined to raise the price of cotton? and had not the cotton planters in some years even threatened to burn some of the staple which had already been harvested? The senator hypocritically flagellates those who lost money and defends those who made it; he condemns those who have been selling at a loss and leaves without criticism those who profiteer; and he speaks still kindly to those who would burn what they have produced so as to raise prices unduly. Men like the Senator raise grave questions as to the soundness of democracy.

Third Liberty Bonds are yielding at present prices 4.85 per cent. They are the safest of investments, shrinking less than almost any others and sure eventually to sell at large profit. It is a patriotic and profitable duty to buy them and any other Liberty Bonds, new or old, and to keep them if possible when bought until they sell at a price above par. If a bond issue is not floated this spring there will be an excellent opportunity for the operator or wage earner who is able to make savings, to place those savings in old Liberty Bonds, where they will be safe and profitably invested and where they will perform a patriotic service.

Surely in This They Rob Us

SENATOR VARDAMAN, by much patience, has discovered that the anthracite-producing companies are few in number and large. True enough. But what of it? Their prices satisfied the Fuel Administration, and now many of them are selling coal at less than cost. Those who would have everything sold at or below cost should be pleased that there are companies, however large, which will be so accommodating, though surely all of us will realize that the condition cannot last and would not be for the good of anyone if it did.

To work without profit is to put nothing aside, and to put nothing aside is the height of infrugality. To live beyond one's income, as many anthracite companies are doing, is even more to be reprobated. If every person and company expended more than they received then the nation would be impoverished. Surely when the anthracite coal companies sell coal at a loss they rob us, for they are a part of us; and if they waste their resources they reduce the wealth of the nation.

Let us never believe, as some do, that unprofitable industry is fruitful for the nation. Those uncharitable people who go out into their neighbor's fields and wish them a poor crop and a wet harvest are wishing themselves bad luck. When they invite a malediction of Providence on the farmer they are banning themselves as well as the toiler in the furrows. So also do we seek for ourselves an ill when we desire the manufacturer to put out his goods or the operator to sell his coal at a loss, for a loss to one is a loss to all.

But anthracite coal, we say, is selling at a high price. That is true, as compared with former costs. As compared with other articles, as compared with wages and cost of materials, as compared with the average power of purchase and as compared with the price that will have to be paid if the industry is to continue to supply our needs, anthracite coal is not expensive today but unduly cheap, Senator Vardaman to the contrary.

Let every state beware of becoming only a raw-material state. Some states with great opportunities finish nothing, yet begin everything. They ship the raw materials out and ship manufactured articles in, whereas they could fashion the materials and assemble the fashioned parts in their own back yards. West Virginia is an example of a state which performs only the simplest of operations, making little coke, no near-coke, only a small amount of electric power, and no byproducts. It should use more of its coal within its own borders and save the wastes and costs of transportation. Having no iron deposits it cannot, of course, be as self-contained as Pennsylvania could be but is not.

Is the Pyrite in Coal Intrinsic?

SOME recognition is being given at last to the idea that the pyrite in coal is organic and intrinsic. In an article appearing in "The Resources of Tennessee," entitled "Coal Pyrite Resources of Tennessee," by E. A. Holbrook and Wilbur A. Nelson, the authors say: "Because coal in a mine contains pyrite balls, or bands, does not mean that the coal from this mine is high in sulphur or inferior in quality; for often the contrary is true, that the sulphur, having concentrated into definite balls, or bands, leaves the coal comparatively free of sulphur."

It is likely that the sulphur in coal will eventually be found to be but rarely of an outside origin, though it is not safe to assume at the present stage that this is true of all of it. The "sulphur balls," as they are called, may well be considered, as to the authors just quoted allege, signs of desulphurization of the coal. It will be interesting to learn some day what wonderful plant in the ancient days secreted so much sulphur. It must have been as full of odor as the leek or the onion —and as greatly tear-provoking. Some of the coal forests must have been thickly bespread with it. True sulphur appears in concentration, the volatile matters having been removed; but with all allowances and every imagination, how can we explain beds which carry 6 per cent. of sulphur, and even more, in the general run of the coal?

Quite wisely the Government has reopened the opportunity for converting the first and second series of Liberty Bonds into bonds which pay not 3½ or 4 per cent., but 4¼ per cent. This is the conversion privilege which was kept open till Nov. 9 of last year and then closed indefinitely. Now it is opened, the operator should induce his men to avert themselves of the renewed opportunity for exchange. Second, Fours have been selling at a lower figure than the Second Converted Fours, and conversion is the best practice for every one including the mine worker. The most profitable course with First 3½ Liberty Bonds is to sell them on the market and buy a 4¼ issue, putting the difference in the bank.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Mine workers in Illinois are somewhat generally demanding the shorter day, being led in that demand by the president of their branch of the union, Frank Farrington. They argue that shorter hours would keep every one working an equal length of time throughout the industry regardless of the quality of the coal worked. They want the worst coal of Illinois, Iowa and Indiana to be mined as steadily as the best in Pennsylvania and West Virginia. The consumer might well not be pleased with such an outcome of union activity, but that is not the worst objection to Mr. Farrington's proposal.

Should we place the industry on a six-hour basis, if only for a few months, the mine workers would be disposed to try to keep it there. When there would again be a big demand for coal it would be impossible to secure it working on a six-hour basis. As a result there would be another coal shortage and more working men would flock to the industry, in fact they might come before that auspicuous hour. The last state of the industry would then be worse than the first. The flood of men would seem to make it necessary to make a four-hour day when business became slack. More men would enter the mines, and at the next business flood, still more men would be engaged. A three-hour or a two-hour day would be proposed and so on indefinitely.

We should thus have an infinite series of decreasing terms ending in zero. If the Farrington cure for slackness is to be taken at every decline in business, a long-time invigorator should be swallowed whenever business briskened. The reason why the mines are flooded with men is because the regular mine workers did not meet the demand when it came. This, of course, they cannot deny. They will say, however, and say with truth, that a very important reason for not meeting that demand was the loss of the working force due to the absence of men in the Army and munition works.

Farrington has more excuse than the British advocates of shorter time. In Great Britain there is an acute shortage of coal and of working places. No more than a certain number of men can be employed, but each man should get out his utmost in order to meet the emergency. The short day will not serve in Great Britain even during slackness of employment, whereas it might conceivably do little harm here if the mine worker realized it as only a temporary expedient. Everyone who knows the mine worker well knows he would not so regard it but would want to keep his six-hour day and twelve-hour pay indefinitely.

Want Larger Accident Compensation

The presidents of all the five districts that have been established by the United Workers of America in Pennsylvania recently held a meeting with Harry A. Mackey, chairman of the compensation board, and Francis H. Bohlen, the counsel for the board, and discussed with them amendments to the compensation law. The revision of the law thus proposed would raise the compensation, reduce the waiting period after which compensation is paid, provide compensation for disfigurement, eliminate the section providing for the proving of dependency and insert a specified period during which compensation shall be paid for partial disability and for specific injuries.

The increase in compensation has nothing to do with the increased cost of living consequent on the war, for in Pennsylvania the compensation is dependent solely on the wage earned and is not limited to a certain amount, as in West Virginia. The compensation has therefore increased with the advance in wages. Even before the war the mine workers of Pennsylvania argued that the compensation should be larger. At earlier conferences the labor representatives sought an increase that would bring the compensation up to 50 per cent. or 60 per cent. or even 66⅔ per cent. of the weekly wages. The demand is now for 70 per cent. The compensation board approves of an increase, but has not set a definite figure on the compensation to be paid.

The executive boards of the five Pennsylvania districts of the United Mine Workers of America have met and have ratified the work of the presidents, and these presidents on Feb. 20 called on Governor W. C. Sproul and Attorney General Schaeffer and discussed these proposed amendments. Governor Sproul declared that he would favor any changes recommended by members of the compensation board, or agreed on between representatives of organized labor and members of the compensation board.

Representative David Fowler, of Scranton, who is a national organizer of the mine workers' union, has been selected as the man to introduce to the legislature the bill containing the proposed amendments. What the compensation should be is not easy to determine. What is clear is that the compensation should not be made so high as to make any numerous body of men prefer idling under compensation to working without it.

An amendment to the workmen's compensation act was introduced in the House on Feb. 20, by Mr. Deitrich, Allegheny County, which provides that where injury arises from the failure of the employer to obey safety requirements no consideration shall be allowed to affect the liability of the employer. The injured person or his representative or his dependents may either claim compensation or institute civil proceedings.

Militia Gone, Must Have State Police

In West Virginia, the mine workers and particularly their leaders bitterly oppose the proposed police-patrol or indeed any other constabulary bill, although it is generally conceded that the state must have some form of police protection now that there is no longer any national guard available. The Governor will include in his call for a special session the question of state police legislation and it is generally believed that the legislature will enact laws providing for a state police despite the opposition of the mine workers. The Governor and others have pointed out to those opposing the legislation that the quickest way to eliminate the mine guards often employed by individual corporations is through an organized form of police supervision vested in the state. The miners do not seem to be able to see this, however.

District President Implicated in Affray

On the charge of having been implicated in a shooting affray at Glen White in November, 1917, J. R. Gilmore, president of District 29, together with Lawrence Dwyer, international board member for that district, and district board members Stafford and Clendenin, of the United Mine Workers, were placed under arrest at Beckley, W. Va., on Feb. 18, a warrant having been sworn out by Geo. W. Williams. Twelve other warrants were also sworn out against certain mine workers charged with being implicated in the shooting. This is alleged to have occurred during a strike and just at that time of the day when nonunion mine workers were leaving the mine. Refusing to require a bond for $3000 the trial justice released the men under a $1000 bond. No one was injured by the shots fired.

Farrington Plans Shorter Day and Week

Illinois miners are getting ready to demand a six-hour day and a five-day week. This is indicated in a "keynote" letter issued by Frank Farrington, president of the United Mine Workers of Illinois, sent out under date of Feb. 21, in which he frankly says: "Our goal should be a six-hour day, five days per week, for all the miners in the United States, with no double-shift on the coal allowed except as necessity may require. Development for increased tonnage should not be considered a necessity. Every atom of strength of the United Mine Workers of America should be employed to accomplish that end and then we should strive to have the Government prevent the opening of new operations, except as new operations may be needed to supply the demand for coal. If this is done every mine worker will then have a chance to earn a decent living and the matter of equalizing and adjusting wages will be easy of accomplishment, and until it is done unemployment and consequent want and suffering will ever be present among the mine workers of the United States."

Leading up to the demand, Farrington says: "The great evil of mining is unemployment and the absence of uniformity in wages paid as between competing districts. Even now hundreds of thousands of mine workers are feeling the pinch of slackened work, and, as a result, hunger and want are stalking in their midst and threatening their future. True, it is hoped that industrial activity, temporarily suspended, will soon resume a normal status and that the surplus of coal now above ground will soon be consumed and the situation thus be relieved, but even that will not cure the evil from which mine workers suffer and the reason it will not is because the mining industry is fully 50 per cent. overdeveloped, which means that there are fully 50 per cent. more men employed in the mines of the United States than are necessary to supply the normal demand for coal.

"So long as that condition exists unemployment will exist and work will be best where wages are lowest, as the demand for coal will be largely supplied from districts where it can be purchased the cheapest, with the inevitable result that wages in districts having higher wage scales will always be threatened with lack of employment. Therefore we must create a condition whereby districts having low wages will have no advantage over districts having high wages when it comes to the number of days worked. Or in other words we must create a condition whereby a low wage scale will be of no competitive value to an operator when it comes to getting a market for his coal, and the only way that can be done is to create a condition that will make it necessary to work practically all the mines full running time in order to supply the demand for coal, and the only way that can be done is by reducing the hours of labor, and our salvation is in our ability to do so."

Compensation Revision in Missouri

The Workmen's Compensation Committee of the Missouri Legislature, after futile efforts to agree upon a substitute bill which would reconcile differences between employers and employees, has voted to report favorably, with amendments, the bill favored by the employees. As this bill provides for monopolistic State insurance, to which the employers are strongly opposed, and also for other reasons, the employers will make every effort to defeat the bill and are confident that they can do so in the Senate if not in the House. The insurance companies also will fight it.

The principal amendments agreed upon by the committee provide: A waiting period of five days, for which compensation shall be given if the incapacity extends over three weeks and a maximum compensation of $30 a week. The amendments also arrange that the workmen's compensation commission shall decide whether compensation shall be in a lump sum or shall be spread over a period of weeks. It prevents an injured employee from receiving more as compensation than he would have received as wage for an equal period of disability. The salaries of members of the commission are reduced from $7000 to $5000 a year and a fine and imprisonment is provided for any person who is found guilty of making false statements about the condition of the insurance fund.

Block-Coal Company Settles Strike

When the contract was made in the block-coal district of Indiana, of which Brazil is the principal town, a differential of 6c. per ton was provided where the top coal is left. The contract provides that the men receive 67c. per ton for the loading of the coal and that the company drill the shotholes. The men of the Powers Collieries Co. at Mine No. 2, recently, contending that the drilling force of the company was inadequate and too slow in drilling the holes, went on strike. The company settled with the men by providing that they drill their own holes and in return receive 2c. more for loading, or 69c. per ton. The roof is bad and the top coal has to be left to support it.

Want Compensation Act Amended

The coal miners of the Crowsnest Pass District, through the medium of Gladstone Local Union, No. 2314 United Mine Workers of America, are petitioning for amendments to the Workmen's Compensation Act of British Columbia. They declare for a variety of reasons that changes should be made providing for the board being represented in the Crow's Nest District by permanent representatives; for an increase of 100 per cent. in the compensation allowed for dependents; for a clause permitting workmen to take proceedings at common law in case of serious injuries and where it is suspected that the accident was caused by negligence; and for an amendment that will allow appeals from the decision of the Workmen's Compensation Board to the Court of Appeal.

Nova Scotians Don't Stop to Eat

On Feb. 24, the Amalgamated Mine Workers of Nova Scotia adopted an agreement which reduces the working day from 12 hours and 10 hours to 8 hours. The "datal" men who are paid by the day, and not by the hour, will get the full day wage without any reduction, but the "hourly paid" men will receive no change in the hour rate.

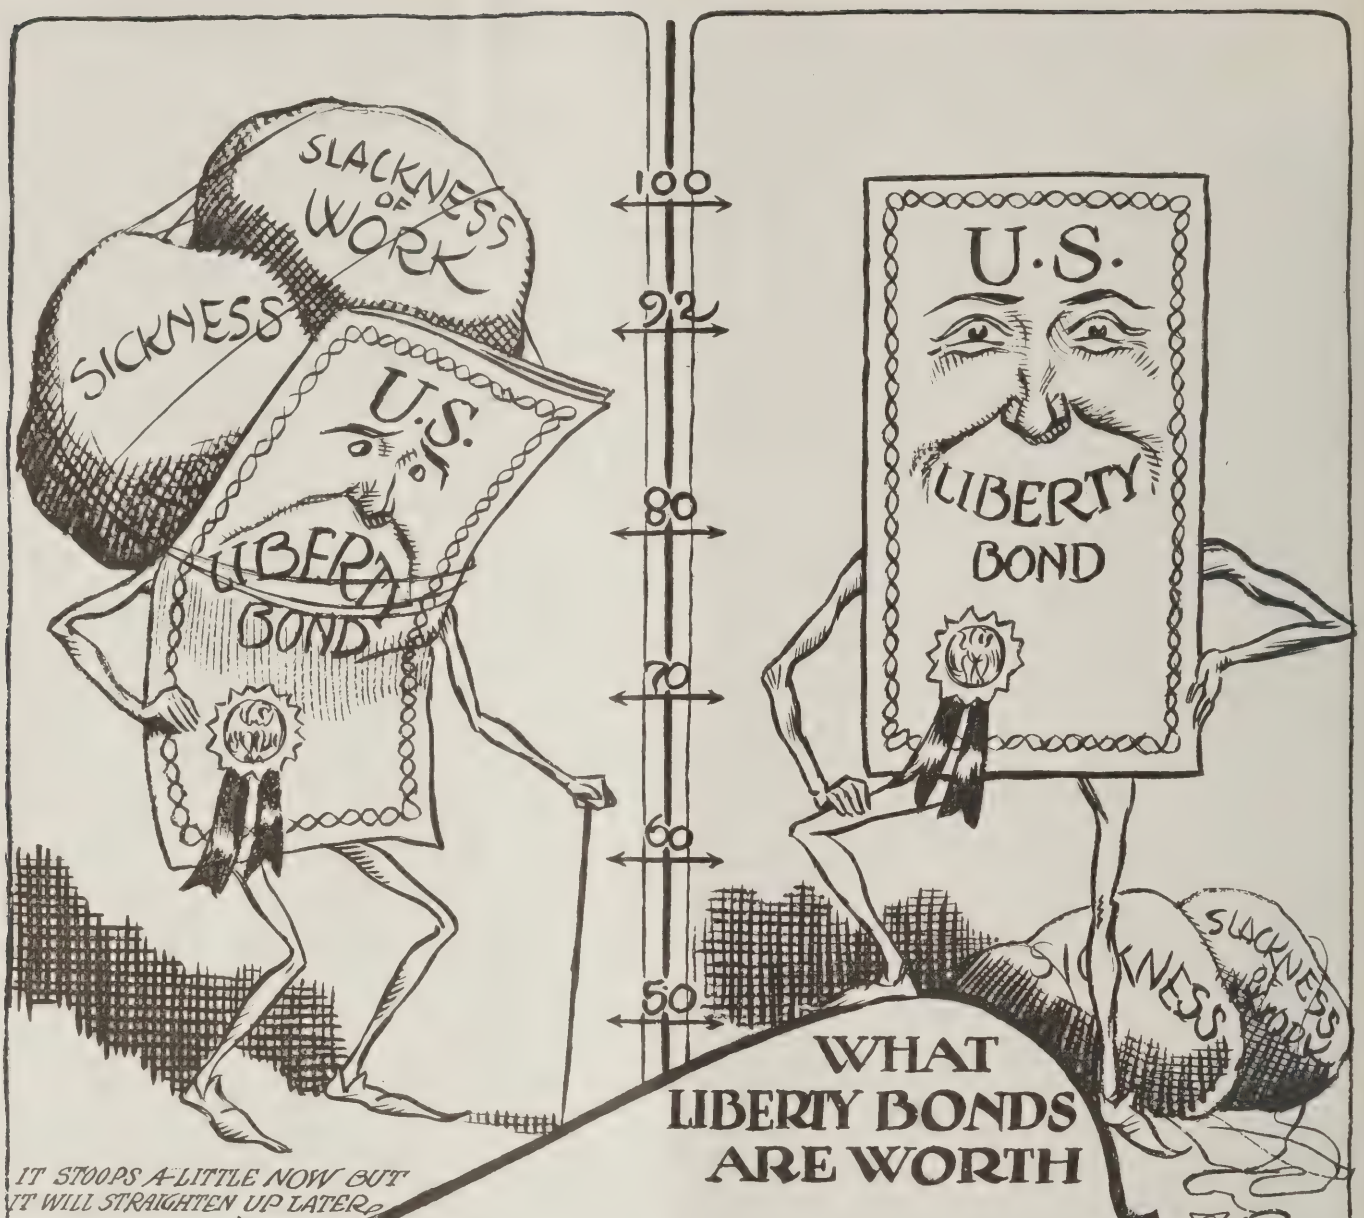
The men are well pleased that the operators met with them to discuss terms and are also much gratified that they have secured the eight-hour day. The proposal of the operators which the mine workers have accepted is as follows:

"The operators have carefully considered the proposal of their employees for an eight-hour day, and being most desirous so far as possible to meet their wishes, would submit the following offer:

"1. The collieries will commence to hoist coal at 7 a.m., at which time all the men must be in the mine.

"2. The day's work will cease at 3 o'clock, when all arrangements will be available for conveying the men to the surface.

"3. The surface men around the bankhead and screens associated with the handling of coal are to be on duty between the hours of 7 a.m. and 3 p.m. and for a short time after, if necessary, for the purpose of attending to such duties as will facilitate their own work, such time not to exceed a half hour.



"4. The working day of other surface labor around the collieries to be from 7 a.m. to 4 p.m., with half an hour for dinner.

"5. Where continuous attendance is required, the shifts will be eight hours instead of twelve, both surface and underground at the same pay.

"6. The conditions peculiar to certain localities will be adjusted locally.

"7. The agreement will become effective Mar. 15, 16 or 17, according to the date on which the pay rolls are made.

"Clause 1 means that the mine shall run continuously between the hours named, without any stop whatever."

WHAT LIBERTY BONDS ARE WORTH

Slack work and sickness are making some patriotic men sell the Liberty Bonds they worked so hard to get. No one should sell a bond, if by a little skimping he could keep it. All payments still due on bonds should be made as soon as possible.

But if bonds must be sold, don't sacrifice them for little or nothing. Any bona fide broker will give you at least $92 for a $100 bond and more than that for the 3½ per cent. bond, as first issued.

Liberty Bonds have fallen in value because so many are being sold and no effort has been made to induce any one to buy them from those who want to sell. Patriotic people who will buy new bonds will not purchase old ones, though they cost less and are just as good.

Unless in Trouble Keep Your Liberty Bonds.

DISCUSSION BY READERS

Cost Reduced in Machine Mining

Letter No. 1—Speaking of increasing the output of mines and reducing the cost of their operation, referred to by one writer in *Coal Age*, let me say that, in my short experience as mine foreman, I have been able to greatly increase the output of our mine and at the same time show a lesser cost since installing two Sullivan coal cutters. The performance of this machine has exceeded my best expectations.

The machine we have installed is handled easily and cuts well down to the bottom, leaving from 4½ to 5 in. of bottom coal. I will not attempt to describe minutely the special bit used in this machine, which is one of its valuable features and which, I believe, enables it to forge ahead without bucking, even when operating on a soft bottom; and when a horseback is struck, the machine never stops.

An important point in regard to keeping the cost low is that no machine boss is required to look after the machines and keep them in good condition. So far, our machinemen repair their own machines very easily. Although I have worked in mines where other types of machines have been used, I have never known them to perform the same work with as little trouble.

Our cutters can easily cut from 15 to 20 places in a single night and are not as tired as if they had mined and loaded five cars of coal in that time. I cite this experience hoping that it may prove of value to other young foremen who are making every effort to reduce operating costs in their mines. I believe that the mining of coal by machines, where conditions will permit of their use, is the solution of the cost problem.

Oliphant Furnace, Penn. JOHN H. WILEY.

Correct Accounting

Letter No. 1—Referring to the question of an accountant, which appeared in *Coal Age*, Jan. 30, p. 248, and the reply given by the editor, on the same page, allow me to say that the distinction made between the capital invested in any permanent enterprise and the working expenditures of the business affords some field for discussion among accountants. However, in the case of coal mining and other similarly wasteful enterprises, experience teaches that the field for such a discussion is extremely limited.

Kindly permit me to express the opinion that, after a mine has been developed and equipped to its normal and regular output of capacity, the cost of any additional equipment that may be required to maintain the output, under the increasing length of haul, due to the advance of the working faces in the extraction of the mineral, should be charged as ordinary and necessary expense of operating the mine.

Likewise, also, the cost of additional copper wire, piping, and other conductors for the transmission of power into the extended workings are chargeable to the same account, forming, as they do, a part of the necessary working expenses of the mine. In the same manner, additional mules, mine cars, locomotives, mining machines, pumps, and other appliances supplied to replace those worn out and discarded in the service of the mine, form a part of the legitimate working expenses and, as such, should be charged to the expense account.

REGARDS EQUIPMENT RENEWALS AS EXPENSE

My reason for this opinion, which appears to be at variance with that of the editorial reply to this inquiry, is as follows: The cost of such items as I have named is a constantly recurring expense in the operation of a coal mine and may be regarded as constituting a practically constant factor in the cost of production per ton of coal mined, from year to year. It makes no appreciable difference in the final result of the business whether the cost of these items is charged to operating expense or capitalized and entered as additional equipment, which must then be offset by deductions representing a certain depreciation that would have to be determined, each year, during the life of the mine.

My opinion is that, as a practical matter, it is better to dispose of such costs by direct charge to operating expense, rather than to introduce vexatious refinements of accounting, which would be necessary if such costs were to be capitalized and depreciated.

THOMAS T. BREWSTER, Gen. Mgr.,
St. Louis, Mo. Mount Olive & Staunton Coal Co.

[Regarding the suggestion of this correspondent, it would be interesting to know how the equipment ledger of a large operation is to be kept in a manner that will show the correct valuation of the equipment on hand and in use in the mine, at the close of any fiscal year, unless new purchases of equipment are regularly entered as such when taken into the mine.

It is readily granted that a new pump or other machine may be purchased to replace one that is worn out and discarded. At the same time, the new machine may be an improved type, which it generally is, and have a greater value than the machine it replaces. Again, the change in market values varies widely, from time to time, depending on relative supply and demand, quality of material, cost of labor, style and degree of workmanship, etc., etc.

It is quite clear that a correct method of accounting can only be maintained when the equipment and other accounts are properly charged and credited with each transaction as it occurs. The best business practice requires that a complete inventory of equipment and material be made at the close of each fiscal year, and a suitable valuation placed on the several items of the account. Only in this manner is it possible to show

the present condition and value of an operation, which would have to be done should a change in ownership be contemplated.

Coal Age will be glad to learn the opinions of other managers, superintendents, and accountants.—Editor.]

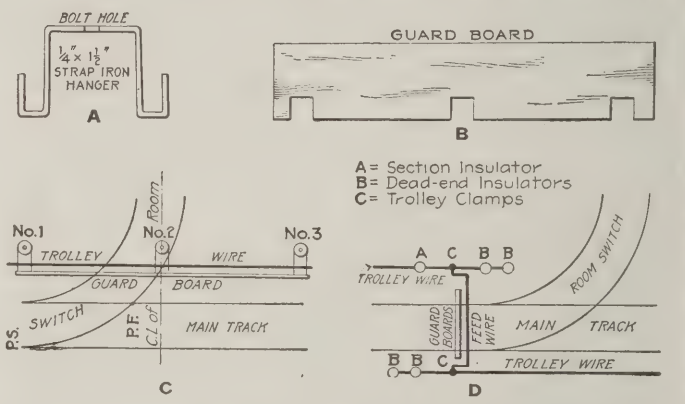
Safeguards in Trolley Haulage

Letter No. 1—The inquiry of "Motorman," *Coal Age*, Jan. 9, p. 71, is an interesting one, particularly to men who realize that an electric installation in a coal mine is an important factor in its operation. As stated in the answer to this inquiry, the installation of an electric-haulage system should be made by a practical and competent mining electrician, whose contact with various conditions that exist in coal mining will enable him to provide against any contingency that is liable to arise.

When a management, wishing to produce coal at a minimum cost, decides to electrify its mines it is important to consider carefully the necessary electrical appliances that will make the proposition a paying investment. Faulty design and incompetent installation mean either extensive changes, later, or increased operating and upkeep expenses. Knowing this, the competent electrician makes a careful survey of the situation, which enables him to design the installation so as to meet the requirements in the simplest and most economical manner.

Essential Factors in Electric Haulage

The efficiency of electric mine haulage depends upon two important factors; namely, the overhead circuit and the track-return circuit. A first-class, bonded-return circuit always bears a definite relation to the tonnage of coal hauled. Therefore, one of the safeguards of economical haulage is to provide against the serious loss that is sure to follow the poor bonding of the rails. In fact, the return circuit of an electric haulage should be tested, from time to time, if the highest efficiency of the system is to be maintained. In all permanent work the "compressed-terminal bond" should be employed. The channel-pin method of bonding should only be used for temporary work.



In the installation of the overhead circuit, every precaution should be taken, both outside and inside of the mine, to minimize fire hazard; reduce the cost of upkeep; provide economical operation; and to safeguard employees by eliminating, as far as possible, the danger of contact with live wires. The efficient and economical operation of electric locomotives, cutting machines, pumps, fans, etc., depends on the selection of motor equipment, the capacity of which must be sufficient to perform the required work without unnecessary heating, and yet avoid operating the motor too far under its economical load. Both feeder and return circuits must provide ample conductivity to prevent excessive drop in voltage.

All trolley-wire hangers must be installed true with the track and practically at the same height above the rails, in order to avoid the danger of a trolley pole jumping off the wire, and excessive arcing at the trolley wheel. The center of each hanger should be from 6 to 8 in. outside of the rail, unless otherwise modified by the state mining law or the size and type of locomotive to be used.

The severest mechanical stress placed upon hangers is that encountered on curves, where a sufficient number of hangers and trolley clamps should be installed to prevent them from being bent out of line. No fixed rule can be given for spacing the hangers apart, as this will depend chiefly on the degree of curve. However, in common mining practice, a distance of 8 or 10 ft. has generally given satisfactory results.

On a straight track, some difference of opinion exists as to the proper distance apart of installing hangers, in the use of 250 and 550 volts. But, hangers should never be spaced so far apart as to cause an undue sag in the trolley wire. Because of varying conditions in different mines, this is the only safe rule that can be given. My own practice has been to adopt a distance of 18 ft., center to center of hangers, for 0000-trolley wire, on straight tracks, and from 8 to 10 ft. on ordinary mine curves.

In order to safeguard employees from contact with the trolley wire, guard boards must be installed at all points where men and animals pass under the wire. For

ELECTRIC-HAULAGE INSTALLATION IN MINES

the support of the guard boards, the strap iron hanger, shown at (*a*) in the accompanying figure, is the simplest device to employ. This is made to be supported by the regular trolley-wire hanger, without drilling any extra holes, the same bolt that supports the latter also passes through a hole in the strap-iron hanger.

The form of the guard boards used to protect the trolley wire is shown at (*b*) in the figure. Three hangers should be installed at each roomneck where the trolley wire crosses the mouth of the room. These hangers support two guard boards, 1 x 6 in. and of suitable length to protect the wire. As indicated in the figure, the boards are made with three notches to fit the three hangers.

At (*c*) in the figure, is shown the best location of the three hangers, No. 1 being opposite the point of switch, No. 2 on the center line of the room, and No. 3 beyond the point of frog. When the expansion bolt has been driven into place in the roof the strap-iron hanger is held up against the roof while the trolley-wire hanger is screwed on the expansion bolt, thus holding the strap hanger firmly against the roof. Weather boarding is quite generally used for guard boards, since it is pliable and easily adapted to any conditions.

An important matter, in safeguarding the efficiency in trolley haulage, is the proper location of the trolley frog. It is a difficult matter to give a fixed rule here also, because of the difference in degree of curves em-

ployed and the spread of the trolley frog. I have generally found good satisfaction in locating the trolley frog at a point where the lead rail of the switch has deflected 6 in. from the straight rail on the entry, this measurement being taken between the outside edges of the two rails.

While this rule has given good satisfaction in my own practice, it is well to remember that the test of the proper location of a trolley frog is the freedom with which the trolley pole operates over the frog, without jumping, both when the motor is running over the switch and on the main line. If the trolley jumps off the wire when crossing the frog, the location of the latter should be changed. The jumping of the trolley pole means delay and loss in efficiency.

Hanging Trolley Wire on Room Headings

Where it is desired to install a trolley wire so as to avoid its crossing the roomnecks, it is necessary to transfer the wire to the opposite side of the road, as shown at (*d*) in the figure. A section insulator (*A*) should be installed outside of the first room, where the transfer of the trolley wire takes place. A feeder wire of equal carrying capacity is then used to carry the current across the entry to the opposite side of the track. This feed wire is soldered to two trolley clamps (*CC*) attached to the trolley wires. As shown in the figure, the feed wire is protected by guard boards.

I have only seen one installation of this kind in use and, owing to its inconvenience, it was later abandoned. The locomotive must be provided with two trolley poles and there is much delay in the use of the system. The usual practice, in some of the largest mines, is to install the trolley wire on the room side of the entry. This has given good satisfaction and, practically, no accidents have occurred when the installation has been properly made. In any case, a section insulator located at the mouth of the heading enables the current to be cut off, if desired, when the locomotive is out of the heading.

T. C. Hughes,
Windber, Penn. Mine Electrician.

Letter No. 2—Referring to the inquiry of "Motorman," *Coal Age*, Jan. 9, p. 71, asking for the simplest and best method of protecting the trolley wire in mine haulage, kindly permit me to submit for his consideration a scheme that I have found very practical and which I believe is the simplest device that can be used for that purpose.

My plan is to have the mine blacksmith take a piece of strap iron 1½ x ¼ in., say 20 in. in length, and bend it in the shape shown in my rough sketch. [See Letter No. 1, Fig. (*a*)]. A hole is then made in the center of the upper bend, to fit the bolt that supports the bell or other form of trolley hanger.

The use of this device is clear without further explanation than to say that two or more of these supports having been placed in position and made secure on consecutive hangers of the trolley wire, weatherboards or slats, 4 or 5 in. wide and cut to the proper length, are placed in the supports, a board on each side of the trolley wire.

In my mining practice, this arrangement has been found to give good satisfaction; it is cheap, quickly made and put in place. It has been my custom to have the blacksmith make a number of these supports, which are kept on hand ready for use as needed. The dimensions given in my sketch are only suggestive, as the supports described can be bent so as to fit any hanger in use in the mine, and this should be done to insure the best satisfaction.

Mine Mechanic.
Rosebud, W. Va.

Mule Power in Mine Haulage

Letter No. 1—Replying to H. R. S., who asked, in *Coal Age*, Feb. 6, p. 293, "What is a fair estimate of the work that a good average mine mule or horse will perform when working under average conditions, in a level seam," allow me to give a little of my own experience in respect to mule haulage.

From the records of a few years ago, now before me, a mule hauled 116 wagons and traveled 14 miles; another hauled 94 wagons, traveling 11 miles; and yet another, 27 wagons, traveling 17 miles. These records refer to uneven grades and a 10-hour shift.

My opinion is that, on well-drained roads, in a level seam, the average mule or horse will travel 15 miles, in a 10-hour shift, with one hour to eat and rest, which means 9 hours of actual work. When gathering cars with mules, the longest distance hauled should not exceed 1000 ft., and the shortest distance may be, say, 200 ft., making the mean average one-way haul 600 ft., or 1200 ft. for the round trip. Then, if a mule will travel 15 miles in a single shift, he will make $15 \times 5280 \div 1200 = 66$ trips.

On a level track the mule will haul two 2-ton wagons, or 4 tons of coal, each trip. Expressed in ton-mile hours, therefore, the work of an average mine mule would be $4 \times 15 \div 9 = 6\frac{2}{3}$ ton-mile hours, which is practically the estimate given in the reply to this inquiry by the editor.

The record of the faithful mine mule is one that cannot be idly set aside, where the conditions regarding length of haul and grade are favorable, it is an inducement to keep the mule in harness rather than to harness Niagara.

R. W. Lightburn.
Perryopolis, Penn.

Drawing Pillars in Machine Mining

Letter No. 9—Referring to the inquiry on this subject, *Coal Age*, Jan. 2, p. 32, it is unfortunate that the writer does not give the thickness of the pillars between the rooms, as this is an important factor in the work of drawing pillars with machines. He states that the rooms are 27 ft. wide, which would seem to present the possibility of danger of the roof pressure swinging over onto the pillars and starting a squeeze, which would not only endanger the pillar work but cause a large loss of coal besides. It is possible, however, that the pillars are of sufficient thickness to resist this action.

The seam mentioned here being from 4½ to 5 ft. in thickness and the depth of cover 200 ft., one must be guided, in deciding on the best method of drawing back the pillars with machines, by considering the thickness of the sandrock roof and the nature of the material immediately above it. If this sandrock is, say only 2 ft. in thickness and overlaid with several feet of soft

shale, such a roof can be easily fractured, with much less resistance in the pillars, than if the sandrock above the coal was from 4 to 6 ft. in thickness or even more. It is clear, therefore, that this is an important consideration and one that must be taken into account in deciding the method to be employed in extracting the pillars

If the problem was mine for solution, I would start and make a 60-ft. cut through the rib in the innermost room, following this with a 40-ft. cut through the next rib outby, a 30-ft. cut through the next rib and 20-ft. cuts in each of the three following ribs, making six ribs cut through in all. Assuming the rooms are driven on 40-ft. centers, there would thus be made an open length covering six ribs and seven rooms, which would give a total length of 267 feet.

The next cuts are made in each rib, after leaving an 8-ft. stump for the protection of the men and the machine, and are as follows: A 30-ft. cut in the innermost rib, a 25-ft. cut in the next rib outby, a 20-ft. cut in the next, and 15-ft. cuts in each of the three last ribs. Each of these cuts is protected, as stated, with an 8-ft. stump that is taken out later.

Watching for the First Break to Determine the Angle of Fracture

In my estimation, by the time this extraction is completed, the indications will determine the particular angle of the fracture line that will give the best results. However, let me say that when mining under a strong sandrock roof and with the expectation of drawing back the pillars with machines, the rooms should be driven with a less width, unless the pillars are made equally wide.

The angle of fracture, or the angle that the line of fracture makes with the heading, should not exceed 25 or 30 deg., so as to throw the thrust on the ends of the pillars and not cause the weight to ride over onto them, a distance half-way down the room. It may be wise to still further reduce the angle of fracture to, say 15 deg., under a 40-ft. sandrock cover, or even make the fracture line parallel to the heading, by altering the width of the cuts in the ribs, previously given. I would even suggest using three rows of chocks for support behind the retreating pillars, instead of leaving the 8-ft. stump previously mentioned. These chocks should be moved forward, one row at a time, as the work on the pillars progresses. R. W. Lightburn.

Perryopolis, Penn.

Efficiency of Mine Officials

Letter No. 2—The letter of William Gorman, *Coal Age*, Jan. 16, p. 159, interested me much, drawing attention as it did to the need of greater efficiency on the part of mine superintendents. I agree with the suggestion that there has been too much undeserved criticism of mine foremen, while little has been said in respect to superintendents; but, apparently, even Mr. Gorman cannot resist the opportunity of giving the much abused mine foreman a jab, in his letter.

Let me say, here, that if any good is to come out of a discussion, we must stick close to the point. To my mind, a good superintendent shows his ability by the foremen he employs. Having but one pair of eyes, the superintendent cannot see everything that goes on in the mine. He must rely, to a large extent, on his underofficials; if they are the right kind of men he can trust them to see that his orders are carried out.

In the mining of coal, there is no room for a superintendent who continually wears a white collar and whose knowledge of things in and around the mine is only what has been told him by the mine foreman or the fireboss. There are many things, of course, to be looked after on the surface; but more than all else, in importance, is the development of the mine and the daily operations underground, on the success of which the profits of the mine depend. No one, today, considers a mine superintendent efficient who visits the mine on rare occasions only.

When a Superintendent's Visits to the Mine Do More Harm Than Good

Speaking of superintendents, there is one class of these officials that do more harm than good by going into the mine. The mine foreman would fare far better if they stayed out altogether. They will slip into a mine and, unknown to the foreman, visit the working places and make inquiries of the men regarding the foreman. Such a practice can only have a bad effect on the men, as it tends to decrease the prestige of the foreman and destroy his authority in the mine.

In common with other superintendents, I like to go into the mines alone, visit the working places and chat with the men; but if they start to talking about their claims for yardage, or lost cars, or other allowances that should be made them, I refer them promptly to the foreman, telling them he is the man to see. But it often happens that I mention the matter to the foreman myself, later, for the purpose of informing him of the disposition of his men.

However, when a superintendent expects to be in the mine later in the day, I think it is only right for him to mention the matter to the foreman in the morning. It would have a tendency to disarm any lurking suspicion of his foreman that he was tracking him about the mines, which any man would naturally dislike and which would tend to arouse resentment in his mind where, otherwise, none would exist.

The Successful Mine Superintendent

The successful mine superintendent must be broad-minded and possess a thorough knowledge of all outside work and equipment; but, above all he must be a practical miner rather than an accountant whose chief duty is to keep an accurate record of supplies and costs in and about the mine. The superintendent is the man to whom many questions and complaints are constantly brought by the women of the place, and tact and intelligence will be needed to handle these successfully.

One thing is certain, however, and that is a superintendent will make his foreman either like to see him come around or dread his appearance in the mine. When a foreman, myself, I always tried to keep clear of the superintendent who was continually telling me what he used to do when he was bossing. I have known superintendents who, no matter what bad conditions were presented, could always tell of having experienced worse conditions themselves in mines where they were in charge.

Such a superintendent thinks to spur his foreman on to greater efforts; but, in reality, he is discouraging him. The "super" who never sees anything that a

foreman has done to improve the mine, but is constantly looking for things with which to find fault, is no help to his foreman. Whether consciously or unconsciously, such a superintendent is a hindrance to the work.

When a foreman, with some very pardonable pride, shows his superintendent work that he has accomplished and is told "how it ought to have been done," instead of receiving the commendation he had a right to expect, the effect is to discourage him. It is, also, a bad idea to keep promising a foreman this or that, when the superintendent well knows there is little chance for the fulfillment of his promise, until conditions in the coal trade materially improve.

On the other hand, let a superintendent encourage his foreman in every way possible; commend him for a job well done and never take him to task or reprove him for his faults in the presence of his men. Be on speaking terms with all the men. A good word acts as a tonic and makes them better and more faithful workers. Even the trapperboy smiles to himself after the big superintendent has passed him with a good word. There are a thousand and one things that enter into the make-up of a good superintendent besides cost-sheets and figures. THOMAS HOGARTH.

McIntyre, Penn.

Letter No. 3—The incident narrated by William Gorman, *Coal Age*, Jan. 16, p. 159, regarding a barber who rose to a position of responsibility and trust in charge of a mine, reminds me of a similar case that I observed some time since. A man who had been a good grocer is now in charge of one of the most up-to-date and best producing mines in this vicinity. It is hardly necessary to add that, in his new position, he is making good.

While I am not in as close contact with mine superintendents as some of the other writers in *Coal Age*, I am in a position to observe many of their qualities that count either for good or for bad, in mine management. The results of my observation make me conclude that there is great need, indeed, for more efficiency on the part of the higher mine officials. Too often it happens that, as Mr. Gorman has suggested, these officials lack ability and experience. Frequently, the superintendent has one or more relatives, or friends belonging to his lodge, whom he keeps on the payroll simply because of such relationship and not for the work the man is capable of doing.

Loss in Efficiency Due to the Superintendent Overseeing Too Many Mines

One or two instances will illustrate the point I have in mind. A single large coal company, hereabouts, owns and operates five or six mines. There is but one superintendent in charge of all the mines, and it is a practical impossibility for him to keep in touch with these different operations, which are some distance apart. He is wholly ignorant of many things that are done in the mines and which lower the standard of efficiency by hindering the work and often causing absolute loss to the company.

At each of the mines, there is a mine foreman who has charge below, while a topboss is in full charge on the surface. It often happens that there is but little coöperation between these two underofficials, although the superintendent hears little of their differences.

For example, at one of these mines, it has long been the custom for the topboss to prepare and send down into the mine dry sand for the motormen to use on the sharp grades. One morning, recently, the sand was not sent down as ordered and the motormen were obliged to do the best they could. As a result, one trip got beyond control when descending a heavy grade. There was a wreck that ditched the trip, knocked out many timbers, tore up the tracks and delayed the mine for five hours. The mine foreman, however, knowing that the topboss was a relative of the superintendent, did not report the true cause for the accident. This left the management in ignorance of the real seat of the trouble.

Difference in Ways and Means of Doing the Same Thing in Different Mines

Another instance that can be cited shows a sharp contrast, in the efficient management of two of these mines, in respect to the handling and sharpening of the bits for the coal-cutting machines. In one of the mines, the dull bits taken from the machines are thrown into a box made of 4-in. pipe equipped with a lid, having a hook attached to hold it shut. This is an old-fashioned custom. Each machine may have three or four of these boxes, which are sent to the shaft bottom when full. There they remain until enough of the boxes arrive to be sent up on the cage. At the surface, they are taken to the blacksmith shop and sharpened when the smith has time. The system often causes much delay.

Compare the instance just cited with the arrangement in another mine, where a special truck is provided into which the dull bits are thrown. When full the truck is taken to the shaft bottom, hoisted on the cage and sent to the shop where the bits are sharpened promptly and again sent into the mine. In this case, also, the superintendent has no intimate knowledge of affairs and it would be an accident that would inform him of the different conditions in these two mines.

In the same two mines, also, different methods are in use for delivering power to the electric machines which are employed to cut the coal. In the first mine mentioned, the power is delivered by a separate, independent wire leading to the working face. This wire is poorly hung, lying or resting in any old way on its supports, while the dead or return wire is so covered up with slate, in many places, that it will never be recovered. Contrast this condition, now, with that in the second mine mentioned where the power for the coal cutters is taken directly from the trolley wires, and the return is through the rails which are properly bonded and examined every week.

In closing, let me say that the success of a mine official lies in his experience and education. An efficient and up-to-date superintendent is one who has derived his experience from actual work in the mines, which has made him familiar with what is required. Every good superintendent is constantly reading and studying new methods and, in my opinion, there is no better source from which to obtain this information than the columns of *Coal Age*, where many suggestions and much helpful advice are freely given for the asking.

Clinton, Ind. EFFICIENCY.

INQUIRIES OF GENERAL INTEREST

Pumping Water in a Shaft

I want to ask the assistance of *Coal Age* in solving a question in shaft pumping. The question is as follows:

A double-acting pump has a piston 6½ in. in diameter and a length of stroke of 4 ft. 6 in. The pump is located at the bottom of a shaft 250 yd. in depth. When the pump is running at a speed of 14 strokes per minute, how many gallons of water will it discharge up the shaft, and what will be the horsepower of the pump, assuming a useful effect of 60 per cent.?

This question is a practical one, and its solution has troubled me for some time past. STUDENT.

———, Alberta, Canada.

It is common mining practice to assume, for the purpose of estimate, that the water-end efficiency of a good pump is 85 per cent. of its piston displacement. The diameter of the pump cylinder, in this case, being 6½ in., its sectional area is $0.7854 \times 6.5^2 = 33.18$ sq.in. and, the length of stroke being 4 ft. 6 in., or 54 in., the piston displacement of this pump when running at a speed of 14 strokes per min., is $14(33.18 \times 54) = 25{,}084$ cu.in. per min. Therefore, taking the efficiency of the water end as 85 per cent. of the piston displacement, the discharge of this pump is

$$G = 0.85(25{,}084 \div 231) = 92.3 \text{ gal. per min.}$$

In calculating the "useful effect," which is the power that must be effective in the water end of the pump and which is here assumed as 60 per cent. of the power developed in the steam cylinder, it is not enough to consider the pump as operating under a head expressed simply by the depth of the shaft or, in this case, $3 \times 250 = 750$ ft. The depth of the shaft, or the distance from the water level in the sump to the point of discharge at the top of the shaft, is merely the "static head" or lift of the pump.

When the pump is in operation, there is developed, in addition to the static head, both a friction head and a velocity head. The velocity head, however, is generally small and can be wholly ignored, in mining practice, whenever the diameter of the column pipe, expressed in inches, does not exceed its length in hundreds of feet.

The friction head developed when a pump is in operation, however, depends on the diameter and length of the column pipe and the quantity of water handled per minute. It is necessary, therefore, to calculate the amount of this friction head and add it to the static head, in order to ascertain the actual total head under which the pump is to operate.

The friction head, h_f (ft.), for a discharge G (gal. per min.) and a length l (ft.) and diameter d (in.) of column pipe, is calculated by the formula

$$\text{Friction head,} \qquad h_f = \frac{G^2 l}{800 d^5}$$

Using a 2½-in. column pipe, which will handle the water discharged by this pump at an approximate velocity of 400 ft. per min. according to average coal-mining practice, and substituting the given values in this formula, the friction head developed, in this case, will be

$$h_f = \frac{92.3^2 \times 750}{800 \times 2.5^5} = \text{say } 82 \text{ ft.}$$

The total head against which this pump must operate is, therefore, $750 + 82 = 832$ ft.

Finally, assuming a useful effect of 60 per cent., as stated in the question, the horsepower required to be developed in the steam end of the pump, to perform the work mentioned, will be

$$\text{Horsepower,} \qquad H = \frac{62.5(231 \times 92.3)832}{0.60 \times 1728 \times 33{,}000} = 32.4 \text{ hp.}$$

This proposition is hardly complete without calculating the size of the steam end, or the diameter of the steam cylinder required to develop the estimated horsepower of the pump. The total pressure on the piston when the engine is developing 32.4 hp., and the piston speed is $14 \times 4\frac{1}{2} = 63$ ft. per min., is

$$p = \frac{32.4 \times 33{,}000}{63} = 16{,}970 \text{ lb.}$$

Then, assuming a steam pressure in the pump cylinder of, say 85 lb. per sq.in., the required diameter of the steam end of the pump is

$$d = \sqrt{\frac{16{,}970}{0.7854 \times 85}} = \text{say } 16 \text{ in.}$$

The size of this pump, to fulfill the specified requirements, will therefore be 16 x 6½ x 54 in., and is probably of the plunger type, which conforms better to the large ratio of the steam end to the water end necessary to overcome the great head on the pump, with a moderate steam pressure, assumed here as 85 lb. per square inch.

In order to maintain this assumed steam pressure, at the bottom of a shaft 750 ft. in depth, it will be necessary to allow for a drop of 5 lb. in transmission from the surface to the foot of the shaft, which will call for a gage pressure in the power house of at least 90 lb.

Also, is is estimated that this pump, under the assumed conditions, will consume practically 20 lb. of steam per min. But, if the steam pipe in the shaft is uncovered, there will result a loss estimated as 38 per cent. of the steam, by reason of the condensation caused by the radiation of heat from the bare pipeline in the shaft.

If the pipe is covered with asbestos, 1 in. in thickness, this loss by radiation of heat will be reduced to practically 5 or 6 per cent. In the former case, with the steam pipe uncovered, it will be necessary to provide for the generation of $(60 \times 20) \div (1 - 0.38) = 1935$ lb. of steam per hour, which would require a 60-hp. boiler for the operation of the given pump under the conditions mentioned.

With a covered pipe line, the loss by radiation of heat and consequent condensation of steam in the pipe is much less. Estimating this loss as, say 6 per cent., the steam delivered to the pump is $100 - 6 = 94$ per cent. of that generated, and a 40-hp. boiler would fill every requirement in that case.

EXAMINATION QUESTIONS

Alabama First-Class Examination, Birmingham, Jan. 20-23, 1919

(Selected Questions)

Ques.—What materials are best for tamping shots and why?

Ans.—A charge of powder placed in a drillhole should be protected by inserting a small wad of clay before proceeding to tamp the hole. The clay should be carefully pressed down against the charge and the hole then tamped thoroughly with some incombustible material. There is no better material used for this purpose than the fine dirt scraped from the roadways where the seam is underlaid with fireclay. The fineness of the dust and its incombustibility adapts it to the purposes of tamping a charge of powder.

Ques.—What is essential to the economical handling of coal?

Ans.—Economy in the handling of coal, from the working face to the tipple, depends largely on the style and character of the mine cars in use. They must be well built and mounted on good trucks equipped with roller-bearing wheels. The cars must be dustproof and of a kind that are easily loaded to their full capacity and can be readily dumped when they reach the tipple.

A good haulage system must be employed and the tracks kept in good condition so as to reduce the power required for haulage to a minimum. Wherever practicable, a storage-battery locomotive should be employed to haul the coal from the working face to the inside parting, where the trips are made up to be hauled out of the mine. It is possible, also, to use the same type of locomotive for hauling the cars to the shaft or slope bottom, or to the tipple, as the case may be.

Particularly in large mines with extended workings, a system should be established, in haulage, that will avoid unnecessary delays, both at the working face and on the road. A sufficient number of drivers or motormen should be employed for gathering the cars, and this work should be proportioned to that performed on the main road in hauling the trips to the mine entrance or tipple. A lack of proper proportionment, in this respect, will cause unnecessary delays and increase the cost of haulage in the mine.

The arrangements on the tipple for dumping should be such as to reduce the breakage of the coal to a minimum and load the cars for shipment as uniformly and regularly as possible, with the least expense for labor. The mine cars should be lubricated at regular intervals and inspected on the tipple each time a trip comes out of the mine. All cars needing repairs should be sent at once to the shop, and returned promptly to the mine when the repairs have been made.

Ques.—Describe the different kinds of brattices and overcasts in use; state how each is built; and say which you prefer and why.

Ans.—A brattice for conducting the air forward in a heading or room is built by standing a row of posts 8 or 10 ft. apart and 18 in. or 2 ft. from the rib. The line of posts extends from the last open crosscut forward in the direction of the working face. Thin boards or good canvas is then nailed to the posts on the side where the fresh air is traveling. Sometimes a slat or board is used to support the canvas stretched between two posts, so as to hold it well against the roof and prevent the leakage of air. The term "brattice" is often wrongly applied to a stopping built in a crosscut.

The most common form of overcast is built by blasting down the roof over the roadway where it is desired to construct the air bridge. This being done and the opening thus made being connected with the airway on both sides of the road spanned by the air bridge, iron girders or rails are thrown across the roadway and supported on the solid rib of coal on either side, so as to form a good foundation for the floor of the air bridge. Planks are then laid on these rails and the flooring thus formed covered with a good bed of concrete, care being taken to stop all holes and crevices through which the air would leak from the overcast into the airway below. It is necessary that the sectional area above the air bridge forming the overcast should be equal to the sectional area of the airways connected. An overcast is always preferred to an undercast, because it is free from the danger of being closed by an accumulation of water or gas, which would prevent the passage of men in time of need.

Ques.—What dangers are met in approaching old abandoned workings, and what precautions should be taken to avoid those dangers?

Ans.—There is always the danger that the old workings may be filled with gas, or that water may have accumulated therein to a dangerous extent. When approaching such old abandoned workings, it is not sufficient to examine the old mine maps and compare them with those of the present workings. No absolute dependence should be placed on the accuracy of the mine maps and surveys, particularly those of the abandoned mine, as such maps may not show the actual working face at the time the mine was abandoned, or there may be some error in the connection betwen the two surveys.

For the protection of the men driving a place approaching old workings, drillholes should be kept 16 or 20 ft. in advance of the place and flank holes should be drilled in each rib of the heading, which is kept 15 or 20 yd. in advance of its air-course. These flank holes should make an angle of 30 or 40 deg. with the rib, in the direction of the old works. A careful watch must be kept for any increase of gas or water, at the face of the heading. Where gas is suspected, safety lamps only should be used. Wooden plugs must be kept in readiness for instant use should one of the drillholes tap an accumulation of gas or water. In that case, the hole should be immediately plugged.

FOREIGN MARKETS AND EXPORT NEWS

Possible Market for American Coal in France

The post-war position of France with respect to coal supplies may make it possible to sell American coal in France during the year 1919. However, until there is some certainty regarding ocean freight rates it is impossible to say whether American coal can compete with English coal delivered in French ports.

Before the war the annual consumption of coal in France was over 60,000,000 tons, of which 40,000,000 tons were produced in the country. It is estimated that the consumption of France proper during 1919 will be in the neighborhood of 55,000,000 tons. Allowance is made in this figure for the reduced consumption of coal by reason of the destruction of thousands of manufacturing plants in the north of France. To this figure should be added, however, 8,000,000 tons which is the quantity of coal required to feed the iron, steel, and textile industries of Alsace-Lorraine, now in French occupation. This makes a total estimated consumption for France of 63,000,000 tons for the year 1919, or about the same as before the war.

It is hoped that French mines during the year 1919 will produce at least 30,000,000 tons of coal. This is slightly in excess of the quantity of coal mined in the year 1917. While there may be a slightly greater production for the year, as mines in the devastated regions gradually resume operations, it must be remembered that the labor needed to mine this coal will in all probability have to be taken from mines in the center of France, with a consequent reduction in the output of that section. There is also included in this estimate of 30,000,000 tons the coal that will be obtained from that portion of the Saar Basin lying in Alsace-Lorraine. The remaining 33,000,000 tons must be imported.

France hopes that England will be in position to export to her during 1919 close to 15,000,000 tons of coal. It is also expected that approximately the same quantity of coal can be imported from Germany during the year. However, if England is not able to export this quantity of coal to France this year, and if conditions in Germany should be such that a corresponding quantity can not be delivered to France, the French will have to look to the United States for whatever quantity is still lacking. Under the circumstances, it might be worth while for American coal exporters to look into the French situation a little in order to be in position to assist France in case of necessity.

Brazil Exporting Coal

According to the "Times of Argentina" Brazil has begun to export coal to Argentina. It will doubtless come as a surprise to many that Brazil possesses any coal mines worthy of comment, but the war has served in great measure to persuade the Latin-American countries to exploit their own resources. Quite a large syndicate is working a mine in the neighborhood of Rio Grande, and those interested in the venture express great hopes of being able to compete with English and American coal in the near future. The coal is said to be similar to lignite, but has a decided brownish appearance. It has been used as bunker fuel by some Brazilian steamers and is said to have given satisfactory results.

Argentina's Coal Imports

Imports of coal into Argentina in 1913 amounted to 4,046,278 metric tons, worth $27,332,611; in 1914, 3,421,526 tons, worth $23,112,407; in 1915, 2,543,887 tons, worth $17,192,644; in 1916, 1,884,781 tons, worth $12,721,695; and in 1917, 707,712 tons, worth $4,780,595.

As Argentina produces no coal of her own, a steadily increasing coal famine culminated in 1917, and produced a serious state of affairs for the railways, the industries and the domestic needs. At the beginning of 1917 the price was about $31 per metric ton of 2204 lb., but rapidly rose to $33 and $35 per ton, as against $8 in normal times. By July, 1917, it had risen to $40, and by the middle of June, 1918, to $50. Both maize and wheat middlings were used as fuel, especially the former, the surplus of which could not be exported. Charcoal and firewood rose to exorbitant prices because of the coal shortage, the former selling for $55 a ton and the latter for $17.50 to $18 a ton. Petroleum likewise showed a rapid increase in price, from $29.72 a ton in 1916 to $40.34 in 1917.

English Coal Market

Under date of Feb. 21 a London exchange states that the household coal market is in a critical position. The markets are almost bare, and special efforts are being made to obtain supplies in view of a strike in the mining regions. All descriptions of coal are firm on the Tyne and Wear, and the best Blythes sell readily at 90s. Gas coals are in keen demand.

House coal is still scarce in Lancashire, but more slack is coming forward at disproportionately high prices. Practically no coal is available in the open market in Yorkshire or the Midlands, owing to unfavorable weather and the strike menace. The latter greatly affects the position in South Wales. Production in Scotland is improving, and lessened Admiralty requirements leave a better margin for ordinary export.

In Newcastle the demand for tonnage far exceeds supply, and coastwise rates are firm on the basis of 17s. London. Scandinavian rates are rather easier. Quotations generally are firm in Cardiff.

The Italian Government has decreed the "temporary" abandonment of the projected state monopoly of the coal industry.

Foreign Freight Rates

W. W. Battie & Co.'s coal trade freight report for Mar. 3 states that shippers to Brazilian and Argentine ports are more than anxious for additional tonnage, but it is most unfortunate that the Shipping Board will not allow neutral steamers to be chartered for this voyage to American coal shippers on rates, as it is causing owners of these neutral boats to charter them on rates from Cardiff to east coast South American ports (some of them having accepted as low as 50/- gross from Cardiff to the Plata); consequently British shippers are selling coal which Americans would sell, if not restricted, as mentioned above.

The West Indian situation is the same as a week ago, and rates on general cargo from United States ports, north of Hatteras, to French Atlantic ports, are $40-$45 per ton net from charter, (on which terms we have recently chartered steamers), and unless coal can stand this freight rate, transatlantic shipments are impractical at the moment.

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis. Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge.

Sail (maximum) — Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net; Santos, $19.50 net; Buenos Aires, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. (Gross rates $1.50 per ton in excess of net rates). On all the foregoing rates, charterers pay vessel's towage to coal port. To Nitrate Range, $16.50 gross prepaid. (Same rate steam.)

The Chartering Committee's rate by steam is $19.50 net; with 1000 tons dis. to Rio, $19.50 net, 1000 tons dis., or $21, 600 tons dis. to Santos, $18.50 net, 1000 tons dis. to Buenos Aires, and $19.50 net, with 750 tons dis. to Montevideo.

England Losing Coal Trade

Normally, coal constitutes between 70 and 80 per cent. of the weight of British exports. Vessels bring bulky raw materials to the United Kingdom and take back manufactured goods of small bulk. Were it not for coal many vessels would have to leave British ports almost empty. In normal times, for example, the United Kingdom imports large quantities of raw materials from Argentina; in 1913 about 7,000,000 tons of British coal were shipped to Argentina. In 1918 British coal exports had fallen to one-half of the prewar standard. There has been a great increase in miners' wages, which accounts for two-thirds to three-quarters of the cost of coal at the pit mouth. Since 1914 the increase in miners' wages in South Wales has run from 87 to 200 per cent. It has lately been frequently pointed out that the higher prices of coal will both increase the cost of manufacture in the United Kingdom and make it more difficult for Britain to sell coal in foreign markets.

Coal and coke are still on the Export Conservation List of the War Trade Board. Individual licenses are not required for export of coal and coke to Canada and Newfoundland. Shipment to these destinations may be made under export license R.A.C.-63.

COAL AND COKE NEWS

Harrisburg, Penn.

The Attorney General of Pennsylvania has given an opinion to Seward E. Button, chief of the department of mines, in reference to Sec. 14 of Art. 4 of the Bituminous Mine Code of June 9, 1911.

Chief of Mines asked the Attorney General if Sec. 14 could be modified so as to hold that this section should apply only to mines that are gaseous in character. This section of the act of 1911 refers to blasting in the solid and that all holes shall be fired when all the workmen are out of the mine.

On Aug. 29, 1916, Deputy Attorney General Collins ruled that "shooting in the solid" should be allowed in all mines if it had been the practice before the code of 1911 became a law, providing that the mine foreman would allow it.

In the Huntingdon-Broad Top coal field, which is a non-gaseous district, considerable difficulty has been encountered in enforcing this section of the law by the state mine inspector, and several strikes have resulted. It is contended that it is impossible to mine sufficient coal during the night if the shotfirers must do all their work at night, as the veins are thin, of a heavy pitch and contain much slippery coal. The miners object to this method, also, as they claim they cannot mine enough coal, which naturally reduces their wages.

The point which the chief of mines wished to be enlightened on was whether or not the district inspector could use his discretion as to shotfiring at night, if the mine were of a non-gaseous nature, such as are found in the Broad Top field.

The Attorney General said he could not recede from the views expressed in the opinion of the Department given on Aug. 29, 1916, which said the Section referred to meant gaseous and non-gaseous mines.

The Attorney General concluded by saying, "It often happens that legislation, general in its character may work hardship in particular instances, and that its enforcement in special cases is difficult and impracticable. The remedy for such a situation is with the Legislature. The courts cannot construe legislation so as to make it applicable or inapplicable, according to the ease or difficulty with which it may be enforced, and the Attorney General is bound by the same rules of construction that apply to the courts.

"I am, therefore, compelled to advise you that notwithstanding the abnormal conditions in the Broad Top coal field, and the difficulty of enforcing the provisions of the law as heretofore construed, this Department is unable to place any other construction upon it than that indicated in the opinion of Deputy Atorney General Collins, dated, Aug. 29, 1916."

Uniontown, Penn.

Fire of undetermined origin entirely destroyed the coke-crushing plant of the General Chemical Co. at Newell. At this plant coke bought in the Connellsville region was crushed to ½-in. size to be used in filtering chemicals. The crushed coke was sent from the plant to plants of the company in all parts of the county. The plant will be rebuilt.

Shipments of coal down the Monongahela River maintained a high figure during February, the total being 20,271,000 bushels. While that figure is a decrease of 2,938,000 bushels over January, there were three less working days in February, making the daily average almost equal. The Pittsburgh Coal Co. is reported stacking coal at the Duquesne mills in anticipation of the annual conference of miners and operators scheduled for April. The Carnegie Steel Co. now has four boats supplying the Clairton byproduct plant, each boat making four round trips a week and delivering 96 barges containing 2,000,000 bushels. That company expects to put the "Edgar Thomson" in commission in a short time.

Although the Connellsville coke region is operating generally upon a 50 per cent. capacity there has been no labor disturbance and none is expected. The edge has been taken off an unemployment situation by operators turning a percentage of the men laid off to making sadly needed repairs at plants. Curtailment policy adopted when government prices were removed is still in force, although the tonnage of decreased production is becoming smaller each week. When the curtailment was commenced the average decline was 25,000 tons weekly. It has now been reduced to 8000 tons weekly, and it is expected that production will not go much lower than the present 225,000 tons, coke. Prices continue to remain firm with $4.50 ovens as the basis. A number of operators decline to move tonnage for less than $5 ovens, but some scattered coke is being sold as low as $4 ovens.

Charleston, W. Va.

Biding their time, coal producers of West Virginia are shutting down their mines in preference to letting fuel go below a reasonable price, believing that another 30 days will witness a decided change in market conditions.

Mar. 1 still found many mines closed down, as they had been throughout February, and in the first week of the month there was little to mark any change in conditions. Production is not averaging over 50 per cent. in any instance, and in many parts of the state mines are being operated on one-fourth time.

Coal shipments had dwindled to such an extent that the railroads operating in West Virginia have laid off many crews. A survey of the market by West Virginia producers, however, convinces them that reserve stocks which have been drawn on heavily during the last few months are reaching a low point, and at the same time there is no such accumulation of coal at tidewater shipping points as there was a few weeks ago.

Cognizant of such conditions producers feel certain that orders will begin to multiply now within a short time. There is some demand for prepared sizes and also for splint, gas and smokeless coal. No change in prices has been marked in recent weeks.

New York, N. Y.

The failure of the boatmen to come to terms with the private boat owners has led to threats by the longshoremen to tie shipping up completely in this harbor should the owners resort to efforts to break the strike with strikebreakers.

The strike of the boatmen for increased wages and an eight-hour day was half ended last Friday when several thousand of the workers employed on the boats operated by the Railroad Administration, Army and Navy and the Shipping Board agreed to accept a wage increase varying from 10 to 40 per cent.

The privte boat owners were not a party to that agreement and have refused to grant the demands of their employees. Several conferences have been held and it is said that propositions have been made by both sides. In the meantime boats loaded with coal are lying at the docks waiting for the strike to be ended before they can be towed to their destination.

These boats, which were chartered before the strike was declared, will be taken to their proper destination at the rate named in the charter and the rates for future deliveries will be agreed upon as the result of the negotiations between the boat owners and their employees.

Seattle, Wash.

The coal output in the state of Washington in 1918 totaled 4,128,424 short tons, the heaviest coal production in the history of the state, according to the final report of James Bagley, state coal mine inspector. The next biggest output was in 1917, when the total production was 4,002,750 tons. The first year in which the annual production exceeded 4,000,000 short tons was 1917.

The biggest gain in 1918 was made by Lewis County, where the increased production was 44,000 tons more than in 1917. The output by counties in 1918 was as follows: King, 1,331,601 short tons; Kittitas, 1,730,379; Lewis, 174,621; Pierce, 600,197; Skagit, 5897; Thurston, 271,400; Whatcom, 4603. The output by counties in 1917 was as follows: King, 1,314,366; Kittitas, 1,741,237; Lewis, 130,578; Pierce, 606,049; Skagit, 1000; Thurston, 204,688; Whatcom, 4841.

Seventy-two coal mines were operated in the state in 1918, working an average of 266 days and employing 5847 men. There were 34 fatal accidents during the year. In 1917 there were 27 fatal accidents. The increase in fatal accidents last year was due to an accident in the Burnett mine in August, 1918, in which 12 men lost their lives. There were 692 non-fatal accidents last year as compared with 1025 in 1917.

Mr. Bagley says that the present indications are that the output of coal will not be as heavy in 1919 as last year. He attributes the increased output last year as being largely due to high pressure caused by war conditions.

Though it will be easier to secure coal from now on and consumers have been relieved of restrictions that prevented a free use of fuel, it is declared by state representatives of the Federal Fuel Administration that there is no likelihood of an easing off in price regulations.

The withdrawal of numerous Government demands for coal is said to be responsible for the change in regulations in effecting distribution. Some of the heavy requirements of foreign governments also have been satisfied (notably Chile, which has been taking much Washington coal for the past several months), or have been withdrawn, and coal is certain to be more plentiful than was anticipated at the beginning of winter.

Victoria, B. C.

Some interesting new facts were brought to light by Hon. William Sloan, Minister of Mines, in speaking before the Provincial Legislature to the "Settlers' Rights Act, 1918," which proposes giving those holding property within the Esquimalt & Nanaimo Railway Belt, Vancouver Island, a further opportunity to make applications for their coal rights on the land to which they have surface title. He stated that there were some 45 or more applications for such coal rights dealt with under the Settlers' Rights Act of 1904, which measure first opened the question by legislation, and that altogether Provincial titles had been granted to 7166 acres of coal-bearing land within the boundaries of the railway holdings on the Island.

Mr. Sloan pointed out that when the railway was first given title to these Island lands it had been granted an additional 86,346 acres to recompense it for property which had been alienated to settlers prior to 1884. He stated that to repay the company for the 7166 acres of coal-bearing land taken subsequent to 1904 another 20,000 acres had been deeded to the company. Of the total 2,210,000 acres which, it was computed, was included in the Esquimalt & Nanaimo Railway Belt, it was roughly estimated that there were 356,000 acres of a coal-bearing character. It followed that there still remained to the railway company or its successors some 366,000 acres of coal-bearing lands.

The debate on the proposed 1918 act is still in progress, but it is considered likely that it will be carried. Under its terms the settlers, or their heirs, will be allowed to apply for the coal rights on their lands and, if successful in proving that they have a legitimate claim, will be issued Provincial titles. All this, however, is contingent on the stand taken by the Dominion Government. The latter exercised its prerogative last year and vetoed, or disallowed, the 1917 act, which was of an exactly similar nature. The contemplated action of the Provincial Government in taking the earliest opportunity to reënact the legislation which, apparently, is repugnant to the Federal Administration has created an interesting situation. It would seem that a determined fight has been launched between the Province and the Dominion, it being the contention of the former's government that the Dominion is infringing the authority of the Provincial Legislature in assuming to dictate on a subject affect-

ing nothing more than "Property and Civil Rights." Jurisdiction to handle all matters coming under that heading was clearly alloted to the Provinces under the Terms of Union.

PENNSYLVANIA

Anthracite

Mauch Chunk—Instead of the Lehigh Coal and Navigation Co. entering into an agreement with local firms, as in former years, to take the drifted coal from the dams throughout the Lehigh Valley at a certain royalty per ton, the company is erecting a washery here itself and will take out the coal and market it. Thousands of tons of coal have been reclaimed annually for many years in this way.

Avondale—Ten men were almost overcome while engaged in fighting the old Jersey mine fire at the Chauncey colliery of the George F. Lee Coal Co. on Mar. 5. Prompt arrival of the Delaware, Lackawanna & Western, Coal Department, rescue car saved many of the victims from death. The "Jersey Fire" originated about 20 years ago and after several unsuccessful attempts to extinguish it were made the fighting of the fire was given up until a few weeks ago, when its spreading endangered the Avondale colliery workings. The Lackawanna Coal Co. placed a force of men at work, some on the outside and some within the workings.

Bituminous

Somerset — The Loyalhanna Coal and Coke Co. has been investing in tracts of land in Shade township, deeds recorded showing transfers of a number of individual tracts.

Black Lick—The switch points and railroad connection with the siding of the Smith Coal Co. here were made recently, and shipments from the new mines will be begun in a week or so.

Philipsburg—The Lena Coal Co. has recently been organized and has taken over the new Goodyear shaft at Smoke Run. It is the intention of the company to develop the property to its utmost capacity.

Somerset—The Tri-State Collieries Co. has recently completed negotiations for the acquirement of a tract of coal properties in Somerset County aggregating approximately 2850 acres.

Connellsville—According to figures issued by the various mine inspectors located in the coke region the tonnage made large gains in 1918. The 16th district had a production of 8,867,477, the 9th district 7,189,946, the 5th district 7,011,189, and the 2d district 6,484,742.

Washington—The Lilley Coal Co. has purchased 2300 acres of coal lands lying east of this city. It is thought the tract will be mined for shipment over the Monongahela River. This block of coal connects with one already owned by the Lilley company. The company now owns about 3400 acres.

Blairsville—T. L. Eyre, of Chester County, and Wilbur P. Graff, of Indiana County, have pooled their coal-mining interests in this section under the name of the Kiskiminetas Coal Co., with offices at Blairsville. The consolidated company was formed from the old Kiskiminetas and Roaring Run mining companies.

Springhill — The Winstead Coal Co., Springhill Township, Fayette County, has recently completed plans for the construction of a new coal tipple on the right bank of the Monongahela River, about 1 mile above Lock No. 8. The company has been granted permission by the State Water Supply Commission for the erection of the proposed structure.

Ernest—The Roman Catholic church here was totally destroyed by fire on Mar. 6. The fire is thought to have originated from one of the candles which was left burning by the altar boy, probably igniting some of the draperies. By heroic work on the part of the miners the new parish house, which is but a few feet away from the church, was saved. The church was built a few years ago mainly through generous gifts from the leading officials of the Jefferson and Clearfield Coal and Iron Company.

Greensburg—Coal values in the several Westmoreland County fields were fixed here by the county commissioners for the next three years. Connellsville coking seam is assessed at $900 an acre; the Irwin, Youghiogheny and Monongahela basins at $450; the Greensburg field at $600; Latrobe, north of the Pennsylvania R.R. at $550, and south of the railroad at $800; Ligonier basin, $500; Kiskiminetas Valley, $450, while the Freeport vein was placed at $60 to $100, according to the location.

Herminie—Fire broke out in the large store of the Eureka Supply Co. here recently and totally destroyed the building and contents. The loss is estimated at $75,000 to $100,000. The building was a brick structure and modern in every respect. Besides the store on the first floor there were four living apartments on the second floor. The occupants lost everything. The flames spread to the post office on one side and a company house on the other side of the store. Damage was inflicted upon both, but hard work by miners saved them from total destruction.

Brownsville—The Atlas Coke Co. has closed down its mine and 220 coke ovens at Waltersburg, Penn., indefinitely, on account of lack of orders. There are about 500 more ovens in the Connelsville region on the inactive list than a week ago, and no seeming immediate prospect for revival, although there seems to be a general feeling of optimism that the depression will not last for long.

It is rumored that the Pittsburgh Steel Co., operating a large plant at Monessen, Penn., on the Pittsburgh & Lake Erie R.R. and Monongahela River about 40 miles above Pittsburgh, is arranging to take over the coal and coke operations of W. Harry Brown. These operations consist of two plants in Fayette County, Pennsylvania, on the Monongahela R.R. and the Monongahela River, a few miles above Brownsville, and are operations in Greene County. The plants are large and modern.

MARYLAND

Frostburg—Working conditions are improving in the Georges Creek region. The Broken Heart mine of the Union Mining Co., which has been idle for some time, has resumed operations in full, while all mines of the Consolidation Coal Co., with the exception of No. 9, operated in full all last week for the first time in many weeks. Mines generally are now working with more regularity.

WEST VIRGINIA

Wheeling—Fire recently entirely destroyed the tipple and boiler house of the Mound mine of the J. C. McKinley group of mines near here. Mr. McKinley plans to replace the structure destroyed without delay.

Clay—In connection with the construction of a plant near here, the Lima Coal Co. has made arrangements to install a bucket conveyor system in order to get its coal across the Elk River to the Coal & Coke Ry. for shipment.

OHIO

St. Clairville—The Roby-Somers mine has closed down until May 1, it is said.

Martin's Ferry — The Burlington Coal Co.'s mine here has been sold to the Commonwealth Coal Co. of Pittsburgh. The Burlington company employs about 50 men.

INDIANA

Bicknell—The Pan Handle Coal Co. is building a complete new steel tipple, equipped with the most modern horizontal coal screens. The Krehbiel Co., engineers, of Chicago, have the contract.

Linton—The Coal Ridge Mining Co. is installing a coal preparation plant at the No. 1 mine. The plant is being equipped with modern horizontal screens and crusher. A substation is also being installed for furnishing direct current for locomotives.

ILLINOIS

Clinton—The wood tipple at the Keller Klondyke mine, three miles northwest of the city, was destroyed by an explosion on Feb. 27. The blast was of a peculiar nature, presumably a dust explosion. Such was the force of the explosion that the tipple was torn from its anchorage. A force of men was put to work immediately to rebuild the tipple. Splendid progress was made in the work of reconstruction, and at this writing 75 of the employees of the company have resumed work.

Carlinville—The first cage in the Berry mine, or more properly speaking, Mine 1-B, has been hung. The new equipment is being placed in position as rapidly as possible and the company hopes to begin hoisting coal on St. Patrick's Day.

Carlinville—The Standard Oil Co. made an excellent record at Mine No. 1 in February, the best which it has made since it took over the mine. The output was approximately 25,000 tons, which was hoisted in 24 working days.

Rutland—The tower of the coal mine here was destroyed by fire. About 75 men are idle as a result. The loss is covered by insurance.

Taylorville—The Peabody Coal Co. No. 9 mine at Callaway will be ready in about three months for the erection of the new top works, which will be of steel. The mine will be electrically equipped throughout.

Herrin—The Big Muddy Coal and Iron Co.'s mine No. 8 at Clifford is undergoing a thorough overhauling. An entirely new boiler plant is being put in and it is understood that a new washer will be built or the old one entirely remodeled. New motors and extensive work on the haulage system are also being installed. This mine has been idle for some time for repairs.

Maryville—The local record for hoisting coal in this district was broken on Mar. 3 when the Maryville mine of the Donk Brothers Coal and Coke Co., of St. Louis, hoisted 4265 tons of coal in eight hours. The state record, it is understood, is held by the Orient mine in Franklin County, which has produced 6000 tons in eight hours. The Maryville mine had 507 men, including 300 diggers, at work when the record was made.

Mascoutah—The old mine of the Kolb Coal Co. broke its coal-hoisting record recently by making 834 hoists, the old record being 785 hoists. This is the largest amount of coal ever taken out of this mine in one day, the actual hoisting time being seven hours. The coal was all caged and dumped by hand, as the old-fashioned stiff cages are still in use in the mine. This mine has been in operation for 24 years.

Collinsville—The annual convention of sub-district No. 7 of the Illinois Mine Workers will be held in the new Miners' Institute building here Mar. 18. Among the subjects to be discussed will be the six-hour mine day, the daylight saving law, the Mooney case and proposed changes in the safety measures for protection of miners.

Taylorville—Coal has been struck in two places in Mosquito township near here. One of the prospects is on the Emil Watts farm where it is said that seams of five and seven feet have been struck at a depth of 550 feet. The other is on the Loren Butterfield farm, where the conditions are about the same. The company developing the operations has options on 30,000 acres at $15 an acre.

Alton—The Gillettes, coal operators and cattle raisers of Logan County, have been making extensive purchases of coal lands in this vicinity with the understood purpose of doing development work on a large scale. About 1000 acres have been purchased at Miles station, for which about $150,000 is said to have been paid. The Gillettes utilize the surface for stock raising and therefore do not confine themselves to purchase of the coal rights. There are known to be good deposits of coal under the land which has been purchased.

IOWA

Des Moines—Iowa bituminous coal mines are being operated on an average of only two days a week. The failure of many railroads to take more than their minimum contract quotas and the unusually mild winter are given as the two underlying reasons for the condition of slack work at the mines. J. C. Lewis, of Albia, president of the Iowa mine workers, estimates that normally the railroads purchase 10 per cent. of all of the coal mined in the state. The mine workers state that some railroads which in other years used Iowa coal for operating in this state and Nebraska are now consuming Illinois coal and are carrying it into Nebraska for use in that state. It is said that five mines in one section which have a normal daily production of 3500 tons, previously used almost entirely by the railroads, now sell only 300 tons daily to the roads. More than nine million tons of coal were produced in Iowa in 1917, but several months of slack work cut down the 1918 production. The production for 1919 promises to be greatly under the 1917 yield unless there is a marked improvement in the situation. Many miners have left the state on account of the lack of work. Approximately 14,000 miners are employed in the state, and with an average of only two days' work a week they are earning about $10 a week. The slack work offered has proved to be a hardship to many miners and hundreds of them have been forced to part with their Liberty Bonds.

COLORADO

Boulder—Fire which started Feb. 28 in the Centennial mine of the Big Four Coal Co. at Louisville, near here, destroyed surface buildings of the mine. Six men who were inside when the fire began were rescued. The loss has not been estimated.

Aguilar—The new bathhouse of the Royal mine, near here, is proving a boon to the employees. The structure is of concrete, nicely painted, and accommodates 132 individual lockers. The bathhouse is electric lighted and is equipped with 14 showers and hot or cold water-steam baths. It is strictly sanitary, being thoroughly scrubbed and cleansed each day. The building was erected at a cost of $3000. The Royal Fuel Co., of Denver, Colo., which operates a number of mines, has constructed similar houses at its other plants.

Personals

Frederick J. Kandt, of Buckhannon, W. Va., has succeeded Mr. Slattery as Fairmont (W. Va.) manager of the Alden Coal Company.

W. H. Cameron has resigned his position of general manager of the National Safety Council to become manager of industrial relations for the Eastman Kodak Co.

Thomas Richardson, formerly with the Dilltown Smokeless Coal Co. at Dilltown, Penn., has accepted a position as superintendent with the Park Coal Co. at Leechburg, Penn.

C. C. Wallace, formerly manager of the loading of munitions section of the Stenotype Co., Indianapolis, Ind., is now director of development and service of the Powdered Coal Engineering and Equipment Co. of Chicago.

R. E. McLain has been made superintendent of the Peabody coal mine at Stonington, Ill., succeeding Mr. Anderson. Mr. McLain has been superintendent of the Hewittville coal mine for the past two months.

Calvin Horning, formerly mine foreman for the Rochester & Pittsburgh Coal and Iron Co., at Lucernemines, Penn., has been made superintendent of the Coy mines of the Brush Creek Coal Mining Co. at Homer City, Penn.

G. P. Blackston (L. W.) has resigned from the Koppel Industrial Car and Equipment Co., of Koppel, Penn., after having been with the company for nearly twelve years in the capacity of advertising and promotion of sales manager.

George K. Bell, special legal investigator of the Interstate Commerce Commission, has succeeded F. J. Patton, former secretary of the Northern West Virginia Coal Operators' Association. Mr. Bell's title will be that of executive vice president.

Henry T. Bannister, state mine inspector of Franklin County, with headquarters at Benton, Ill., has resigned to accept a position as production manager for the Madison Coal Corporation. His successor as state inspector will be **John O'Rourke,** who is the present county inspector.

Capt. A. U. Wetherbee, who recently received his discharge from the chemical warfare branch of the service, and who was formerly chief engineer and assistant works manager of the Niagara Alkali Co., has accepted a position as chief mechanical engineer with the Powdered Coal Engineering and Equipment Co. of Chicago.

J. William Wetter, chief engineer of the Clearfield Bituminous Coal Corporation at Clearfield, Penn., has resigned that position to become assistant general manager of the various mines in the Pennsylvania anthracite and bituminous fields and the West Virginia field of Madeira Hill & Co. Mr. Wetter will have his headquarters at Philipsburg, Penn.

C. W. Johnson has been appointed assistant manager of works of the Westinghouse Electric and Manufacturing Co. Mr. Johnson entered the employ of the company in 1907 as chief inspector of works. He is a member of the American Society of Mechanical Engineers, American Institute of Mining Engineers and Engineers' Society of Western Pennsylvania.

Henry D. Thompson, formerly superintendent for the Big Muddy Coal and Iron Co.'s properties at Herrin, Ill., has been appointed state mine inspector by Governor Lowden. It is expected he will be assigned to the Williamson and Franklin County fields. His father is the head of the Department of Mines and Minerals in the State of Illinois, succeeding the late Evan John.

C. W. Price, field secretary of the National Safety Council, was elected general manager of the society at a recent meeting of the executive committee, to fill the place made vacant by the resignation of **W. H. Cameron,** mentioned elsewhere in these columns. **Sidney J. Williams,** formerly manager of the accident prevention division was elected secretary and **F. W. Pardee,** formerly business manager, was elected treasurer.

Obituary

Edward H. Vitalius, chief engineer of the American Blower Co., Detroit, Mich., died Feb. 26 as a result of injuries received in a trolley wreck. Mr. Vitalius was well known as an expert in ventilation problems.

Coming Meetings

New England Coal Dealers' Association will hold its annual meeting March 19 and 20 at Worcester, Mass. Secretary, C. R. Elder, Boston, Mass.

Indiana Retail Coal Merchants' Association will hold its annual spring meeting Apr. 23 and 24 at Indianapolis, Ind. Secretary, R. R. Yeagley, Indianapolis, Ind.

National Foreign Trade Council will hold its sixth convention at the Congress Hotel, Chicago, Ill., April 24-26. Secretary, O. K. Davis, 1 Hanover Square, New York City.

Industrial News

Barnesville, Ohio—The Millwood Coal Co. has been chartered with a capital of $50,000 by Ellis G. Eyer, Robert G. Scott, E. M. Johnston, T. S. Lackey and James W. Bell.

Canton, Ohio—The Diamond Coal Co. has been incorporated with a capital of $25,000 by H. G. Winterhafter, L. P. Winterhafter, William I. Zink, Ray F. Harbert and William R. Thom.

Dayton, Ohio—The Robert H. Ball Coal and Mining Co. has been chartered with a capital of $150,000 by Robert H. Ball, James H. Anderson, John Gallagher, Sidney G. Kusworm and Alfred J. Goldshot.

Buffalo, N. Y.—The office of the Youghiogheny & Ohio Coal Co. will move from the Marine Trust Building to the Prudential Building. R. A. Kreuger, sales agent, has resigned to accept a more lucrative position. He will be succeeded by A. J. Kretchmar, from the office of the company in Cleveland.

Columbus, Ohio—Due largely to the opposition of organized miners, the bill introduced in the Ohio Legislature providing for the organization of a state constabulary was killed in the senate. At a recent meeting of sub-district No. 4, United Mine Workers, strong resolutions against the measure were adopted.

Hartford, Conn.—The Terry Steam Turbine Co. makes the announcement that since the death of Charles E. Hague in April, 1917, its interests in the Philadelphia district have been under the supervision of V. L. Sanderson, with headquarters at 605 Widener Building. James H. Weir has recently become associated with the concern as assistant to Mr. Sanderson.

New York, N. Y.—While no formal announcement has been made, it was stated at the Army offices that the Alden Coal Mining Co. would furnish 35,000 tons of coal for the transport service in New York harbor. Bids were opened here on Feb. 10 for supplying about 300,000 tons of coal at the rate of about 60,000 tons a month for five months. There were 20 bidders. The Alden Coal Mining Co. submitted bids on two delivery periods (Coal Age, Feb. 20, page 381).

Seattle, Wash.—The closing down of the shipyards in Seattle and vicinity through a general strike of the metal workers has caused an influx of men to the coal mines, which have been running short-handed several months because of the fact that many coal miners, attracted by higher wages, left the mines for the shipyards. This shortage before the close of the year was as high as 1200 men, but it has now been reduced to less than 200 men. The shipyards have been closed for two months.

Charleston, W. Va.—A total of $1,350,000 is said to have been the consideration involved in the transfer of ninety different tracts of coal land in Nicholas County from the Gauley Coal Land Co. to the new Gauley Corporation, this constituting a sale of the greatest magnitude so far recorded in Nicholas County. It seems likely that some of the coal in this acreage which has changed hands will be developed, as the Gauley company has deeded certain rights of way to the Kanawha & Michigan Railway Company.

Harrisburg, Penn.—Official figures placing the total value of all unmined coal in Dauphin County at $117,499,536 were submitted to the Board of County Commissioners on Mar. 3, by T. Ellsworth Davies, of Scranton, mining engineer, who has completed a survey of the Lykens coal fields in this county. At present the coal field valuation for this county is assessed at approximately $1,000,000. If the new valuation will stand in many little mining towns of a hundred or so population, the tax collectors of the same will receive from $5000 to $19,000 in commissions.

St. Louis, Mo.—Walter A. Zelnicker, president of the Walter A. Zelnicker Supply Co. and affiliated companies in St. Louis, has appointed Cline B. Finnell as his private secretary. Mr. Finnell, who recently returned from the Officers' Training School at Camp Pike, Ark., was formerly traveling secretary to the general superintendent of the Chicago, Burlington & Quincy R.R., and later private secretary to Clarence H. Howard, president of the Commonwealth Steel Co. Mr. Finnell is president of the Junior Chamber of Commerce of St. Louis, an organization of 1000 members of younger business men of the city.

Columbus, Ohio—F. S. Davidson, who has been connected with the West Virginia Coal and Coke Co. for several years in the capacity of office man, has resigned to become sales manager of the Pittsburgh & Bessemer Coal Co., of Pittsburgh, which will establish sales offices in Columbus. The Columbus office will be located in rooms 322-323 Columbus Savings and Trust Building. The company controls the Kehota Mining Co., which has a stripping operation in the Hocking Valley. Curtis T. Posten, formerly with the Consolidation Coal Co. as a traveler, has taken the position of M. Davidson with the West Virginia Coal and Coke Co.

Pittsburgh, Penn.—The Vesta Coal Co. has made announcement that work has recently been completed on the construction of the company's marine way on the Monongahela River, at Floreffe, about 24 miles from Pittsburgh. The new ways are of concrete, the six cradles being of steel, with length sufficient to hoist a 250-ton and a 150-ft. barge at one time, end on end. Seven platforms have also been constructed, providing enough space to accommodate barges of the above-named length or four towboats at one time. The equipment at the new marine ways is electrically operated throughout wherever possible. The company is a subsidiary of the Jones & Laughlin Steel Co.

Quincy, Ill.—The Dayton-Dick Co., manufacturer of centrifugal pumps, has changed its name to the Dayton-Dowd Co. The change was made owing to changes in organization. Capital has been doubled and the business placed directly under the control of those immediately interested. Facilities are greatly extended. The company has recently received many orders for large irrigation and drainage pumps, and it can now build any size from 1½ in. to 30 in. in a split-casing type of pump. It has developed a complete line of fire pumps, complying with specifications of the various underwriters' boards. Furthermore, it has developed high-pressure and hydraulic pumps for boiler feed, elevator pumps and similar high-pressure service, and these lines are to be pushed to the utmost.

Fairmont, W. Va.—There will be no further delay in completing the plant of the Domestic Coke Corporation, capitalized at $5,000,000. A little less than a year ago this concern was organized by people identified with the Monongahela Valley Traction Co. in coördination with the Government not only for the purpose of manufacturing byproducts but also explosives for the Government as well. Upon the signing of the armistice construction work ceased, the Government having no further use for the product of the plant; but it became necessary to determine the Government's financial responsibility before work proceeded further on the plant. Government accountants having audited the accounts of the company, orders have been received from Vice President C. F. Critchfield of the company to proceed with construction work. In accordance with such instructions the battery of 60 byproduct ovens which will become the first unit of the plant will be finished at the earliest possible date at a cost of about $3,000,000, each byproduct oven to cost $50,000. The ultimate cost of the plant will be $5,000,000.

MARKET DEPARTMENT

Weekly Review

Improvement Is Evident in Bituminous Situation—Prices Being Maintained, the Best Grades Having Gone Up—Production of Soft Coal Increases—Anthracite Situation Unsettled—Higher Price Schedule Announced

SIGNS are not wanting that the bituminous coal market is now on the mend, and both prices and production are already beginning to reflect the change in conditions. Coals of good quality are not being sold at less than the recent Government prices, and operators, as a rule, are adhering closely to their policy of producing only what the market will absorb. One of the many indications that the soft coal market is settling down to a normal basis is the fact that the special grades of bituminous coal command much higher prices than they did during the period of Government control. Inferior coals are finding it more difficult to obtain a market, buyers in the majority of instances exercising the keenest sort of discrimination. They have had a sorry experience with poor coal.

Needless to say, operators in all the producing districts are watching the current market conditions closely. Efforts are many to close contracts for the next coal year—Apr. 1, 1919, to Mar. 31, 1920—but no agreements involving any considerable tonnage have been reported.

The continued drop in the output of soft coal for the last six weeks was checked during the week ended Mar. 1 by the production of 8,088,000 net tons, an increase of more than 363,000 net tons over the output for the week ended Feb. 22. As compared to the production of the similar period in 1918, however, this is a drop of 3,519,000 net tons. Total production of soft coal for the coal year to date is 525,517,000 net tons, 20,168,000 net tons in excess of the output for the same period of the preceding coal year. It is recognized that March will be another light month for tonnage, but orders are more numerous than they were a week or two ago. If the situation continues to show the same signs of improvement for another month or so, without the injection of labor troubles at the mines, the soft coal industry will have passed undemoralized through its readjustment period.

"Unsettled" is the word that best characterizes the present condition of the anthracite industry. Even with the mines working only half time the operators find it difficult to dispose of their output. Instead of the decrease in prices loudly heralded in some quarters, the announcement has been made that beginning with May 1 there will be an increase in the price of domestic anthracite of 10 cents a ton each month until a maximum increase of 50 cents a ton is reached on Sept. 1. The so-called "independent" companies will increase their prices during the same period 15 cents per ton, making the maximum for independent coal 25c. higher than for company coal on Sept. 1.

The production of anthracite during the week ended Mar. 1 is estimated at 1,102,000 net tons, a slight decrease over the preceding week's output, but 834,000 net tons lower than the production during the corresponding week in 1918. The total output of anthracite for the coal year to date is 87,122,000 net tons.

WEEKLY COAL PRODUCTION

For the first time during the past six weeks improvement occurred in the output of bituminous coal during the week ended Mar. 1, preliminary estimates placing the production at 8,088,000 net tons, compared with 7,715,000 net tons during the week ended Feb. 22. This increased output, however, is 3,519,000 net tons below the output of the week of Mar. 1, 1918. The average production per working day during the current week is estimated at 1,348,000 net tons, as compared with 1,825,000 net tons for the coal year to date, and 1,755,000 net tons for the same period of last year. Total production for the coal year to date totals to 525,517,000 net tons, and is now but 20,168,000 net tons in excess of the output for the period Apr. 1, 1917, to Mar. 1, 1918.

The production of anthracite in the United States during the week ended Mar. 1 is estimated at 1,102,000 net tons, and while a slight decrease compared with the production of Feb. 22, falls far behind production during the corresponding week of last year when the output was recorded at 1,936,000 net tons. For the coal year to date production of anthracite is estimated at 87,122,000 net tons, as against 91,173,000 net tons for the eleven months ended Mar. 1, 1918.

Carrier's reports for the week ended Mar. 1 show that improvement occurred in all districts with the exception of central and western Pennsylvania and southwestern Virginia. The decreases that occurred in these fields were slight, while the increased loading which occurred in Ohio amounted to 758 carloads, in the southern West Virginia field to 1756 carloads and in the Illinois, Indiana and Western Kentucky fields to 2765 carloads.

Bituminous coal shipped to New England during the week ended Mar. 1 is estimated at 238,885 net tons, and is a slight decrease compared with the week preceding. Shipments by rail were in excess of those of the week preceding, while tidewater shipments fell approximately 14,000 net tons. No tonnage was loaded at Baltimore during the week.

Shipments of bituminous coal from the North Atlantic ports and Hampton Roads to all points during the week ended Mar. 1 are estimated at 567,782 net tons, a decrease compared with the week of February 22 of 24,715 net tons. The coal moved from New York and Philadelphia, estimated at 305,217 net tons, was 46,235 net tons behind the week of Feb. 22, while the tonnage moved from Baltimore and Hampton Roads exceeded that of the preceding week.

Production of beehive coke in the United States during the week ended Mar. 1 is estimated at 436,365 net tons, as against 445,692 net tons during the week ended Feb. 22 and 621,482 net tons during the corresponding week of 1918. During the current week production in Pennsylvania, West Virginia, Virginia and Kentucky fell behind that of the week preceding, while production in the other states was in excess. Compared with the same week of 1918, however, the current week's production in all states falls far behind. The daily average per working day during the week of Mar. 1 is estimated at 72,727 net tons, and is considerably lower than the daily average for the calendar year to date, estimated at 83,418 net tons, and the daily average for the same period of last year, estimated at 89,780 net tons. Pennsylvania is the lone state reporting production, for the calendar year to date, in excess of last year.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running slightly less than for the same week of 1919. Road sales for at-once delivery also were less compared with the same period last year. Few customers were in the house. Collections continue normal.

Dry Goods Economist—One of the factors which have much to do with the lessened production of all textiles is the unrest of labor. In the cotton mills of New England, the woolen mills of New Jersey and other states, and the silk mills of New Jersey and Pennsylvania, as well as in the knitting mills in and around Cohoes, N. Y., the demands of labor have been such as to curtail production or to increase its cost. In the women's garment industry, strikes have also been a deterrent to normal production, but have not had the effect of retarding business to any marked degree.

Bradstreet's—Conservatism and caution still dominate the general trade situation, but absolute necessity buying and the advance toward spring are visible in the reports of a larger volume of buying at both primary and secondary markets, northwestern and large southern cities sending best reports. Industry, except in a few lines, and these chiefly textiles, also shows a slightly better pace, and many readjustments appear to have been satisfactorily completed. Perhaps the most notable advance, industrially, visible is the swelling of the building trades into a modified form of preparatory activity after over a year of dullness and depression and even starvation treatment forced by war necessities.

The Iron Age—Producers are, if anything, more outspoken in the expectation that labor readjustment will be necessarily long delayed. This and the commonly overlooked fact that this country's industry will not move independently of the rest of the world promise little in the way of drastic price revisions. February's production of pig iron was 2,940,168 tons or 105,006 tons per day. This is 1519 tons less than the daily output of January. On Mar. 1 there were 306 furnaces in blast making iron at a rate of 101,475 tons daily, against 323 furnaces on Feb. 1, operating at 104,405 tons. In the month improved furnace operation was obtained, due probably to better coke. One group made 4000 tons more in the 28 days of February than in the 31 days of

January, notwithstanding there was a net loss of four furnaces in blast by Mar. 1.

American Wool and Cotton Reporter. From orders taken on woolen goods offered in New York, good business seems to be in prospect for the woolen mills. The worsted mills are generally keeping out of the market on account of the labor situation and the lack of choice wools, but a few orders have been received from them. The opinion is expressed that wools from the Middle West which were 65 to 70c. last year will open at 50c. this year. Others feel that prices will be about 50 per cent. of what they were a year ago. News from the South in regard to reduction in cotton acreage is attracting close attention. Although previous attempts have not met with any degree of success, it would seem as if this year efforts will be more effective than they have in the past. Opinion is divided as to to the ultimate result of the strenuous efforts to reduce acreage, both among manufacturers and also in the South. Mill demand for cotton has been small.

Atlantic Seaboard

BOSTON

Signs of a better tone. Transient demand improves all-rail, although tonnages are small. Prices show firmness. Contracts offered, and in some instances accepted. Operators watch market closely. Shipping Board withdraws all rates and will return steamers to owners. No activity on Hampton Roads coals, and none looked for until June. Contracts offered by rehandlers for points inland. Anthracite dull except for scattering demand because of lower water rates. Railroad-owned barges at disadvantage. Rail movement slopes off. More confidence in mine prices.

Bituminous—Unmistakably there are distinct signs of an improved situation. The change is extremely slight, but there is a more hopeful undertone than has been apparent the past 60 days. Things are beginning to settle, if ever so little, and each week now brings us nearer a season basis. The big news this week is the reopening of a competitive market on marine freights, and this will go far to restore confidence in the trade for the new coal year.

Inquiry for spot coal, or rather for transient lots, has improved noticeably the past week. The tonnages are small, but in the aggregate amount to a considerable volume, and are the source of much encouragement to all-rail shippers who are practically without competition from tidewater distributors. Small steam-users and retail dealers have in a great many cases worked off their surplus stocks that were accumulated last season, and now that high grade coals are to be had on short notice there is already a consistent demand from all parts of the territory. Many got into the habit of not buying, and yet the supplies of bituminous, even though mongrel in quality, have been gradually absorbed and stocks need replenishing. We look for an increasing demand of this character, as the outlook becomes more settled and definite.

Prices have already begun to reflect the change in conditions. Most of the quality grades are being held firmly at the recent Government figure, namely $2.95 per net ton f.o.b. mines in Central Pennsylvania. Occasionally this price is shaded to provide spot orders, but as a rule the operators are adhering to their policy of producing only what the market will absorb at what they consider to be a fair price. A few of the special grades are commanding higher levels, and it is one of the many indications that the market is resuming normal conditions that there is today almost an increasing differential between these and the inferior coals. The latter are druggy at prices not very much in excess of $2 per net ton, and without doubt buyers in New England are discriminating more than it has been their privilege to do for the past three years.

Progress has also been made in the tidewater situation. Just at the moment when New England industries were beginning to focus a widespread campaign to impress the Shipping Board with the great need of changing steamer rates on the coast the announcement was made, on Mar. 6, that effective that day all rates were withdrawn and that individual ship-owners and charterers were free to agree upon their own rates in the open market.

No activity in coals from Hampton Roads is expected in this market until June at the very earliest. Curtailments in manufacturing have considerably lengthened the period first estimated, and the railroads, too, because of extremely light traffic, are by no means using their normal tonnage of coal.

The only contracts being made today on the Southern coals are by producers who also own rehandling plants at tidewater for distribution inland. These are based upon $2.35 per net ton f.o.b. mines for Pocahontas, plus charges, and are being entered into by those who secured good service from the distributors last season and are convinced that Pocahontas, for instance, is worth a considerable differential over such Pennsylvania coals as are accessible all-rail and can be depended upon for regular deliveries.

Bituminous at wholesale is quoted about as follows, f.o.b. mines and at loading ports, per gross or net ton as designated:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.05@2.75	$2.80@3.20
Philadelphia, gross tons	4.15@4.90	5.00@5.45
New York, gross tons	4.50@5.25	5.35@5.80
Alongside Boston (water coal), gross tons	6.00@6.85	6.90@7.80

Georges Creek is quoted at present only f.o.b. mines for this territory—namely $3.20 per net ton—and its use is being confined to smithing purposes.

Pocahontas and New River are quoted at $4.70 @5.25 f.o.b. Norfolk and Newport News, Va., for spot coal, and $7.20 @ $8.60 alongside Boston, these prices being on a gross-ton basis.

Anthracite—The market for domestic sizes continues generally dull. Lower water rates from New York to points on Long Island Sound and to Boston have caused a scattering demand, however, since retail dealers feel that $1 freights to Providence and $1.25 to Boston may not continue indefinitely. There is no doubt about there being a surplus of tonnage and a great surplus of all the popular sizes at all the loading piers. In fact, it is stated that several of the larger companies have been embargoed because of their inability to move accumulations at the different New York loading ports.

Rail movement of domestic sizes has sloped off materially the past fortnight. Retail distributors know that any size or kind can be had on short notice, and there is also a disposition to wait until through tariffs are adjusted. There are many points in New England where coal originating on certain roads has the benefit of a differential that ranges from 30c.@50c. a ton. It is notable, however, that buyers have more confidence in prices and there seems to be a well-defined sentiment now that the present program attributed to the anthracite companies will carry through.

Current prices per gross ton f.o.b. New York loading ports rule as follows on company coal:

Egg	$7.80@7.95
Stove	7.95@8.15
Chestnut	8.05@8.35

NEW YORK

No change to be made in anthracite prices on Apr. 1. Ten cents per ton to be added for five months. Some tradesmen disappointed and retail dealers do not expect a large summer business. Demand continues slow. Buyers willing to take small cargoes to tide them over. Anthracite steam coals stronger. Better tone in bituminous situation and prices stronger. Tidewater surplus in good shape. Many inquiries regarding contracts.

Anthracite—The announcement that there would be no discount in the mine prices of the domestic sizes of anthracite on Apr. 1 was no surprise to the local trade, it having been anticipated for several weeks back that because of the high wages paid to the mine workers the operators would not make the usual April reduction of 50c. per ton. Accompanying the announcement was another that beginning May 1 prices would advance 10c. per ton for five months which means that on Sept. 1 prices for the domestic coals will be 50c. higher than they now are. It was reported that independent operators would add 15c. per ton for five months to their price.

Retail dealers are slowly cutting their stocks and some have come into the market for small cargoes of certain sizes to fill in the gaps. As an inducement to prevent an accumulation at the tidewater docks it is reported that shipments made early this month were made on the basis of prices to be quoted by the producers on Apr. 1. Even this opportunity to replenish their stocks failed to cause a heavy movement. Company product is being held firmly at full prices while bargain seekers have been able to pick up stray lots of so-called Independent coals at about 20c. below.

The slowing down of the washeries adds strength to the steam coal situation. These sizes are not so plentiful and prices are a trifle stronger. Prices at the mine ranged from $3 to $3.25 for buckwheat No. 1, $2 to $2.35 for rice, and $1.35 to $1.80 for barley, all of the better grades.

Dumpings of anthracite for the week ended Mar. 7 were 2414 cars, as compared with 2962 cars the week previous, a decrease of 546 cars.

Current quotations. White Ash, per gross tons, f.o.b. Tidewater, at the lower ports are as follows:

	Mine	Company Circular
Broken	$5.95	$7.80
Egg	5.85	7.70
Stove	6.10	7.95
Chestnut	6.20	8.05
Pea	4.80	6.55
Buckwheat	3.40	5.15
Rice	2.90	4.65
Barley	2.40	4.15

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates.

Bituminous—A better tone exists in the local market following the cleaning up of much of the surplus coal that was here a few weeks back. However, the situation is not entirely satisfactory. More of this loose coal must be got rid of before it will be safe for unsold product to be sent forward.

The Tidewater Coal Exchange reported that on Mar. 5 there were on hand at the New York docks 2715 cars of coal as compared with 6119 cars on Feb. 5. Precaution against a reoccurrence of an oversupply of coal at this tidewater was taken by the placing of embargoes against shipments as soon as the strike in the harbor was declared, with instructions that they be lifted as soon as the strike was off.

Consumers here are using their reserve stocks and the longer the demand remains slow the greater will the demand be when the reaction comes. There is no great urgency on the part of the wholesale dealers to dispose of their wares. They feel that consumers will soon come into the market of their own accord. A heavy demand is looked for when the reaction does set in, and this is likely to create higher prices.

Operators are not letting their coal go at low prices, just for the sake of keeping it on the move. Most coals are bringing substantial figures at the mine but are much easier at Tidewater based on the mine price. Coal in Pools Nos. 10 and 11 were heard quoted recently at from $2.30 to $2.50 on the mine price basis, while Pool No. 18 coals in loaded boats were quoted at from $3.65 to $3.95.

One bright feature is the resumption of inquiries for contract coals. Many more queries are now being received and prices based on twelve-month shipments have been quoted. In some instances these figures are practically the same as those quoted for spot coal at the mine, but in most instances show a substantial increase.

The report of dumpings at the local docks for seven days ending Mar. 7 show 4201 cars of bituminous coal dumped as against 5017 cars the week previous, a decrease of 796 cars.

The following are current quotations on the various grades of bituminous coals, at the mines, for spot delivery and contract:

	Spot	Contract
South Forks	$2.90 to $3.50	$3.10 to $3.50
Cambria County (good grades)	2.80 to 3.10	2.95 to 3.10
Clearfield County	2.65 to 2.95	.....
Reynoldsville	2.65 to 2.95	2.85 to 3.00
Quemahoning	2.85 to 3.10	2.95 to 3.10
Somerset County (best grades)	2.80 to 2.95	2.95 to 3.10
Somerset County (poorer grades)	2.50 to 2.75	2.75 to 2.95
Western Maryland	2.50 to 2.75	2.65 to 2.85
Fairmont	2.00 to 2.35	2.35 to 2.50
Latrobe	2.25 to 2.40	.....
Greensburg	2.35 to 2.40	.....
Westmoreland ¾-in.	2.60 to 2.75	2.65 to 2.75
Westmoreland run-of-mine	2.40 to 2.65	2.40 to 2.65

PHILADELPHIA

Anthracite spring price plan announced. Present circular to May 1. Ten cents increase each month to Sept. 1. Little increased buying. Prices vary. Some consumers show desire to put in spring coal, but dealers expect dull summer. Retailers think pea price a mistake. Price cutters reduce pea. Individuals have much coal on demurrage. Some contract inquiry. Bituminous in poor condition. Trifling contract business. Railroads buying on monthly basis.

Anthracite—On Mar. 6 one of the largest operating companies announced its price policy for the spring. While the plan as

decided upon was far from being a surprise, yet the early date of its announcement caused much comment. It was believed that any price announcement would be deferred until the last minute before Apr. 1. As announced the present circular prices will remain in effect until May 1, on which date 10c. per ton will be added to the present figures, increasing the same amount each month until Sept. 1, when the maximum increase of 50c. per ton will be reached and will continue in effect for the winter. The new schedule includes all of the sizes from broken to pea inclusive. Up to this time no action has been taken in regard to the steam sizes.

With the lead being taken by the big companies the smaller concerns naturally fell into line with practically the same terms as to prices. As a matter of fact many of the individual shippers had been trying to force sales for the past two weeks by offering to ship coal, guaranteeing to protect the dealer in the event that there should be a decline in April prices. In the case of one of the larger individual shippers announcement was made that they would increase their prices 15c. per ton for five months, which would bring their coal to a point 25c. a ton higher than the company shippers by Sept. 1. On the other hand, another indivldual shipper circularized the trade offering to ship egg and pea coal during this month and April at 20c. less than the present so-called circular prices. On stove and nut coal they still ask the full price.

Regret is expressed that the price of pea coal has not been revised, and it is held that even buckwheat should share in a downward revision. Pea never can sell at the present high rate and the operators realize it. The price is too near that of chestnut and cannot hold. Pea is at present stocked in greater quantities in the dealers' yards than any of the other family sizes. It has been the main point of attack by three or four notorious price cutters. This week saw its lowest level for many months when one firm turned its wagons into the streets displaying large signs announcing a reduction to $8 per ton. This is for 2240 lb. it must be remembered.

The individuals continue to be worried with coal standing on demurrage and the coal is being sacrificed. We have heard of sales being made in some instances at 30, 40 and 50c. off circular. Much depends on the conditions prevailing at the time and the reputation of the coal. Not a whisper is heard of any of the larger companies cutting prices.

There is some interest stirring in the contract situation, for the limited number of contracts made by the companies last year mostly expire on Apr. 1, and the consumers are making inquiry as to the price likely to be effective after Apr. 1. What few contracts were taken a year ago were with particularly large users, such as public service plants. This year, with a large surplus of all the sizes smaller than buckwheat accumulating, it would seem that contracting would become much more general. While the present spot price of buckwheat is $3.40, many individual shippers are known to have made sales at $2.75 and in between that figure. The gas companies using broken and egg coal are also coming into the market for the renewal of their contracts and some idea of the prices of these sizes can be obtained from the circular prices of these sizes just announced. It is believed that there will be considerable competition for the business on both the small steam sizes, as well as broken and egg.

The price per gross ton f. o. b. cars at mines for line shipment and f. o. b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$5.95	$7.30	Buckwheat	$3.40	$4.45
Egg	5.85	7.20	Rice	2.90	3.80
Stove	6.10	7.45	Boiler	2.70	3.70
Nut	6.20	7.55	Barley	2.40	3.30
Pea	4.80	6.05	Culm	1.25	2.15

Bituminous—There is not the least sign of a change in the bituminous market. Little coal is moving and as a consequence the business is far from profitable, with the mines working on a short schedule. While some of the larger companies have expressed a willingness to contract at a figure around $3.50, it can safely be said that there is only a slight tonnage likely to be closed at this price. The producers seem to have based this price on some profitable bunker business which they have been able to close. The railroads are buying their requirements on a monthly basis, asking for bids for each month's requirements.

BALTIMORE

Bituminous market poor; growing demand of spotty nature. Hard coal men await April and figure on plans for next coal year.

Bituminous—The soft coal market is poor, with each handler developing a quiet line of new inquiry. The call is for small lots for the most part, but the fact that there is a resumption of call, even in spotty form, from customers who have been out of the market for some time, is encouraging.

There is a determination on the part of the mine operators not to sell at a loss except when caught on some particular shipment. Thus it is that the quotations at the mines are for the most part much higher than some of the sales, mine basis, at tide. The irregular arrival of vessels here has added to the necessity at times of coal being sacrificed. The Shipping Board coal, too, had clogged the port and was forced out for all foreign bunker trade, but this is rapidly clearing now and leaving an open sale market. It is rather difficult to quote sales prices under the circumstances. Very best coals, except for one particular line that is held at $3.20, are selling for the most part around $2.75 to $3. Good coals, in fact excellent coals at times, are to be had at from $2.60 to $2.75. Poor to fair coals are running all the way from $2 to $2.50. Gas coals are below even the $2 mark here at tide under forced sales at times.

The trade is discussing the report that the entire Tidewater Exchange is to go out of business on Apr. 1. Such a plan, while possibly favored by a few big shippers, is hotly opposed by the majority of small handlers who say that the heavy demurrage charges and short free time allowed will not enable them to do business successfully except in some method of quick dumping and quick securing of coal for waiting bottoms. It is planned to urge some other plan for interchange of coal to prevent demurrage of ruinous nature should the Tidewater Exchange be ended.

Anthracite—Hard coal men are simply awaiting Apr. 1. No effort has been made to cut prices here to induce buying in the market where consumers are taking but small lots to tide over the balance of winter. The various reports in the trade of a spring schedule that will start off at the present price, with a 10c. increase per month after Apr. 1 is arousing much interest.

Lake Markets

PITTSBURGH

Market drags, but no weaker. Production 25 to 30 per cent. Steel industry revival in prospect.

The coal market has continued to drag, but there are no signs of increasing weakness on the part of operators. Production is running at 25 to 30 per cent. of capacity, and the continued curtailment is having a beneficial effect upon the situation. Stocks of coal have been reduced materially, despite the lower rate of consumption, and heavier requirements on the part of consumers are in near prospect.

Steel mill operations have deceased slightly in the past week, and are marked for heavier decreases in the next few weeks, as buying has been particularly light since it became generally believed that prices would have to decline. Secretary Redfield's plan for price deflation was unanimously adopted by trade representatives at a meeting in New York, and by Apr. 1 greatly reduced iron and steel prices will probably be in effect, stimulating buying and bringing about heavier mill operation. The steel producers will insist upon a wage reduction in connection with the reduced selling prices and it is possible they will propose that reductions be sought in the materials they buy, such as coal.

Demand for byproduct coal keeps up very well, as the byproduct coke ovens are operating almost full. Decrease in coke demand has fallen, and will in future fall, chiefly upon the beehive ovens.

Demand from retail dealers has continued poor, domestic consumption being light. Scarcely any coal has been used as a substitute for natural gas in the home the past winter, as the domestic gas supply has been practically adequate.

The market remains fairly firm at $2.25@2.35 for steam mine-run, with 1¼-in. domestic at but little more, and ¾-in. gas coal at $2.50@2.70 depending on grade, all per net ton at mine, Pittsburgh district.

BUFFALO

Not much improvement. Both anthracite and bituminous dragging. Some towns heavily loaded with coal.

Bituminous—The situation is about as unfavorable as ever. The supply of coal is still in excess of consumption. This is especially unfortunate, as it is now time to make spring contracts and nobody has much idea as to what prices will be.

The bituminous market is quite as steady as the light demand warrants, quotations remaining on the old Government basis of $4.65 for thin-vein Allegheny Valley, all sizes; $4.45 for Pittsburgh and No. 8 lump; $4.20 for some mine-run and slack; $5.65 for smithing and smokeless, $5.60 to $6.10 for cannel, all per net ton, f.o.b. Buffalo.

Anthracite—The only new feature of this branch of the trade is that the lake-shipping companies are taking tonnage quite liberally and already some cargoes have been loaded. There is no demand for the coal at upper-lake ports, but coal began to accumulate here so fast that something had to be done with it.

The demand is light. Some colder weather has set in lately, but the season is too far gone to be affected by a drop in temperature that cannot now last any length of time. The consumer is buying only from hand to mouth. Natural gas can again be used in furnaces on the 15th, and is preferred to coal generally.

Anthracite prices are as follows in the city:

	F.o.b. Cars, Gross Ton	At Curb, Net Ton
Grate	$8.55	$10.35
Egg	8.45	10.20
Stove	8.70	10.10
Chestnut	8.80	10.50
Pea	7.00	9.05
Buckwheat	5.70	7.75

An addition to the car prices of 25c. per ton is made on coal loaded into lake vessels.

CLEVELAND

Steam-coal users appear to have lost interest. Lake shippers looking for announcement restoring five days' free time on cars at Lake Erie ports, thus making possible abandonment of Great Lakes coal pool.

Bituminous—Contrasted with the slight impetus given the market last week by the interest shown by several large steam-coal users, the present lull—or rather the recurrence of the one that has abided for the last three months—seems all the more pronounced. The slight picking up all around last week proved a snare and a delusion. The "feelers" put out by several interests proved short-lived, even for "feelers," and virtually no buying has resulted.

The weather continues mild, and retail dealers cannot get away from the post. Many dealers are inclined to accept the present stagnant market as "part of the game," but are more pessimistic when figuring that the open winter will permit many consumers to start next winter with bins fairly well supplied. Pocahontas lump at $7.50 and mine-run at $7.20 are not proving alluring because of the weather.

Anthracite—Domestic consumers can now have all the egg they want at $10.85 and chestnut at $11.05, but the takers are few.

Quotations on coal in Cleveland in net tons, delivered, are as follows:

Anthracite:		Steam Coal:	
Egg	$10.85	No. 6 slack	4.60

Lake Trade—Nothing official has come out of Washington so far, but it is understood that the United States Railroad Administration will shortly amend demurrage rules so as to permit the abandonment of the Great Lakes pool and let lake shippers and upper dockmen get back to the old indivdual buying basis. Free time at Lake Erie ports now is limited to three days. Formerly it was five days, and before that seven days. It is felt that the five-day free time limit will be evoked again. This is the outstanding development in the lake trade since the close of last season, inasmuch as all concerned are anxious to forsake pooling.

DETROIT

Sales of bituminous coal in the Detroit market are still restricted by abnormally large stocks in the hands of buyers.

Bituminous—Demand for bituminous coal in the Detroit market falls far short of the volume of business handled at this season in preceding years. Jobbers and wholesalers report that it is a difficult task to interest buyers, though the high-grade coal they are now able to offer includes the product of several districts that could not be obtained in Detroit while the Government's zone regulations were in operation. The predicament of the retail dealers arouses sympathy of the jobbers and wholesalers. A large proportion of the retailers are holding heavy stocks of bituminous, bought in complying with recommendations of the fuel administration and with the expectation that the greater part of their customers would be unable to obtain other forms of fuel. The dropping of various restrictions made it possible for the customers to use coke and later obtain additional supplies of anthracite. Weather conditions, also, failed to stimulate demand and it is probable the dealers will have to carry heavy stocks through the summer.

The Government scale of prices is still being maintained on practically all the local business, the jobbers say, though it is admitted a few sales of slack have been made at a lower price to escape railroad demurrage.

Anthracite—The receipts of anthracite, though not of large volume, are said to be sufficient to provide for domestic requirements. Some of the dealers are reported to have made attempts to reduce delivery on orders previously given. There is also a plentiful supply of domestic coke.

COLUMBUS

The coal trade in Ohio continues rather quiet. More activity has developed in domestics as a result of lower temperatures. Steam business is still slow, but reports show that many consumers are cleaning up and will soon be in the market.

Little change has taken place in the Ohio coal trade during the past week. Buying is still limited to actual needs and there is no disposition to buy for the future. Purchasers are still playing a "waiting game" so to speak, and are only placing orders for current needs. The tone of the market is not good although some increased activity is noted in certain localities. There are a larger number of inquiries received showing a disposition on the part of purchasers to talk fuel.

The domestic trade is probably the most active. Colder weather which prevailed early in March caused a small spurt of buying on the part of retailers. Dealers stocks are not large and there is a general disposition to clean up. Demand for Pocahontas and other fancy grades is fairly good under the circumstances. Retail prices are generally well maintained and instances of cutting are rare. Dealers in northern Ohio and Michigan are fairly well stocked up and are not in the market to any extent. It is ascertained that the amount of coal that will be carried over by householders is not as large as was generally supposed. While the winter has been a mild one, coal consumption has been higher than was generally believed.

The steam business is quiet in every section. Larger consumers are cleaning up preparatory to the expiration on their contracts. Screenings are the weakest feature of the market. Railroads are now taking a larger tonnage as a result of recent orders of the Railroad Administration. These orders provided that a larger fuel tonnage must be purchased for current needs and reserve stocks shall not be depleted as rapidly as formerly.

LOUISVILLE

Weather conditions approximately the same, with demand for domestic and steam generally quiet. Conditions at mines showing no material change. River coal moving more freely.

The general tone of the coal trade is approximately the same as it has been, with domestic not quite so keen, probably, and at the same time just a slight shade of improvement in steam demand. Nothing much can be expected of domestic under such weather conditions, and steam cannot possibly improve materially until heavy industrial stocks are lowered.

River coal is again becoming a factor. The Pittsburgh Coal Co. last week received a ten-barge shipment from the West Virginia fields, this being the largest shipment to come in to one concern in many months. It is said to be the forerunner of heavy shipping later on. However, the river companies are taking full advantage of the rail rates, which does not make such coal profitable to many retailers.

From the best information available it would appear as though eastern Kentucky prices for the various fields are on a par level at the present time. These prices are as follows, per net ton:

	Eastern Kentucky	Western Kentucky
Block and egg	$2.85@3.00	$2.60
Mine-run	2.40@2.50	2.35
Nut and slack	2.00@2.10	2.05

These are fair prices, although there is some cutting being done. Some eastern Kentucky block and egg is selling at around $2.65, and some nut and slack at as low as $1.85 to $1.90; with some mine-run at $2.20.

Western Kentucky is striving to hold prices, as western Kentucky prices were already so low that coal could not be mined profitably at less per ton. However, eastern Kentucky in order to meet the competition on the lower grade western Kentucky has been cutting prices more or less.

BIRMINGHAM

Market conditions quiet, with little demand for steam fuel. Domestic trade has also eased up as result of warm weather. Prices remain stationary. Production curtailed 25 to 30 per cent.

The past week has not shown any improvement in trade conditions here, and steam coal is in slight demand. Cotton mills, brick plants and industries generally are either idle or operating on reduced schedules, and stock accumulations are keeping them out of the market. Railroads and other interests having contracts are not taking the maximum deliveries in many instances. There is a fair demand for blacksmith coal, which is not produced to any great extent by the mines in this district. Prices have not been affected by the soft trade conditions and are being maintained on basis of Government schedules for steam grades, quotations being as follows per net ton mines:

	Mine-Run	Prepared	Slack and Screenings
Big seam	$2.45	$2.75	$2.40
Black Creek and Cahaba	3.45	3.75	3.05
Jagger-Pratt Corona	2.85	3.05	2.45
Blacksmith	....	5.25	....

Domestic quotations, slightly increased, are as follows:

	Lump and Nut
Black Creek and Cahaba	$4.50
Corona	3.75
Jagger	3.50
Montvallo	5.00

Continued warm weather has caused a falling off in the demand for domestic grades, though there is ample business available to absorb the output of the mines at this time.

Coal production is lagging in about proportion to the requirements of the trade and is on a basis of 70 or 75 per cent. normal.

Coke

CONNELLSVILLE

March adjustments on contracts. Spot market lower.

Adjustments of prices for March shipment of furnace coke on contracts that call for periodic settlement of price when there is no Government price have practically all been made. One contract was adjusted at $4.50 for the month, but the usual settlement has been at $4.25. These settlements are not altogether conclusive as to market values, however, for two reasons. In the first place, contract coke is recognied as worth more than odd lots that are picked up in the open market as the operator renders service by shipping coke just as the furnace needs it and the quality is regular. On the other hand, some of the February adjustments proved unsatisfactory, the open market declining during the month more than had been expected when the settlements were made, and in a number of instances furnaces had something coming to them in the March adjustment, to equalize.

Operators holding contracts calling for "last Government price" have made no further adjustment. In the majority of cases a voluntary adjustment was made to $5, the Government price having been $6, but some contracts have thus far not been adjusted at all. Operators who made the $5 adjustment are hoping that pig iron prices will be reduced so that demand may be stimulated and coke consumption increased.

The spot and prompt market has declined farther. Several fair-sized lots of furnace coke for March shipment have been offered at $4, and odd lots for spot shipment are easily picked up at this figure in the few cases in which they are needed, while $4.25 appears to be the highest price that is seriously quoted. So much more 72-hour coke is made, especially with the present four-day and five day operations, than is needed by the foundries that some operators are offering foundry coke at $4.50 or possibly at less. One or two established operators making a specialty of foundry coke are still adhering to $6 as they have contracts to protect and are not interested in the small lots they could sell by cutting prices. The market for spot and prompt coke is quotable as follows: Furnace, $4@4.25; foundry, $4.50@6, per net ton at ovens.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Mar. 1 at 224,872 tons, a decrease of 8740 tons.

Middle Western

GENERAL REVIEW

Better feeling in Middle West due to an improvement in market conditions. Peculiar situation in Iowa.

During the past week there has been an improvement in market conditions. This change for the better is noticeable, although it is not much to brag about. The demand for both steam and domestic coals has been better since Mar. 1 than at any time since the beginning of this year. Briefly, the reasons for this slight strengthening of the market are—first, the weather has been cold, and considerable domestic coal has moved as a consequence; second, storage piles are being rapidly depleted, and buyers have come to the conclusion that it is a wise plan to have plenty of coal on hand during these times of labor unrest; third, the contract season is upon us, and some trial coal is being shipped. It is believed that the market will improve a little from now on, although it will take a tremendous amount of improvement to put the market back into anything resembling a satisfactory condition.

Contrary to prevailing opinions outside of the coal industry, prices are firm, with no signs of weakening, so far as good coal is concerned. The buying public has adapted itself to the new and advanced prices, effective Feb. 1, for coal from southern Illinois, and the fourth vein Indiana fields. It is expected that other coal fields in the Middle West, now marketing their product on the basis of the late Government prices, will raise their prices. These increases are logical, and to be expected. The selling prices set by the Government allowed only a small margin of profit on full running time, and with conditions as at present, with mines operating at from 30 to 50 per cent. capacity, the operators cannot hope to break even unless they charge more for their coal. So far as the buying public is concerned, it is becoming more and more suspicious of bargains in coal. When an operator or jobber, during these times, is forced to sell his coal below cost, there is a reason for it; and that reason is—the coal is usually off grade.

Taking the coal operators as a unit, they are all confronted at this time with the same problem. That problem is, what shall they do with their steam sizes or screenings? Manufacturing today is at a low ebb. The mines, therefore, have little demand for steam coals. The competition for steam business is consequently keen, and there is a natural tendency toward price cutting. To overcome this, some of the operators' associations are talking of storing coal for themselves, rather than selling their product to a factory at a less price and allow others to store the coal and make a profit. The operators figure that it will be but a short time before the country will absorb all the steam coal available.

Some progress is being made on the railroad fuel question, and the operators in this territory are more than pleased over the progress made at Washington by the Railroad Fuel Committee of the National Coal Operators' Association. It is generally felt that this question, so long a thorn in the side of the industry, will soon be settled on a basis fair to all.

Eastern coal is moving more freely into this territory. Iowa and South Dakota seem to be ordering the most liberally, with northern Illinois a close third. A rather curious situation has developed in Iowa. During the war but little Eastern coal reached Iowa, but that state was given the highest grade products from Illinois to replace the temporarily absent southeastern Kentucky block, Pocahontas and West Virginia splint. Besides Illinois coal, Iowa consumed a large tonnage of coal mined within her own borders. The native fuel was used for the cheap domestic trade and for steam purposes. The Illinois coal was utilized by the trade, both steam and domestic, who wanted the best to be had. The native coals have a low freight rate, while the fuel imported from Illinois has a comparatively heavy rate. Men closely in touch with trade conditions freely predict that Iowa, from now on, will purchase its cheap coal from its own mines, and its high-grade fuels from Kentucky and West Virginia. To sum up the situation, if Iowa wants cheap coal, it will use the most inexpensive it can get—namely, its own—and if it wants expensive coal, it will draw on the highest grade fields of the East.

While it is admitted the situation in the Middle West is a little better, it is due to national conditions, and not the individual efforts of coal companies, who have covered the territory with salesmen and advertising matter.

CHICAGO

Little signs of activity. Cold weather helps domestic trade, but has no effect on steam business.

Conditions in this city are not so favorable to the coal industry as at other points throughout the Middle West. There are no signs of renewed industrial activity. On the contrary, factories are closing down, or running from two to three days per week. The weather has been cold, with a good snow storm, but this has only served to help out the domestic trade, having little or no effect on steam business. As is true with the rest of this Middle West territory, Chicago is ordering out more eastern coal than heretofore. This undoubtedly is because the various retail dealers throughout the city have succeeded in reducing the storage coal they have on hand.

Current prices per ton for Illinois and Indiana coal are as follows:

ILLINOIS

	F.o.b. Mines	Rate to Chicago
Southern Illinois		
Franklin, Saline and Williamson Counties,		
Prepared sizes	$2.75	$1.55
Mine-run	2.35 @ $2.50	1.55
Screenings	2.05	1.55
Central Illinois		
Springfield District		
Prepared sizes	2.55 @ 2.75	1.32
Mine-run	2.35	1.32
Screenings	2.05	1.32
Northern Illinois		
Prepared sizes	3.25	1.24
Mine-run	3.00	1.24
Screenings	2.75	1.24

INDIANA

Clinton 4th Vein District		
Prepared sizes	2.55 @ 2.75	1.27
Mine-run	2.35	1.27
Screenings	2.05	1.27
Knox County Field		
Prepared sizes	2.55 @ 2.75	1.37
Mine-run	2.35	1.37
Screenings	2.05	1.37

MILWAUKEE

Little improvement in the coal situation so far as demand is concerned. Prices still maintained, however.

The coal market continues dull and uninteresting. The demand is light all around and stocks are not dwindling to any great extent. The interior country is fairly well off in supplies, because of the mild weather. It is estimated that the wood-burning campaign of last fall saved 20,000 tons of coal on farms and in schoolhouses. Prices are well maintained as yet, nothwithstanding reports of cutting by western producers.

Milwaukee city authorities have decided to make a test of Illinois and eastern coal before letting contracts for the fuel supply for the various city institutions. Last year the bids of western producers were turned down, notwithstanding the same were $31,832 lower than the offers submitted by the dock companies. The action was taken mainly because of the uncertainty of rail transportation. The efficiency of western coal since tried out at one water station was 12 per cent. greater than that of eastern coal. On this basis Mayor Hoan declares the city was a loser to the extent of $62,172 by discarding the bids of Illinois operators last year.

Following are the coal prices at Milwaukee, per short ton, effective Mar. 1. The prices given include delivery. At the yards the prices are 50c. per ton less:

Domestic

Anthracite—	Short Ton
Egg	$12.20
Stove	12.40
Nut	12.50
Pea	11.00
Buckwheat	10.60
Bituminous—	
Pocahontas mine-run	$8.15
Hocking, screened	7.90
Youghiogheny, screened	7.90
Pittsburgh, No. 8, screened	7.90
West Virginia, screened	8.40
Splint, screened	8.40
Kentucky, screened	8.40
Illinois, screened	7.25
Coke—	
Solvay, large sizes	$11.50
Solvay, small sizes	10.25
Smithing	8.40
Steam—	
Youghiogheny, Hocking and Pittsburgh	
No. 8, screened	$7.18
No. 8, pile run	6.93
No. 8 screenings	6.68
West Virginia, Kentucky and splint	
Screened	7.68
Pile run	7.43
Screenings	7.18
Illinois and Indiana, screened	6.50
Pile run	6.25
Screenings	6.00
Smithing	7.68

ST. LOUIS

Warm weather continues, with no market for either steam or domestic. Standard coal going at below cost and demoralized conditions prevail in all fields, with nothing optimistic to look forward to at present. Country business slow. Light demand for anthracite and smokeless, and coke is heavy.

There is no demand for any kind of coal locally except in small quantities. The domestic tonnage is extremely light and this condition is not only representative of St. Louis proper, but is general throughout this section of the country. This has kept the dealers from laying in any large stocks.

With coal that continues to go down in price and rumors of the situation in the Fifth and Ninth districts, the steam trade on Standard coals will not lay in any supply and only buys from day to day.

The tonnage of steam coal, however, is light. Storage piles continue to be cleaned up and the manufacturing industries in a general way throughout the Mississippi Valley are below normal in their coal requirements.

Locally, the demand in a domestic way for anthracite is extremely light. The dealers have good supplies on hand. There is some dissatisfaction over the high prices and the poor preparation and quality.

There is a little smokeless from West Virginia coming in, but the demand is easy on this and dealers are going to go slow on storage supplies. Gas house and byproduct coke is heavy. The price seems too high, for the public buying is light and in small quantities only.

Operating conditions in the Fifth and Ninth districts are at low ebb. The mines that work for the most part are selling below the cost of production. There is considerable dissatisfaction among the miners on account of not being able to get sufficient working time to make actual living expenses. Many of these have bought Liberty Bonds and are being pushed for payments.

Screenings keep many of the mines from working and some of these plants have screenings on hand as long as four and five weeks. Nut sizes are also heavy, and the lump is not moving any too well. Car supply is good and transportation fair. Prices on all Standard coals are below the Government price.

In the Mt. Olive field working conditions are not all that could be desired, but the price is being maintained in a general way. There was a cut made by the Consolidated Coal Co. on local shipments to $2.30 on domestic sizes. This is the first break in price in this field. A fairly good tonnage of this coal is moving north and west, but steam sizes are heavy.

The railroad tonnage out of both the Standard and Mt. Olive fields seems to become lighter, but it helps considerably even at that.

In the Carterville field of Williamson and Franklin Counties, as well as in the Du Quoin field, steam sizes from No. 1 nut down are piling up on the tracks with no place to move them. At some mines even lump and egg are slow, and in a general way the market is not available for the tonnage from these fields. The mines, however, for the most part are getting from three to five days a week and conditions are more satisfactory in these fields than in other sections of the state. Car supply and transportation are good. There is no great dissatisfaction among the miners in these fields, but there is an oversupply of labor.

The prevailing circular per net ton f.o.b. mines is as follows:

Franklin County	Mt. Olive and Staunton	Standard
Prepared sizes, lump, egg, Nos. 1 and 2 nut	$2.75	.....
Williamson County		
Prepared sizes, lump, egg, nut	$2.55	$2.55
Mine-run	2.20	2.20
Screenings	2.05	2.05
3-in. lump	....	2.30
2-in. lump	....	....

	$1.90@2.25
	1.60@1.70
	.95@1.10
	.....
	1.75@1.90

Williamson-Franklin rate to St. Louis is $1.10; other rates 92½c.

FREIGHT RATES—On finished steel products in the Pittsburgh district including plates, structural shapes, merchant steel, bars, pipe fittings, plain and galvanized wire nails, rivets, spikes, bolts, flat sheets (except planished), chains, etc., the following freight rates per 100 lb. are effective:

Boston	$0.30	New Orleans	$0.38½
Buffalo	.17	New York	.27
Chicago	.27	Philadelphia	.24½
Cincinnati	.23	St. Louis	.24
Cleveland	.17	St. Paul	.49½
Denver	.99	Pacific Coast (all rail)	1.25
Kansas City	.59		

Note—Add 3% transportation tax. *Minimum carload, 80,000 lb.

COAL AGE

Volume 15 New York, March 20, 1919 Number 12

Health and Industry

By Floyd W. Parsons

MINE officials in many localities are having a little rest from the strenuous war days of last year. This affords them an opportunity to analyze their industrial situation and lay plans to improve conditions and eliminate danger spots.

There are other matters of importance besides prices, wages and markets, and one of the things that might be studied with profit right now is the question of health as it relates to industry. The degree of health that employees enjoy determines largely their degree of happiness, contentment and efficiency.

No other machine compares with the human machine in industrial importance, and yet the average corporation manager is often more concerned about the grade of oil that is fed into the company's mechanical equipment than he is about the quality of the water that the employees drink.

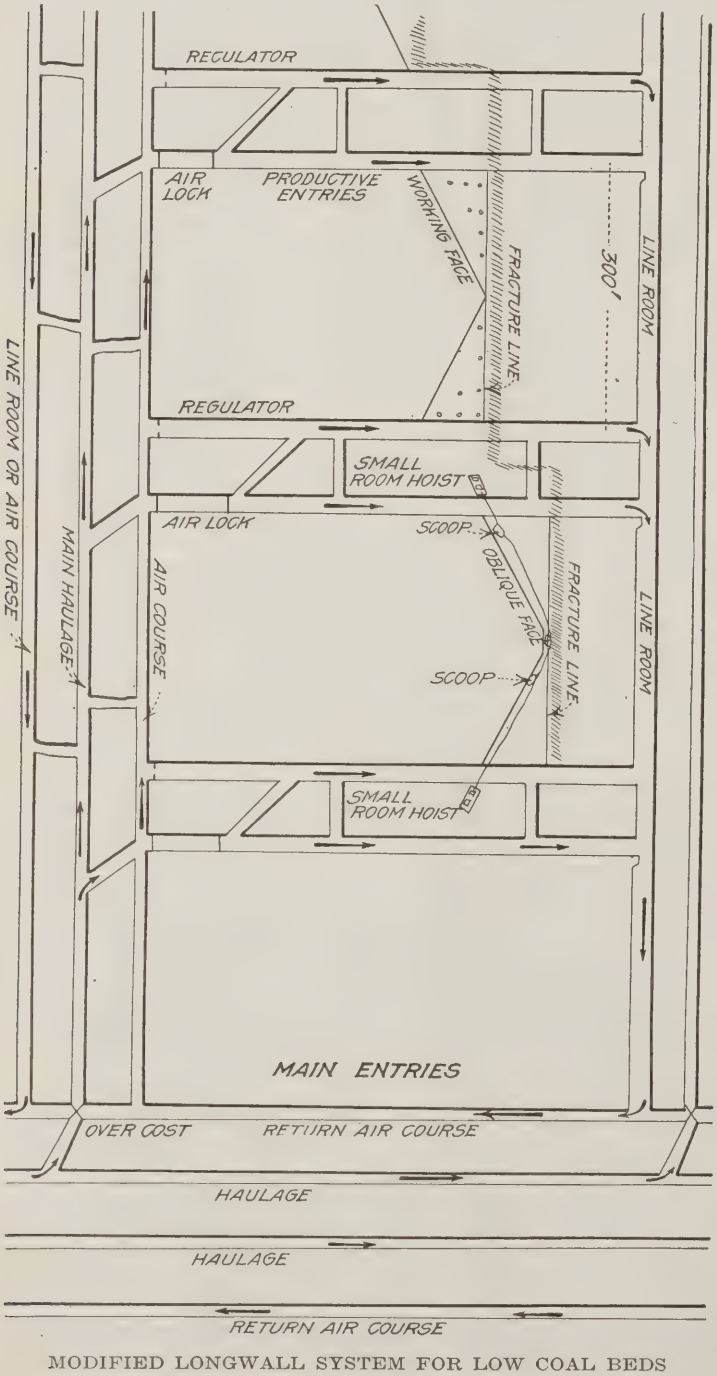
No company should approach the problem of maintaining and improving the workman's health in a spirit of philanthropy. It should be viewed purely as a matter of good business, not of kindness. Company officials may use their corporation's funds to increase operating efficiency, but not to engage in acts of benevolence. Furthermore, workmen are resentful and suspicious of plans that appear to be based on charity.

Careful investigations show that the time lost by workmen through illness is far greater than that lost as the result of industrial accidents. Some day the money losses to employees from sickness will have to be borne by the employer or the state in the same way that losses through accidents are now borne. Workmen's compensation was originally established to insure the individual against losses he is unable to bear, and it is only a matter of time until other misfortunes than accidents will be included in the list of things for which compensation shall be paid.

During the war there was a serious let-up in safety and welfare work on the part of many corporations, due to the urgent demand for increased production. In the mining industry, as well as in other fields, the various companies have been rather slow in getting back on a pre-war basis. This situation is regrettable because of the fact that professional trouble makers are now taking advantage of every opportunity to point out the weak spots in our present industrial system. No time should be lost and no effort spared to bring first-aid and welfare work back to a pre-war basis of efficiency.

Not only is this desirable, but company officials should not stop there. The time has arrived when the successful manager should make a study of human physiology and endeavor to find ways whereby such knowledge may be applied to working conditions in and around the mines. Ninety per cent. of the problems of health have to do with matters of prevention, while 99 per cent. of the Nation's doctors devote themselves, not to prevention, but to curing the ills of mankind. One company employing several thousand men has seen the light of coming events and has established a system whereby the chief efforts of the company's doctors are devoted to keeping the employees in good health. When sickness does result to one of this company's workmen, or to any member of his family, the company foots the bill. Over a period of a year the cost of the plan to this corporation was a little less than $12 per workman, or about 4c. per day per man.

Other investigators are now getting facts concerning the cost to their company of various deficiencies, such as a poor water supply, unsanitary surroundings, inadequate washing facilities, poor ventilation, insufficient drainage and sewage, and dozens of other conditions tending to affect, not only the health, but the moral well-being of the men and their families. It is doubtful if any class of work that a mining company could do would show better results in the way of reducing operating costs than a properly conducted campaign designed to encourage the observance of strict personal hygiene on the part of employees. The average workman has very little idea of what may be termed a balanced diet on which he can do his work with greatest efficiency and least effort. An investigation of the dinner pails of employees at a southern mine showed an astonishing situation. Not one man in ten had in his bucket the proper rations on which to base a maximum physical effort.



This matter of health right now is of such vital importance that this first page in Coal Age will be devoted to a discussion of the subject for several weeks to come. Above all things, at the present moment, we need sound minds, and these we cannot have unless first we have sound bodies. Contentment and health grow on the same tree. Ill-health and unrest are fruits of another vine.

IDEAS AND SUGGESTIONS

Longwall System for Low Coal Seams

By Charles Martin
Seward, Penn.

The accompanying illustration shows a modified longwall system for working low coal beds that I would like to submit to the readers of *Coal Age* for criticism. This proposed method, as shown on the drawing, permits the use of all machinery formerly employed in the room-and-pillar method and does away with any extra expense for new equipment. There is no big, heavy, cumbersome machinery to be moved in following up the face, and little or no expense will be connected with its installation as compared to the present systems. I feel satisfied that quite a large tonnage could be handled by a few men.

MODIFIED LONGWALL SYSTEM FOR LOW COAL BEDS

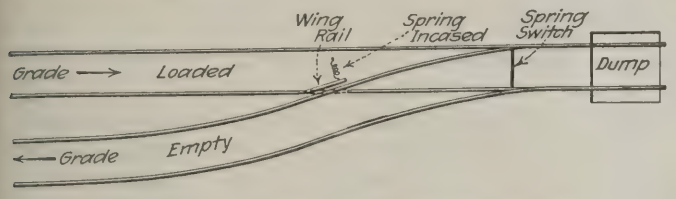
One of the advantages I think this system possesses over the old methods is the oblique face, which gives protection to the workmen and machinery and keeps the line of fracture behind the active face. Another big advantage is high recovery, as with this method I can see no reason for losing any coal. Furthermore, it eliminates to a considerable extent the possibility of a squeeze or creep.

I would like to hear from some one who has had experience with some of the late methods of longwall or the new methods where scoops are used.

The following is a description of how this system works out in theory: The productive entries are driven practically the same as in room-and-pillar working except that both headings are driven as haulageways, having either the bottom or top taken to give the required height. These can be driven on any centers suitable to conditions. I have shown these on the drawing as being 300 ft. apart, which gives little better than a 150-ft. face on either side of the fracture line. Then by using two small room hoists, one on each heading, as shown, and two scoops of about one-ton capacity, these can work in conjunction in moving the coal down to the loading platform, working alternately back and forth. Practically any of the late type shortwall mining machines used in the room-and-pillar system can be adapted to this system to good advantage, by either cutting clear across the face (and when this is cleaned up reverse the bits and cut back across the face) or using two machines, one on either side.

The main entries can be driven on either the three, four or five-entry system, according to the size of the field.

A Spring-Operated Frog



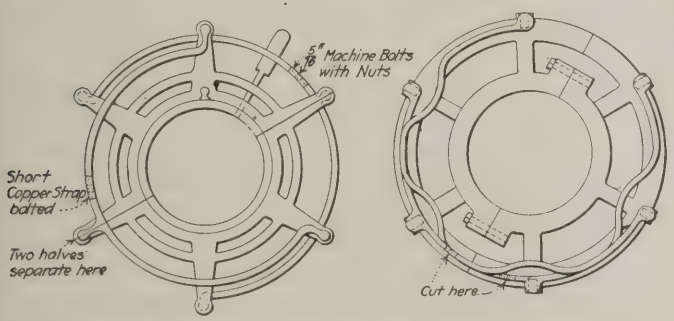
By H. C. Cockill
Jacob, Penn.

While a crossover dump is no doubt economical and satisfactory where a large output is obtainable, we sometimes run across an "old-fashioned dump" where the dumper is required to pull the empty car back up the grade until after it passes the frog on the loaded track. This is a hard and laborious process where only one man has the task to perform.

In order to do away with this tiresome operation the company with which I am connected has installed on the tipple at its Jacob mine the spring frog shown in the accompanying illustration. The wing rail shown is about 4 ft. long. The spring may well be a heavy door spring. The loaded cars, after leaving the scales, come down the grade, throwing the wing rail against

the action of the spring in line with the rail or the loaded track. This springs back into the position shown in the diagram immediately after the loaded car passes over it on its way to the dump.

After the car is emptied of its contents the dump, if properly balanced, will come back to its original



SPRING-OPERATED FROG INSTALLATION

position. The resulting jar will give the car a start which, with a slight pull on the part of the dumper, moves the car through the spring switch close to the dump and thence down the grade of the empty track. The diagram shows how easily the empty track can be placed at a lower level than the loaded track when the frog trouble has been eliminated. The spring should be planked over to avoid damage. This spring frog has been in use for the past three years and has been found quite satisfactory.

Disconnecting Generator Brush Yokes

By J. J. Nolan
Linton, Ind.

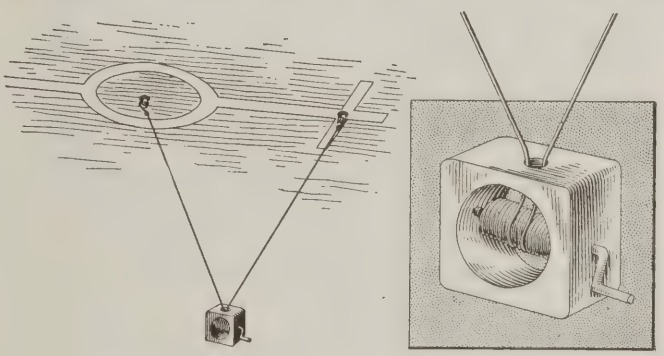
No doubt many readers will recognize in the accompanying illustration the two brush yokes used on two old types of generators frequently seen in mining plants even yet, and usually doing good service too. Those having charge of them possibly have had occasion at some time or another to dismantle the yoke and brush holder arrangement for such a cause as the bearing getting hot, burned out, or worn out, or perhaps to repair or turn up the commutator. We will assume that previous to this time the machine had been giving no trouble from poor commutation or other cause and required little attention, and that after reassembling

BRUSH YOKES USED ON OLD GENERATORS

with care and precaution, it did not give as good results as formerly. The firm with which I am connected has several of these types to care for and has had occasion to dismantle them for the reasons above enumerated. The drawings show how, by proper care, a considerable amount of work and worry may be avoided.

The cutting of the copper bar connector does not necessarily need to be done until occasion requires this yoke to be taken off for some cause. Then with a hacksaw cut each one through as shown, then take the piece to the drill press and bore the holes shown. A breast drill will do the work just as well.

It will be observed in the left hand figure that only two brush holders are disturbed, these being the two in the joint where the yoke separates, while in the right-hand figure none is disturbed.



The whole operation of dismantling and reassembling can be done in this way in a short time, while with the old method when one is compelled to hurry through the job on account of the generator being needed proper attention is probably not given to care in spacing and fitting the brushes and holders. This often results in the holders getting misplaced owing to confusing marks. Each brush must then be sanded to fit.

In many instances the proper attention and care is not taken in spacing and adjusting all holders the same distance from the commutator. The proper space between brush holder and commutator should not be over $\frac{1}{8}$ to $\frac{5}{32}$ inch.

Homemade Double String Plumb Bob

By C. W. Stafford
Stone, Ky.

The illustration below shows a homemade double string plumb bob which supplies a long-felt want among mine foremen and their assistants. The particularly attractive features of its construction are its concentrated weight (being made of lead) and the fact that the two strings are wound upon the spindle inside the

DETAILS OF AN EASILY MADE PLUMB BOB

block. They are thus not liable to get tangled up among themselves or with the other plunder in a man's pocket. This device is alweays ready for use and certainly beats the piece of rock or spike used by many. It can be made in any mine shop in a few minutes. So far as I know, the first one was made by Mine Foreman Tom Mitchel, of Hardy, Kentucky.

Incombustible Matter in Mine Air

The old method of computing the amount of incombustible matter in the air of coal mines and quarries was to proceed by analysis, arriving at differences after evaporating moisture and burning what could be burned. In 1912, J. Taffanel introduced his volumetric system, recently severely tested by the Bureau of Mines.

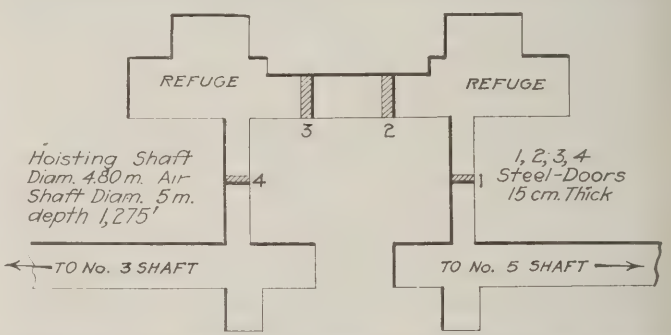
The Taffanel volumeter as constructed was found wanting in accuracy. But by enlarging the diameter of the tube and lengthening it by 20 per cent. it was possible to increase the weight to be tested to 20 grams, twice the former quantity. This gave excellent results.

The Mines of Bruay, France

By Gaston Libiez
Peru, Illinois

SYNOPSIS — *The deep shafts tap several coal beds of varying thickness. The thinner measures are worked longwall, while the thicker ones are worked in panels. Hydraulic flushing is practiced with considerable success.*

AT THE present time a few words about the French collieries located at Bruay, Pas-de-Calais, 30 km. (18½ mi.) northwest of Lens, the great mining center, and 12 km. (7½ mi.) southwest of Bethune, the seat of large mining developments, will be of interest. The mining company operating at Bruay has several large up-to-date mines, as may be seen from the accompanying illustrations. I will give some explanation of the working methods employed at the No. 3 shaft, as I feel sure it will interest many readers.



The No. 3 shaft is 1275 ft. deep, eleven beds are worked, the first one being reached at 839 ft. The beds pitch about 7 deg., the largest bed being about 12 ft. thick. The longwall system of mining prevails in the small beds, but the larger ones are worked by the panel retreating system. The gob is filled by flushing with culm or a mixture of water and sand as soon as the pillars are removed.

From the main shaft a main gangway is driven on both sides along the strike until the boundary is reached. Inclines are driven on the rise to meet another gangway starting from the first incline. This gangway is used as the main return when both roads have reached the property limits. It contains a pipe line for hydraulic filling and also telephone lines. Additional inclines are only started in retreating, when the removal of pillars tributary to the last or farther one is well under way. These are spaced 60 m. (197 ft.) apart. From these inclines roads are turned toward the workings at 15 m. (49 ft.) center to center.

The removal of pillars is accomplished by taking steps 5 m. (16.4 ft.) wide with a little airway well timbered alongside on the rise. The pillar being 15 m. (49 ft.) long measured on the pitch, there are 75 sq.m. (90 sq.yd.) to be filled at the start. Next the passageway timbers are removed, while the next pillar or step is taken out and the timbers used again.

The filling material is brought by pipes 130 mm. (5 in.) in diameter and arranged at the head of the place to be filled in two branches with a valve between to control the flow in either branch. This arrangement facilitates the flushing and work is not unnecessarily stopped.

About 2000 hectoliters (261 cu.yd.) of material are stowed per hour. Along the passageway props and timbers are strongly set to resist pressure, and plank or boards 10 to 15 cm. (1½ to 4 in.) wide by 1.5 to 2 cm. (⅜ to ½ in.) thick are nailed to their bases. Upon these boards a piece of canvas 1 m. to 1.5 m. (3 ft. 3½ in. to 4 ft. 7½ in.) wide is nailed from one road to the other. Additional boards are nailed in place above to keep the first roll of canvas taut; another roll is then nailed above the first, and so on to the full height of the workings. The canvas is loosely woven and full of small holes, thus permitting the excess water to gravitate and relieve pressure. Men employed at this bratticing keep striking lightly along the brattice to assist water in flowing out. The water returns to the sump, where it is pumped out again.

REFUGE CHAMBERS IN PASSAGE CONNECTING MINES

The bottom of the main shaft is provided with a sump about 30 ft. deep. A little below the level of the bottom a ditch 1200 m. (3940 ft.) long by 1.80 x 2 m. (7 x 8 ft.) is driven in solid rock to accommodate the excess water in its return from the workings. A small pump or a siphon draws the water from local sumps into this road.

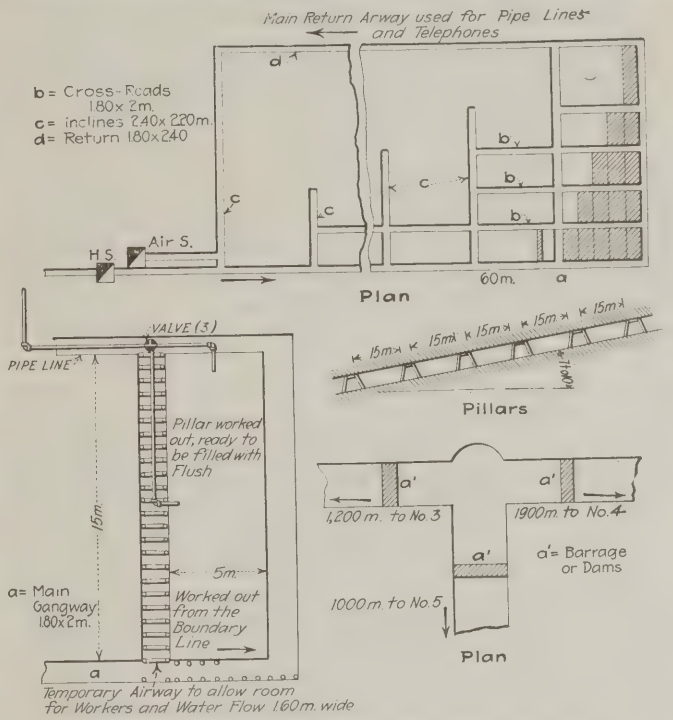
All this water is handled by a powerful centrifugal pump and discharged on the surface into a large reservoir, to be used anew. The pump discharge is about 3.35 m. (985 gal.) per minute against a head of 360 m. (1180 ft.). It is driven by an electric motor operating at 5000 volts, 44 amp. and 1500 r.p.m. Culm banks from nearby coke ovens belonging to another company were bought at transportation cost. The present system has been in use for the past 15 years. Sand and gravel coming from the seashore is also employed as a stowage material.

VIEWS OF MINES NOS. 1, 3 AND 6 AT BRUAY, PAS-DE-CALAIS, FRANCE

In the mining at and near the boundary, ventilation is secured mainly with compressed air. The main pipes are 150 mm. (6 in.) in diameter. These are decreased to 100 mm. (4 in.) in diameter at the boundary of each district. On the cross roads or close to the working places pipes 70 and 50 mm. (3¾ and 2 in.) in diameter are taken off for drilling machines and punchers, while 30-mm. (1⅛-in.) pipes are used for small ventilators or blowers necessary to ventilation. When driving an incline or a main gangway, large tubes are used to convey the air. They are connected in lengths of 2 m. (6½ ft.), the joints being well calked to avoid short-circuiting of air. At the mouth of each entry or road a connection is made from a supply pipe of 30 mm. (1⅛ in.) in diameter and a nozzle arranged to produce an injector effect. A valve is placed at each of such connections.

On tunnel work a small fan is used to advantage. But little gas is encountered. However, where small quantities are given off or fear of meeting gas is entertained, a more powerful fan is used in connection with tubes at least 50 ct. (2 in.) in diameter.

Punchers are used to undercut and shear the coal, and permissible explosives are used to bring it down. Where shooting is done the bottom of working places is covered with fine clay or lime 1 in. thick, to cover and neutralize the coal dust. Also at the mouth of a hole or in its immediate proximity a piece of thin sheet steel is suspended in order to receive the first blow of the shot. This sheet measures 1 m. x 80 cm. (3 ft. 3 in. x 2 ft. 7 in.). It is claimed that this scheme gives good results. As a further precaution against dust explosions boards loaded with pulverized cinders are hung 30 ct. (1⅛ in.) center to center between the timber sets by iron rods and so arranged as to upset at the shock of a light explosion.



It is a law in France that all underground workings be connected, and as a precaution the company has developed a scheme to prevent an explosion from propagating into the next workings. When the two roads to be connected are close to each other a narrow passage is turned at right angles and driven 90 ct. (35 in.) wide and 5 m. (19½ ft.) long; when this distance is reached, another right-angle turn is made and a passageway the same dimensions as the former is again started to meet the other connection from the other shaft. The height of these passes is 2.50 m. (8 ft. 3 in.). Four doors of steel 6 in. thick are put in place, opening against each other. At the four corners wide rooms are excavated as refuge places. All this work is heavily reinforced with concrete.

Connection with the drainage ditches for water is also made between the shafts. These meet at a common point where any one of them can be closed by a suitable dam so that either may be cleaned out. The three shafts connected have ditches 1200, 1900 and 1000 m. (3940, 6250 and 3280 ft.) long respectively. The dams or barrages shown on the drawing are operative only when needed for cleaning.

The operation here described has an output of 3000 to 3700 cars daily. These cars contains eight hectoliters (28¼ cu.ft.) and are not topped. The cages hold eight cars. The number of men employed is about 1000, of which number 300 are on the night shift. There are 26 bosses for both shifts under a mining engineer.

It is needless to say that only safety lamps are in use. An explosion occurred in a mine located only few miles away that impressed upon everyone the advisability of using these lamps. This happened in 1912, if I remember rightly. A fire started in a certain coal bed and was well smothered. But I think that the stoppings were not properly made as a disastrous explosion occurred as the result.

The Bruay mines have suffered from the shelling of the Germans. The whole town was evacuated when the enemy drove toward the coast last spring. Many homes were wrecked and the people had to wear gas

DETAILS OF THE METHODS OF WORKING

masks day and night for months. The miners have worked nine hours a day during the war.

I am much pleased to read Arthur J. Baldwin's statement in *Coal Age* that "it will be a worth while result if ancient practices are abandoned and mining machines introduced." Indeed there are many coal beds in France that I believe could be worked successfully with coal cutters, as in driving roads to the property limits and in drawing pillars.

As the result of the Lens devastation one can readily believe that Bruay has been crowded for the past 4 years. In peace time the population is well over 18,000 inhabitants, all miners. Thank God that these mines are saved to France intact!

In the event of a mine disaster provision must necessarily be made for receiving the bodies of those killed or preparing the bodies for burial. The improvised morgue should be within a building that is well ventilated and has good drainage facilities. Men may be found alive within the mines, severely burned or so injured as to requre hospital treatment, and a building should be selected that can be readily used as a hospital. In the selection of the morgue and the hospital the advice of the local surgeon or physician and undertaker should be sought.—*Rescue and Recovery Operations in Mines.*

Details of Important Mining Bill Before the British Columbia Legislature

By Robert Dunn
Victoria, B. C.

SYNOPSIS—*An important bill is before the British Columbia Legislature proposing many changes of statute affecting mines. Among the more important of these are provisions concerning miners' examinations, the treatment of hoisting ropes and the practical elimination of all but safety lamps for miners' use.*

REGULATIONS of great importance to the coal-mining industry of the province have been laid before the British Columbia Legislature by the Hon. William Sloan, minister of mines, in a bill entitled "An Act to Amend the Coal Mines Regulation Act." These will radically change for the better the present system of conducting examinations for first, second and third class coal-mining certificates, removing much of the present superfluous administrative machinery by placing the new widely distributed authority in the hands of one competent and responsible board of examiners. These regulations apply also to the existing methods of examining and issuing certificates of competency to coal miners. It is proposed that one traveling board of examiners shall have charge of this important work, the duties of which shall be to go from colliery to colliery throughout the province for the purpose of passing upon the proficiency of coal miners applying for certificates.

Various other changes are provided for, having in view making the mines safer and removing, as far as possible, the chief dangers with which the underground workers have to contend. In some of the latter legislation British Columbia is setting the pace for America, notably in respect of the proposal that all wire cables shall be given hot oil baths at regular intervals and in a provision which, in its application, will practically eliminate all but safety lamps in underground coal workings.

Would Appoint a Minimum Wage Board

The initial provision of the bill is under the subtitle "Constitution of Coal Miners' Minimum Wage Board." The text of this section is clear in itself. The board is to consist of the chief inspector of mines as chairman and "two other members to be appointed by the minister, one of whom shall be appointed to represent the mine owners and one to represent the coal miners." The duties of this board shall be to "define and redefine any portion of the province as a minimum wage district for the purposes of this section; to impose conditions and exceptions to which the application of the minimum wage in any district shall be subject; and to regulate the time and manner of giving notice of the sittings of the board and the conduct of business thereat."

Having fixed a district to which a minimum wage shall apply its duty, naturally, shall be to decide what the minimum wage, within the bounds of the area, shall be, proper consideration being given to general conditions as may be shown by evidence or representations made by the parties affected. For the latter purpose a full opportunity is to be given for hearing at a public sitting of the board of all interested. Any order made shall go into effect on the minister's approval and its publication in the *Provincial Gazette* "at least 30 days before the day named for its coming into operation."

If any coal miner is paid less than the minimum wage to which he is entitled he may recover from his employer in civil action that which is justly due him. This will commend itself to all miners of British Columbia, and, in any event, it cannot be considered otherwise than a step in the right direction, evidencing on the part of the Government an active and direct interest in the question of the remuneration received by underground workers.

Board to Conduct Miners' Examinations

The appointment of a board of examiners "to conduct the examinations in any part of the province of applicants for certificates of competency" is another important innovation. At present this board consists of three coal-mine managers and three representatives of the men from different parts of the province, together with the chief inspector of mines. Its headquarters are in Nanaimo, B. C. Two of the men's representatives are from the Crows Nest Pass coal district, and in the past five years, on one occasion only has one of these representatives been able to attend a board meeting. While provision is made to pay the traveling expenses of those who have to come from a distance, this reimbursement by no means covered the loss of time that trips from various parts of the province to the coast entailed.

The result has been that the board often found it difficult to obtain a quorum. Its duties, too, have been merely of a supervisory character in connection with examinations. It called a meeting, set a date for examinations, appointed outside parties to prepare examination papers, forwarded these on their receipt to the various coal-mining centers, and, having received the papers, duly marked and passed upon by the appointed examiners, forwarded the results to the minister of mines.

It is felt that much of this procedure is useless and besides has had the effect of leaving functions of vital importance in the hands of a few, it being impossible in many instances, as has been shown, for the men's representatives to be in attendance at regularly called meetings. The proposal now is that the new board shall be composed of three members only, one being the chief inspector of mines, as chairman, and two others to be appointed by the minister "one of whom shall be appointed as representing the mine owners and one as representing the coal miners." It will be the duty of

this body, which will be small and by reason thereof able to move easily from point to point if necessary, to conduct the examinations.

The bill makes provision for another alteration in the conduct of examinations of miners applying for certificates of competency. Under the Coal Mines Regulation Act as it stands most of the collieries have their own boards for this purpose, the membership of which consists of a secretary appointed by the Lieut.-Governor-in-Council, a representative of the mine management and a representative of the men.

This arrangement, it is pointed out, was satisfactory so long as there were only a few large operating mines in the province. Conditions, however, are changed. There are now a considerable number of small collieries and, if each of these were given a board to which they are entitled under the act, there might be almost as many members of examining boards as there are miners coming up for examinations monthly.

The situation at the moment is that there are small mines such as that at Telkwa, in northern British Columbia; Coalmont and Princeton in the interior, and Granby and Nanoose on Vancouver Island that are without boards. Consequently, miners applying for certificates to work in any of the latter mines must travel considerable distances in many cases, to take their examinations. Telkwa miners, for instance, must come to Nanaimo; those of Coalmont to Merritt; and those of Nanoose to Nanaimo. In other words, if the method now in vogue were continued, it would be necessary to appoint at least five boards in addition to the nine now organized and some of these would have to be maintained in camps where the number of miners employed is exceedingly small.

Personnel of Examining Board

The board proposed to handle all examinations for miner's certificates of competency will eliminate this cumbersome machinery. Its personnel will be fixed in the same way as that of the board of examiners for "managers of mines, overmen, shiftbosses, firebosses, shotlighters and mine surveyors," except that the "inspector of mines for the district in which the examination is held" will be the chairman instead of the chief inspector of mines. The other two will be named by the minister of mines, one as representing the operators and the other the men. This board will have jurisdiction throughout the province and will move from colliery to colliery at frequent intervals in order to facilitate the issuance of certificates to those who can show that they are properly qualified. This will have the effect of fixing a standard of knowledge for coal mines throughout British Columbia; it will obviate the present difficulty of too much board representation at one point and too little at another; and it will be an added convenience both to the men and the management of collieries.

Another improvement in this connection is that no man will be admitted to a mine to work as a coal miner for a temporary period, pending his examination, as is now allowed. If a man applies for work as a miner and an examination immediately is impracticable he must go before the inspector of mines of the district who, having satisfied himself of the man's qualification, will issue him a temporary certificate. In such cases, however, those affected must go before the regularly constituted board at the first opportunity. The position taken by Mr. Sloan here is that it is a manifest absurdity to allow an uncertificated man to assume the responsibilities of a miner for 30 days without his knowledge being tested, it being possible in that period for an incompetent person to endanger, not only his own life, but that of hundreds of others.

Furthermore such a system, it is considered, will facilitate the control of the practice, where it has been followed, of permitting aliens to work underground. This is a matter on which Mr. Sloan feels strongly and he is confident that, when it is necessary that every man going to work as a miner for any period, no matter how brief its duration, shall prove his qualifications the employment of this class will be effectively checked.

A clear definition of the duties of a fireboss in a coal mine also is given by the amending measure, it being set forth that "the district of a mine assigned to any fireman shall not be of such size as to prevent him from carrying out his inspection duties under this rule in a thorough manner." It has been a standing complaint on the part of men holding this position as well as coal miners generally, that firebosses are handicapped in the faithful discharge of their duties by being required, in addition, to attend to haulage, pumps and various other matters with the result that often their duties at the working face have been neglected.

Defines Duties of Fireboss

It now is to be made law that this official shall "devote his whole time to his inspection duties," the exceptions being only "where the duties assigned to or undertaken by him in addition to his inspection duties are not such as to prevent him carrying out his inspection duties in a thorough manner." It is laid down too that this "shall not prevent the fireman being employed in measuring the work done by persons in his district, or in firing shots in his district, nor shall this provision apply in respect of any mine in which the total number of persons employed underground at one time does not exceed 30." It further is provided that "where any question arises as to whether any additional duties are such as to prevent a fireman carrying out his inspection duties in a thorough manner, the inspector of the district shall decide the question, and his decision shall be final."

One of the most vital of the amendments from the viewpoint of the safety of the mines and of the miners is that which states that, where the mine air in any working place is found to contain more than 2½ per cent. of inflammable gas, it shall be deemed dangerous and the men forthwith withdrawn. The Coal Mines Regulation Act now reads that at any time that the air is found by the person for the time being in charge to be dangerous the miners shall be withdrawn. Thus it is left to the individual judgment of one person to decide what is or what is not the danger point.

This is considered to be too indefinite and to leave too great responsibility on the shoulders of an official. Therefore it is proposed, as has been done in Great Britain, to fix a definite withdrawal point. It may be said, incidentally, that the percentage named as that at which danger commences has been applied by the department of mines, under agreement with the Crows Nest Pass collieries, to the latter coal field for some time.

The succeeding amendment is one which, it is thought, will mean the introduction of safety lamps in practically all the coal mines of the province. Such lamps, it is stated, shall be used, and none other, "in

any mine where the air current in the return airway from any ventilating district in the mine is found normally to contain more than ½ per cent. of inflammable gas." The wording then follows that of the Coal Mines Regulation Act as it now reads to the effect that such lamps must be used in every working approach to any places where there is likely to be found an accumulation of inflammable gas.

In addition to this, provision is made against any possibility of argument or misunderstanding as to how the percentage of gas in mine air is to be arrived at by the following sub-section: "The average percentage of inflammable gas found in six samples of air taken in the air current in the return airway from the ventilating district at intervals of not less than two weeks shall, for the purpose of this section, be deemed to be the percentage of inflammable gas normally contained in the air current."

The provision that "every winding rope shall be given a bath in hot oil before being installed; that every winding rope shall be recapped at intervals of not more than six months, and that no winding rope which has been in use for more than two years or which has been spliced shall be used for raising or lowering persons" no doubt is the direct result of the lamentable accident of last September at Protection Shaft, Western Fuel Co., Nanaimo, when a number of miners lost their lives through the breaking of a cable. The verdict of the coroner's jury, it will be recalled, was that the evidence indicated that the cause of this break was internal corrosion, the primary origin of which was lack of lubrication.

The question of the life of a steel cable is a matter which has been under discussion with no result for many years. Men of the highest technical qualifications have made investigations but no fixed standard as to the life of such cables has been yet arrived at. In Great Britain they may be used for 3½ years so that British Columbia is increasing what is considered an adequate margin of safety in England by 1½ years.

To try and prevent crystallization of chains it also is provided that "all cage chains in general use shall be annealed once at least in every six months, and detaching hooks shall be cleaned and refitted once in every three months."

Minecdotes

"Windy" Thought He Could Fire

Gibbs, the mine inspector, was always good for a story; so when he seated himself comfortably on the bumper of a loaded pit wagon, we knew that he was going to pass something along.

"You know, boys," he began, "that an inspector runs into all kinds of people. Today, I ran across a fellow that was so full of conceit, and so wise, that I offered to sell him my job for a cent. But talking about conceit puts me in mind of a fellow that I knew years ago, in fact I am still acquainted with him. He used to work for the Consolidated at the time when I was assistant superintendent.

"We had an up-to-date equipment in the power house. In the boiler room we had four 150-hp. return-tubular boilers. When we were hoisting coal good and lively it required a pretty good man to hold steam; but fortunately we had just that kind of a fellow, and he always had the pressure up pretty nearly where it belonged.

"There was a fellow dropping in empties under the tipple that we nicknamed "Windy"—and the name was not a misnomer either. Windy was continually pestering the life out of 'Slim,' the regular fireman. He was always telling him just how this and that should be done; how he used to 'burn 'em up' when he was steamboating on the river, and giving him a similar line of bull. He was such a pest that everyone was hoping that he would get the chance to prove his self-proclaimed ability in a practical manner.

"Well, one Saturday, and pay day at that, all the young fellows and a few of the married men wanted to attend a circus at a nearby town, and everybody was going to put forth his best efforts so that we would 'load out' about two o'clock. This would have given us ample time to have caught the local passenger train at 4 o'clock that afternoon.

"As it happened, Slim did not show up at the plant on the morning in question, and as I was temporarily in charge on account of the superintendent being on a vacation, I put Windy in the boiler room. And since he was more or less familiar with the duties that he was supposed to perform, no one gave him any particular attention.

"Everything went along about as usual until near 8 o'clock. It took 'Fat,' the hoister, about that long to warm up. When he did—well, he made that pair of hoisting engines eat steam. I had been pretty busy that morning and had forgotten all about Windy, when Fat gave my call on the signal whistle. When I poked my head into the hoistroom, Fat was sitting on his stool taking things easy. He pointed to the steam gage and nodded toward the boiler room—60 lb. of steam, blocked out on the bottom with loads, and top of this that bunch of men thinking of that circus.

"I went into the boiler room and tried to open the first firedoor that I came too. It was hotter than blazes, as were all the rest of them. Using a shovel, I got some of them open; the fires were banked on the dead plates and front of the grates clear up to the boiler shell, and the heat was terrific.

"What in the thunder is the matter?" I asked Windy. "I thought that you could fire boilers?"

"Fire!" he exclaimed, "of course I can fire, did you ever see a hotter fire in your life? Say, man, if these old kettles had any draft I could burn 'em up."

"Well, I fired Windy out of the place, bag and baggage, for the boys would have mobbed him after his getting us in such a mess as that. However, with the help of the oiler, we got things started again, but we didn't load out until about quitting time. Windy left the camp and it was a long time before I saw him again. He is still full of conceit, the same as always."

"Where's he at now?" asked Williams, the boss hauler

"Oh, that is the fellow that I ran into today up on 2d East entry, the fellow that I offered to sell my job to for a cent," answered the inspector.

Modern Shaft Development of the Consolidation Coal Company—II

By George W. Harris
Editorial Staff, *Coal Age*

THE underground development at the No. 87 mine is entirely in keeping with the surface improvements—nothing for show but everything substantial and carefully thought out. In this connection the comment of a progressive coal man comes to mind—he always endeavored to secure the best talent he could find to fill the position of mine boss. On the surface all was open to the light of day, but underground there was infinite opportunity for leakage and it was considerably more difficult to keep track of matters—the running of the whole plant is affected by the movement of coal to the shaft.

In a section with a topography like West Virginia the first consideration in locating a mine opening is to place it so that the tipple taking the coal from it can be reached by a railroad. In the case of mine No. 87, the location of the shaft being decided upon, the layout of the mine came up for consideration.

The faces and butts of the coal determine the course of the entries. The face headings and rooms are on the line S 12-30 W, and the butt headings are S 77-30 E or the reverse—N 77-30 W. The next important consideration influencing the layout of the mine is the location of old and new gas wells—it is necessary to have the mine workings miss them all. An adequate pillar of coal must be left around each well, the size of this pillar being determined by the amount of cover over the coal at the well. The Consolidation company has adopted the following rule governing this matter:

Cover	Size of Block of Coal
200 ft. or more	200 ft.sq.
200 to 100 ft.	Decrease 1 to 1
100 to 20 ft.	Decrease 1 to 2

For example:

225 ft. cover requires a block 200 ft. square
165 ft. cover requires a block 165 ft. square
100 ft. cover requires a block 100 ft. square
80 ft. cover requires a block 90 ft. square
50 ft. cover requires a block 75 ft. square
20 ft. cover requires a block 60 ft. square

It was decided that no protecting block should be less than 40 ft. square and none more than 200 ft. square.

A number of gas wells are located on the map of the territory to be covered by mine No. 87, some of them being shown in Fig. 9. Here the protecting pillar of coal is outlined. The proper protection of these gas wells is a matter of interest to coal operator and gas well operator alike, and coöperation between these two interests is the rule. When a gas well is to be drilled both parties discuss the situation and its final location is determined after consultation. Its exact location is then noted on the maps by the engineers. The Pittsburgh seam at this mine runs from 7 to 8 ft. thick and is reached by the main shaft at a depth of 482.5 ft. The main shaft bottom is shown in perspective in Fig. 7 and in plan and profile in Fig. 8; the top rock was taken down on either side of the shaft and the top and sides were concreted for some 115 ft. with a clearance over the rail of about 15 feet.

It is an exceptional shaft bottom. There is ample room for all operations—the handling of cars and materials. A 34-ft. rail can readily be transferred from the cage to the workings, a result greatly facilitated by the height of the top and its shape at this point. A free use of whitewash and electric lights decrease the chance of accident and increase the speed of handling cars at the bottom. The method of car movement at this point is shown on the plan and profile, Fig. 8, which notes track grades and the disposition of machinery. A car feeder (made by the Fairmont Mining Machinery Co.) moves loads to the scales, where they are weighed, after which a 3 per cent. grade handles them to a Lepley automatic car cager (made by the Connellsville Manufacturing and Supply Co.) which places

FIG. 7. MAIN SHAFT BOTTOM OF NO. 87 MINE

them on the cage at the right moment. On the empty side of the bottom favorable grades handle empties to a car pusher which facilitates the making up of trips for the motors.

Before going into mine No. 87 a person can notice signs placed at critical points about the plant which read, "Be Careful Here"; workmen and others are cautioned to be on their guard at possible danger points. On alighting from the cage at the main shaft bottom, or when attending to the many duties about this spot, men are again confronted by the same good advice. On one wall facing the shaft is the notice "Safety First," as shown in Fig. 7; on the opposite wall on the other side of the shaft has been painted "Be Careful." This should be the most active spot in the whole mine, and danger signals can be made prominent here to great advantage.

The details of railroad yards are matters of grave

concern to the management of transportation systems, for here trains of loads and empties are made up and congestion at this point cripples the efficiency of the railroad. There is greater necessity to plan an underground yard carefully at the start than one on the surface, for mine tracks cannot always be changed at will. When a mine is once opened up and entries driven, the pillars of those entries around a bottom are required to protect the shaft and should not be weakened by extensive changes in plan. The No. 87 mine development is given in Fig. 9; the heavy lines indicate the opening on Dec. 21, 1917, and the light lines the projected extensions. The main development of this mine is planned to go to the north, east and west, and the coal is to be worked out on the room-and-pillar panel method developed on the block system.[1] The mine was projected to follow the plan shown, but conditions may be such that fracture lines will be reversed when robbing starts.

The development, as shown in Fig. 9, was not simply a place to secure coal; a number of conditions influenced

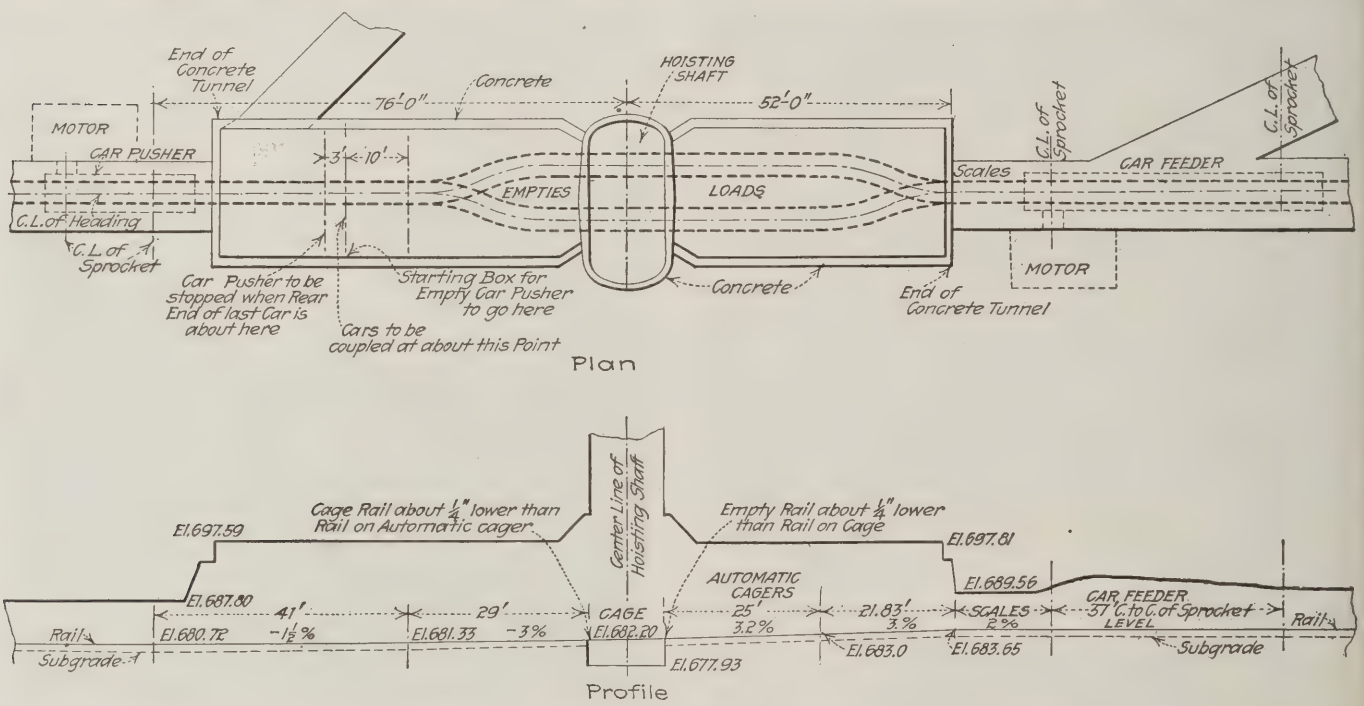


FIG. 8. PLAN AND PROFILE OF THE SHAFT BOTTOM AT NO. 87 MINE

the mine layout, as previously noted. Furthermore the mine was opened up so as to have as much room in the intake as in the return. It was thought that at least seven intake entries should be planned; with an entry cross-section of 6 x 10, this would give a total area of 420 sq.ft.; it would permit a capacity of 420,000 cu.ft. of air per minute for the seven entries, with a velocity not greater than 1000 ft. per minute. It was not desired to have a great excess of air, as it would tend to dry out the mine, but sufficient area was planned to allow for falls of rock in the main air courses and still have an adequate area. Provision was made so that two or more additional entries could be driven if a larger volume of air was found necessary and still not interfere with the present development.

When the No. 87 plant was opened up the intention was to pull the loaded trip direct to the shaft bottom, but on account of adverse grades encountered the trips are pulled past the shaft and backed in to it. The grades shown on the profile, Fig. 8, required little grading to establish them; it would have been impracticable to have reversed them, placing the loaded siding where the empty tracks are now and vice versa.

A person will be rewarded by a study of the mine map, Fig. 9, with information regarding the method of development, an idea as to lines of haulage, ventilation, and so on. The course of the air current is indicated by arrows. In a number of instances where two intake airways cross return airways, and crossovers are required, then the intakes are merged into a single opening of enlarged area to save the expense of making two concrete crossovers.

The successful transportation of coal underground depends on good tracks and rolling stock much the same as on the surface. As contributing to serviceable tracks it is planned to use 60-lb. rail on main haulage roads, 40- and 30-lb. on butt entries, 30-lb. on some rooms and 20-lb. on the rest of the rooms. The motive power is to be 10-ton General Electric locomotives on main lines and Goodman storage motors with Edison batteries for gathering cars.

Power is taken from the surface down the shaft by cables which are suspended in fiber conduits. The conduits were placed in the concrete lining of the air shaft when it was concreted, additional conduits being provided at the time to be available should extra cables be required later. These conduits were furnished by the Fibre Conduit Co., of Orangeburg, N. Y. Good transportation of coal is further strengthened by the types and number of mine cars used. Here a 3-ton mine car with iron sides and ends, and wood bottom, made by the Fairmont Mining Machinery Co., is used; Enterprise Foundry and Machine Works (Bristol, Tenn.) roller bearings are employed.

The coal is undercut mainly by Goodman breast min-

[1] A description of this system was given in the Dec. 26, 1918, issue of *Coal Age*, under title of "The Consolidation Coal Company."

ing machines, although a few of the shortwall type are used. All mining machines are driven by inclosed, explosion-proof, direct-current motors. The company is experimenting with a coal drill made by the Fairmont Mining Machinery Co., the drill being mounted on the motor case of the mining machine; this drill readily can be taken off when it is not in use, and it also has an explosion-proof motor. The mine is unwatered as follows: A number of small 2-hp. Fairmont No. 1 portable pumps mounted on a truck and driven by a small motor gather water from local dips and deliver it to a main sump; from this point the water is pumped to the surface by a four-stage, 100-hp., 2300-volt induction motor-driven centrifugal pump.

On coming over the hill from Carolina, or mine No. 86, toward Ida May, one would see the latter town spread out before him as shown in Fig. 1 (see first installment of this article, page 480, Mar. 13, 1919, issue of *Coal Age*). The most prominent features in this scene are the plant around the two shafts toward the left, the store in the immediate foreground, the tipple and the long rows of miners' houses on the hillsides and ravines. Among these latter are the homes of the local officials of the company, in the foreground at the right. In the foreground in the center is the basement of what will be a new school, whose completed outlines are shown in Fig. 10. It is a town with great possibilities, and the company's plans call for improvements which will furnish an incentive for the better class of men to bring their families to this town and make their permanent homes there.

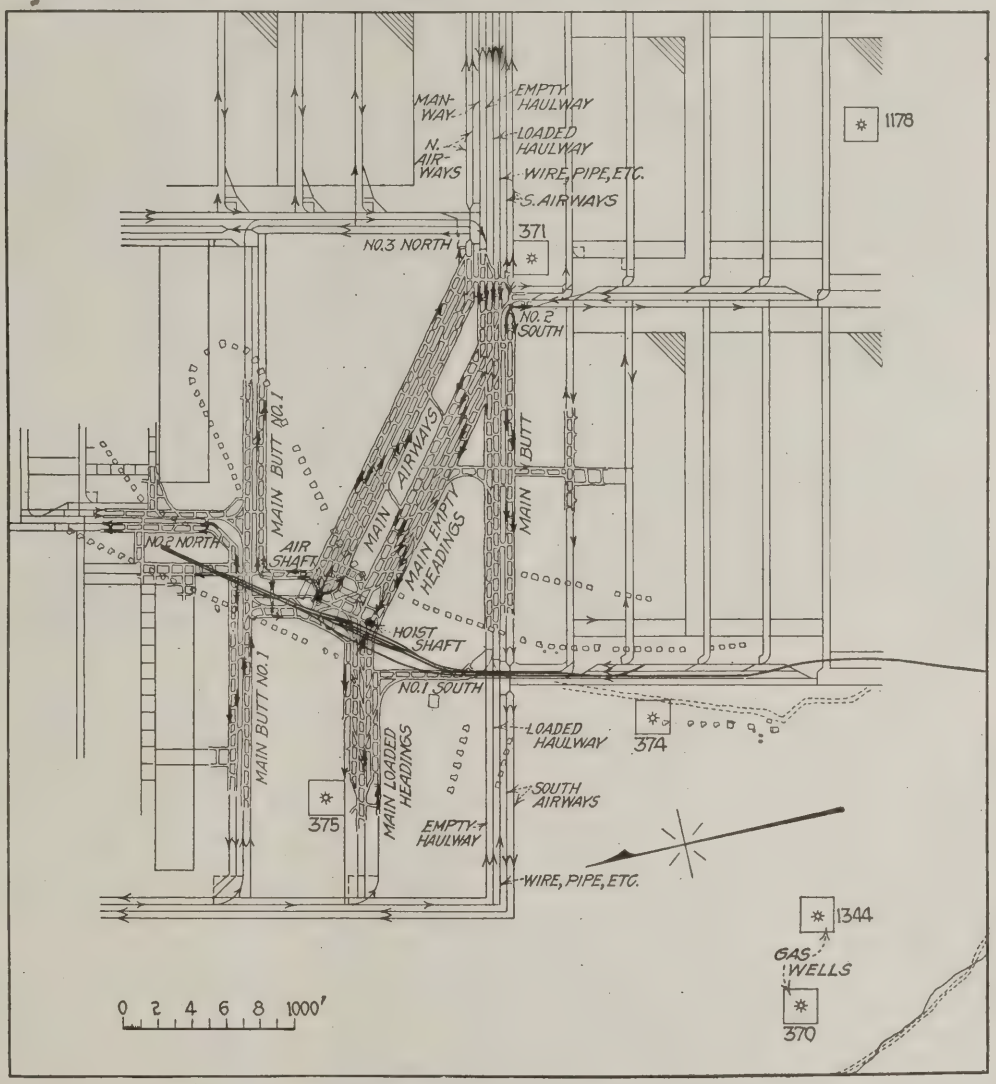

FIG. 9. DEVELOPMENT AND LAYOUT OF NO. 87 MINE

There are several types of houses in the Ida May town, from the three-room single house to the larger double one. However, all are piped for water and natural gas and wired for electricity. A pure water supply is furnished the population of this mining town and sanitary conditions are further looked after by a comprehensive drainage system, which conducts waste water from each home to the creek by which it is carried off. A dozen or more homes have fully equipped bathrooms; they include the superintendents' and doctors' houses, six 6-room cottages and five 5-room houses. These buildings are shown at the extreme right and left in the foreground of Fig. 1. The water supply for the town comes from Taggarts Valley River and is furnished by the Monongah Service Co. A reserve supply is maintained near the town in three tanks on the tops of adjacent hills; a water pressure of 125 lb. is thus maintained and can be fed to boilers when the steam pressure is slightly below water pressure.

Of almost equal importance to an adequate and pure domestic supply of water is up-to-date means of handling waste water. Open drains generally conduct sewage from the miners' homes at this town to main drainage lines which finally empty into the creek; catch basins are built at points where they are required and glazed pipe carry the main sewage system under roads. The type of plumbing installed in all the company's houses is simple, with 4-in. connection to the drain. The open drains seem to be working out satisfactorily and are simple of construction. At the houses they consist of a 3-brick section; a brick at the bottom is laid lengthwise of the drain and one brick at each side forms the slopes; the latter are set with the length at right angles to the bottom line of brick. To protect the drain against disturbance from frost, the ground is excavated to a depth of about 10 in. below grade, then a foundation is built of 6 in. of broken stone or cinder, on top of which is placed 4 in. of concrete; the surfacing brick are set in this concrete. Main open drains are similarly constructed, but with a larger cross-section and foundation. Cement finds free use in and about mines today. At Ida May the top soil contains considerable clay in places, and those who have encountered this ob-

FIG. 10. ARCHITECTS' DRAWING OF IDA MAY SCHOOL

stinate impediment to foot travel in the country at certain seasons of the year should rejoice with those who have cement sidewalks. Such walks are planned to be laid on the principal streets of Ida May, connecting the houses with the store and other parts of the plant; a good beginning has been made in this direction. A 4-in. sidewalk is built of a 1:2:4 mixture on a foundation of 10 in. of cinder.

This town is lighted by a modern series street lighting system, including pipe bracket fixtures, porcelain enameled reflectors and Mazda incandescent lights. A time switch is installed which automatically turns on the light at dusk and extinguishes it at dawn. A "white way" has been established in the center of the plant by the use of two floodlights so placed in the vicinity of the tipple on high poles that a considerable section is well illuminated. New possibilities for lighting large outdoor areas have recently been brought about by the use of floodlights with high power (tungsten) lamps. The type of installation, according to the *Railway Review*, must be carefully selected to suit each individual case, and whereas flood lighting has recently come to the front as an economical means of lighting large areas, it must be used correctly to be effective. It has been used recently for protective lighting to enable watchmen to detect trespassers; under favorable conditions it is said that a 400-watt floodlight will show up a man in dark clothes at a distance of a thousand feet. This system is economical in quantity of current required, in cost of installation and in maintenance. It is not so new as to be an innovation, and yet it is not in such general use as it may become in the near future. Such lights are furnished by the Crouse-Hinds Co., of Syracuse, N. Y., and the Western Electric Co., of New York.

Natural gas is a boon to the domestic user of this convenient form of fuel, although it seems something like "carrying coals to Newcastle" to pipe fuel to a community living around a coal mine. Four-inch gas mains are laid all around the town of Ida May and connect with the gas wells of the Monongahela Valley Traction Co. The 6-in. water mains not only furnish a supply of water for domestic purposes, but also make possible adequate fire protection to the town. At every sixth house along a street there is a hosehouse in which there is a reel of 250 ft. of hose. This length of hose covers half the territory between fire plugs, and with an ample head and supply of water this equipment should do good service in emergencies.

A large proportion of the population about many of our coal mines is often foreign-born, as witness the make-up of the employees at mine No. 87, which includes: Italians, 22; Hungarians, 35; Poles, 7; Croatians, 4; Russians, 2; Spaniards, 2; or 72 out of a total of 187; the remaining 115 being made up of American white, 75; and American colored, 40. There is every reason why the children of this foreign-born element should be properly educated and also that the parents should be Americanized. The Consolidation company does not neglect this great opportunity and provides or assists in the maintenance of educational facilities at its mines, many of which compare favorably with city schools of like grade. A view of the Ida May school now building is shown in Fig. 10. In the basement of this building there will be three rooms for manual training, domestic science and gymnasium work respectively; on the first floor there will be two rooms for the regular schoolwork, one of the rooms having folding doors so that it can be used as a double room when necessary. The school will be heated by gas stoves. It is a substantial brick fireproof building of pleasing appearance.

Improving Recreation Facilities

A nearby store at which the employees can trade is a practical necessity at Ida May; the building, which is shown in Fig. 11, houses the various departments of the store and office at this new town. An interior view of this store is shown in Fig. 12. This company has over forty stores in the various districts in which it is operating, and prides itself on the advantages it thus offers to its employees. The recreation features of the Ida May community are under development. One of the original houses on the property before improvements began has been fitted up as a temporary recreation building; pool and billiard tables have been placed in it and it is also used as a general lounging room. Plans have been made for a new building which will include facilities for many forms of indoor amusements. This company has built extensive recreation halls at several of its operations remote from large towns; several of them have a theater where some of the best moving pictures are shown. In season outdoor sports are encouraged. The local baseball team has a fine diamond on which to practice, and it improved the opportunity to such an extent that it won the championship for three counties during the past season—21 games were won and only four lost. All the men on this team are employees in the No. 87 mine. An illustration of this team was shown on page 57 of the Jan. 9, 1919, issue of *Coal Age*.

FIG. 11. CONSOLIDATION STORE AT IDA MAY

The official family responsible for the smooth running of mine No. 87 includes C. H. Tarleton, manager of the West Virginia division of the Consolidation; W. J. Wolfe, superintendent of both Ida May and Carolina; William McMahon assistant superintendent; C. H. Shear, outside foreman; O. L. Bush, pitboss, and J. E. Jeffries, chief clerk. In addition to those noted previously in the text of the article, the following have placed the stamp of their individuality on this plant:

FIG. 12. INTERIOR VIEW OF FIRST FLOOR OF THE IDA MAY STORE

The Allen & Garcia Co., of Chicago, Ill., designed and erected the tipple, and the machinery was furnished for the tipple by the Fairmont Mining Machinery Co., of Fairmont, W. Va. *Coal Age* is greatly indebted to the Consolidation officials and to the designers of the plant for information, photographs and drawings which were used in the description of an operation which possesses features of unusual interest.

Treatment of Acidulous Feed Water for Steam Purposes

By E. A. Reilly
Pottsville, Penn.

In the treating of water for steam purposes, whether it be only slightly impregnated with organic acids or strongly acidulous with mineral acids, it is recommended that soda ash or caustic soda be used in their neutralization. The use of soda ash is preferred because it is less difficult to handle and will give practically the same results as caustic soda. Any water that is properly treated with either soda ash or caustic soda can be used in boilers without any corrosive effect, either on the boiler shell or on the tubes. It is the opinion of many that the addition of caustic soda or soda ash to a water will cause it to have a corrosive effect on the tubes of the boilers, and make them leak. This idea is absurd and untenable, arising as it does from an unreasonable theory.

The only reason for having leaky tubes from a water that has to be treated with an alkali is that an insufficient amount of the alkali is being added to the water to neutralize its acidity; or it may be that the tubes contain sand spots, or small holes that have been covered over by scale or oxides of iron, and the alkaline water coming in contact with these will have a tendency to loosen such scale from the tubes, causing them to leak. This, in no way, can be blamed to the use of the alkali, as the tubes were defective before the use of the treated water was started.

An idea of the process of treating an acid water for use in boilers might well be given here. First, the amount of water used per day (24 hours) must be known; secondly, the acidity of this water is determined, and from this acidity is calculated the amount of alkali required to neutralize the water. After learning how much alkali is needed for every 10,000 gal., or whatever amount of water the supply tank holds, the alkali is dissolved in warm water and added to the water in the supply tank. The whole is then thoroughly mixed and then tested to see whether it is properly treated.

After the water is properly treated, it is run off into settling tanks and allowed to stand until the precipitate settles; the clear solution is then decantered and is fit for boiler use. Before the water can be said to be properly treated, it should show Na_2CO_3, $NaHCO_3$ or NaOH. It might be mentioned that the foregoing directions apply to the treatment of a mine water, the occasion for which occurs seldom. Waters that are only slightly acid in nature can be treated by the addition of a small amount of alkali (calculated) in three portions at different times of the day. This may be dissolved in warm water and injected either into the tail pipe of the pump or into the supply tank. This will give quite satisfactory results and will be less expensive than other methods in use.

To show that waters of strong acidity, after having been properly treated, can be used without causing trouble, a few examples will be given. One water before treatment showed: Total solids, 384 parts per million; total acidity as sulphuric acid, 44 parts per million. The same water after treatment showed: Total solids, 499 parts per million; alkalinity as $NaHCO_3$, 168 parts per million. The use of this treated water in the boilers gave satisfactory results; but if the water had not been properly treated, trouble from leaky tubes would have been experienced. This, in the opinion of some, no doubt would have been attributed to the use of the alkali, whereas the real trouble would be due to some of the acid remaining in the water and going into the boilers.

As another example of the use of acid water which gave no trouble after having been properly treated the following is given: Before treatment the water contained a total acidity as sulphuric acid of 461 parts per million. As can be seen, this was a very bad water, but after treatment it was used with good results.

A third example is the following: Untreated water, total acidity as H_2SO_4, 894 parts per million; total solids, 3655 parts per million.

This water, while very bad, was successfully treated with soda ash and no trouble from corrosion was experienced. The treatment required about 68 lb. of soda ash per 1000 gal., showing that the water finally contained a large amount of sodium salts.

When a water such as this must be used, blowing off of the boilers and cleaning as often as possible is a necessity. When the boilers are pushed too hard, and a water like that mentioned above is to be treated and used, foaming may occur, this condition being due to the large amount of dissolved salts in the water and to the overworking of the boilers. This will not, however, cause corrosion. As this article only intends to deal with the corrosion end of feed water, the foaming of waters will not be taken up.

To make the effect of acids and alkalies clearer to those who have any doubt about the corrosion of iron by soda ash, or caustic soda, the results of a few practical tests will be given. These tests were made on iron strips of the same constituents as that of which the boiler tubes are made.

Water No. 1

Carbon dioxide (CO_2)	2 parts per million
Calcium carbonate ($CaCO_3$)	5 parts per million
Methyl red	Alkaline

From this water there was a slight corrosion.

Water No. 2

Carbon dioxide (CO_2)	2 parts per million
Calcium carbonate ($CaCO_3$)	3 parts per million
Methyl red	Acid

From this water there was a pronounced corrosion of the iron.

Water No. 3 (treated with soda ash)

Sodium hydroxide (NaOH)	16– 4 parts per million
Sodium carbonate (Na_2CO_3)	784–85 parts per million
Methyl red	Alkaline

This water was noncorrosive.

Water No. 4 (treated with caustic soda)

Sodium hydroxide (NaOH)	424–92 parts per million
Sodium carbonate (Na_2CO_3)	424–11 parts per million

This water was noncorrosive.

Water No. 5 (treated with soda ash)

Sodium carbonate (Na_2CO_3)	11 parts per million
Sodium bicarbonate ($NaHCO_3$)	8 parts per million

This water, after a long test, showed but the faintest signs of corrosion; that is, it showed corrosion by giving it the benefit of the doubt.

This water, it might be said, was just about alkaline.

Water No. 6 (untreated)

Carbon dioxide (CO_2)	Trace
Calcium carbonate ($CaCO_3$)	5 parts per million
Methyl red	Alkaline

This water was corrosive, though only containing a trace of weak acids.

Water No. 7 (untreated)

Total acidity as sulphuric acid (H_2SO_4)	1,588 parts per million

This water resembles a mine water and had a most active reaction on the test piece.

From the foregoing tests, it can readily be seen that acidulous waters to be rendered noncorrosive must be treated with an alkali, and by using an alkali the waters will not have a corrosive effect on the tubes or on the shell of the boiler.

To those who do not use methyl red as an indicator in water purification work, I recommend its use for determining the nature of a water as far as corrosiveness is concerned. With this indicator one can learn whether there are acid salts in the water, which are highly corrosive agents, and which must be neutralized by an alkali.

Orient Mine Smashes All Records for an Eight-Hour Hoist

There is a race on between the American Coal Mining Co. at Bicknell, Ind., and the Chicago, Wilmington and Franklin Coal Co.'s Orient mine in Franklin County, Illinois, for the honor of making the largest hoist of coal in an eight-hour day. The last high record of the American mine was 6128 tons in eight hours, which is of course a wonderful record for a single-car self-dumping cage.

The Orient mine on Mar. 5 hoisted 6422.20 tons of coal in 1401 dumps. The hoisting time totaled 7½ hours, the approximate length of hoist being 570 ft. On Mar. 6 the same mine hoisted 6776.75 tons in 1502 dumps. The hoisting time was eight hours, only eight minutes being lost during the day.

During the month of February the Orient mine averaged over 5200 tons per working day. This mine also steadily increased its output during the war when other mines in the same field were losing tonnage due to labor shortage and other troubles. The operation is remarkably efficient and the fine results are due to the well-directed efforts of the management—G. B. Harrington, president; T. F. Holmes, general superintendent, and Joseph Louis, mine superintendent. Not the least factor in the record hoists is the splendid coöperation of the employees.

TO FACILITATE THE BURNING of the finer particles of anthracite coal and coke, mixtures of these fuels with bituminous coal have been tried. In this connection it has been found that non-coking bituminous coal is considerably inferior to the coking variety. The coking coal is better adapted to this use on account of the coal fusing at a comparatively low temperature; the particles of culm are taken up by the fusing coal and a homogeneous mass of fuel formed which burns uniformly. Tests show that a mixture containing 30 per cent. of culm, or coke, and 70 per cent. of coking bituminous coal produces the best results in burning.

Will Wages and Prices Remain Stable?

By Arthur F. Rice
Commissioner "Coal Merchants' Association, Inc."
Room 608, 90 West St., New York City

IN THE issue of *Coal Age* of Mar. 6 appeared an editorial entitled "A Clever Augur Can Find Whatever He Will." The writer of that editorial takes issue with me relative to my prophecy that there would be a reduction in the price of coal. As I had good reasons for the opinion I offered, I make the following statement, which explains why I have taken the stand which the editorial criticized.

First let me say that I prefaced the remarks to which the editorial refers by saying that he would be an optimistic man who expected these downward changes to take place at once. It is undoubtedly true that prices for the essentials of life must be lowered before there can be a substantial decrease in wages. I realize that when labor has made agreements with employers, those contracts must expire before new wage scales can be made effective. Employers must keep their promises even if labor does not.

We have seen an instance of the irresponsibility of labor in the boatmen's strike in New York harbor, where the men absolutely agreed to abide by the decision of the War Board and then coolly repudiated that contract. Such contract breaking does not in the long run help labor, and capital is not likely to imitate it. Even labor cannot continue to treat an agreement as binding when favorable and as a scrap of paper when unfavorable.

However, the anomaly of unemployment and contemporary high wages never had a long run. The law of supply and demand may not work quite so suddenly as the law of gravity, but it works just as surely, irrespective of what anybody wants or thinks.

For reasons which have seemed good and sufficient to the present administration in Washington, labor has had anything and everything it wanted; and there appears to be no present limit to this Government subservience. However, giving too much candy to children is likely to make them sick, and too lofty flights result in the most fatal falls. I fail to find in economic history any instance where, with two men for every job, one continued to get double pay while the other got nothing. Even unionized labor cannot lift itself over a fence by its boot straps.

When the editorial states that "prices of materials will not decline and wages will remain where they are," it expresses a conviction that is not borne out by the facts of commercial history; in fact, the prices of many commodities are already coming down—for instance, copper, which was selling at 26c. is now around 15c.; the other metals are on the same downward scale. To a huge surplus of wheat another tremendous crop is about to be added, and cold-storage warehouses are bursting with pork and beef. The only way to make money is to sell goods and produce more goods, and if the supply exceeds the demand, the remedy lies not in high prices but in lower prices, Mr. Hoover to the contrary notwithstanding. His prediction of $3.50 wheat is the "phantasmagoria of a diseased imagination." When you throw a stone out of the window and it goes up instead of down, you may then believe that prices in a heavy and glutted market will rise rather than fall. Anyhow, I will stake my judgment against that of the writer of the editorial that before the appearance of the April issue of *Coal Age* building materials and a lot of other commodities may be easily bought at lower prices than those prevailing today.

A reduction in living costs will render a reduction in wages logical even if not, at present, practicable; and a reduction in wages and materials which enter into the cost of producing coal would enable many an operator to make a profit where he now claims to be taking a loss. The editorial takes the ground that "it is just as well that the high level of wages remain stabilized," which necessarily implies that the high prices for coal shall also continue; but there I take direct issue, having in mind solely the good of the business itself for the immediate future.

Speaking of anthracite alone, and with especial reference to the steam sizes, the prices have been too high to enable this form of fuel to successfully compete with gas, electricity and soft coal, and they are too high here today, notwithstanding the fact that the retail dealers in New York, on the day after the Fuel Administration went out of business, reduced the prices on an average of 35c. a ton and now seriously contemplate making them lower. With gas at 80c. and gas stoves being practically given away, with the electric companies making a systematic (and successful) campaign to get their current into hotels and office buildings, and soft coal and coke in abundance at constantly falling prices, what can the ultimate outcome be, except a huge and permanent loss in anthracite tonnage? There is, in my estimation, but one way in which these tremendous inroads upon the business can be stopped, and that is by lowering the prices on anthracite steam coals, with the added proviso that their preparation be so improved that they may contain a lot more British thermal units and vastly less slate and dirt. The editorial says, "let us pin our faith on facts, not on visions"; and so say I. But let us be mighty sure about our facts! nor forget that a little "vision" and foresight are as essential in the coal business as in any other. A temporary loss of profits is bad enough, but the permanent loss of business is much more serious.

Anthracite culm, slush or silt contains approximately 70 per cent. of combustible material. For some time experiments have been conducted by the large anthracite companies to reduce the impurities in this material to a point permitting of transporting it to a distance. Some of the devices employed in bituminous washeries have been successfully used in anthracite operations. Recently, concentrating tables such as are used in metal mining have been discussed and experiments are about to be tried as to their efficiency in the preparation of smaller anthracite sizes.

Extending the Coal Operator's Field for Profits

By George H. Cushing
Managing Director, American Wholesale Coal Association, Washington, D. C.

AN EDITOR of a daily paper overheard one of his reporters delivering an oration to his fellows. It was vigorous to the point of being vicious. He was overworked, he said, because the management was unfair. He pictured everything was going to the demnition bow-wows. At the conclusion of the diatribe, the editor said quietly:

"My boy, sometimes you talk as though you had a hair in your mouth."

Then he called the reporter into his office and said:

"I am glad to hear you talk that way. It doesn't prove, as you claim, that the paper is going down hill or that the management is bad. It merely proves that you have become discontented because you have outgrown your present job. It is time for me to give you a promotion."

Then he inquired patiently into the young man's ambitions. Before the week was ended, he had satisfied them. This is a true story. I know it is because I was the reporter.

The Coal Industry Wants a Change

The coal trade these days talks as though it had a hair in its mouth. It condemns everything which was, is, or is likely to be. It is not satisfied with anything. It wants a general change. According to the old editor's philosophy, that is a hopeful sign. It is an indication that the trade is dissatisfied because it has grown. It indicates that it needs a promotion. That being true, it is high time to discuss quietly the trade's ambitions to see whether they can be satisfied.

Frequently today one hears it said that coal should be under one control from the face to the smokestack. That is, the man who produces it should wholesale and retail it.

That is a good idea—if it can be carried out. It is a good idea because it rests on the theory that no industry is ever really profitable until it reinvests its money several times and, thereby, comes to get a profit on each process in the business.

To put it another way, it means that there should be a profit on mining, a profit on wholesaling and a profit on retailing. The operator, therefore, having made a profit on mining should reinvest it in wholesaling. When he has made a profit on both mining and wholesaling, he should reinvest it in retailing. Thus, in the end, he would come to have three separate profits on the original investment. In the end, therefore, he would have a business three times as profitable as it was in the first place, but without inviting any new capital into his enterprise.

You may multiply this process *ad libitum* by saying that the operator should also invest part of his profit in a coking plant. This starts another pyramid. That is, having a profit on mining and on coke making, he might reinvest that in the development of byproducts. This latter expansion can go on indefinitely.

The theory is perfectly sound because it has been worked out in other lines. That, in fact, is exactly the foundation of the fortune of John D. Rockefeller, who treated oil in that way and made therefrom America's greatest fortune.

It was precisely the same theory which constituted the foundation under the great department stores. Also, it is the foundation under the packing business. There is therefore no need to justify the theory. It is the established truth of business that the reinvestment of earnings assures larger earnings—if each department of the expanded business is independent of the basis department, and if each department makes a separate profit.

Before coal can launch successfully upon any such an expanding program, a few vital preliminaries must be attended to. The most important of these is to establish the essential distinctness of the operating functions, the wholesaling functions, the retailing functions. As a natural corollary, it must be recognized that since each has its separate capital, service and expense, there should be a profit commensurate thereto. We must come not only to the theory of three profits rather than one on the coal business. We must deliberately set out to make each department actually profitable. That is a condition precedent to the success of any such an expanding venture as the coal men now propose. In a word, the operator does not want to reinvest his mining profits in either wholesaling or retailing until those departments are profitable. To do so would be only to make money in one way to lose it in another. Thus, the best thing to do is to make these other departments profitable, to pave the way for a safe reinvestment of mining profits.

May Bite Off More Than It Can Chew

There is necessary another quite important preparation for any such an expanding program. Before the mines generally dare launch themselves upon any such an enterprise, they will want to be reasonably sure they can finish what they start. Otherwise they might find themselves in the position of the hopeful son who went forth one evening to propose marriage to a girl and took out a license first.

That is, if the operator is going into the wholesaling business, he must first make sure of enough tonnage to keep his wholesale organization busy. Along this line, I often recall the sound advice of a minister of the gospel, to wit:

"If you are thinking of marrying, there are three necessary preliminaries—good health, a visible means of support and a girl."

So, if the mines are to venture beyond the zone of production into wholesaling, they want to be sure that they have the tonnage, the money to finance the deal and the market.

Going back over the history of the trade, a few conspicuous cases will develop an important truth or two at which the coal trade has arrived as a result of broad experience.

At first the Pocahontas operations were small,

naturally. They could not sell their own coal so they entrusted the selling of it to a wholesale concern. After a while, it became apparent that the wholesale company was making more money from its efforts on all of the coal than was any producer from operating his mine. This didn't seem quite the thing to encourage.

In the meantime, each producing unit was growing. Some grew through natural expansion. Others through consolidations of individual mines into good sized companies. After a few years of that sort of thing, the operators decided to break away from the wholesaler. The enlarged mining companies decided to undertake the selling end of their business. Thereupon, they had the choice of two methods: They could buy out the merchandising concern; or, they could establish their own sales organization.

The decision along the latter line was made for two reasons: First, in a central selling syndicate supported by a number of mines which are financially independent of each other, it is hard to convince each operator that when business is poor the orders are being equitably distributed. Second, each company in that field had grown to a point where it produced a tonnage big enough to justify it in maintaining its own selling organization. The lessons learned by that experience are that small mines must depend on wholesalers. But they naturally break away so soon as they are independent of that agency which helped them to grow. This seems a harsh doctrine, but it is obviously the law of business.

Centralization of Sales and Distribution

Originally, as is commonly known, the mines now embraced in the Consolidation Coal Co. were controlled by a diversified ownership. Some mines were quite small and had to depend upon wholesale merchants for a market. Others were somewhat larger and were struggling to maintain their own sales organizations. It was decided, finally, to try to sell all of the Fairmont coal direct or without the aid of wholesale merchants. Thereupon arose the old question: "How can we centralize sales and satisfy the producers that orders are equitably distributed?"

The answer to that question was: "Consolidate the companies which control the mines and thereby get into one organization an annual tonnage big enough to support a separate selling organization."

This was done. After a little experience, the management learned two things which enabled it to adopt a distinctive policy for this concern. These two things were: First, the major portion of its tonnage was sold to the steam and gas trade. This coal had to be sold but once to put it into the hands of the ultimate consumer. There was little need—when the tonnage was large—to ask for help in selling this coal. Second, a very small percentage of the tonnage, relatively, was moving to the retail trade. And this coal was sold in such a restricted area, it justified that company in the ownership of retail yards. That is, only a few yards were needed to distribute this retail coal. Therefore, the producer's investment in retailing was not out of proportion to his business.

The lessons from this experience are: A central selling organization is safe when the mines which feed it are consolidated. A producer can safely retail his own coal when his tonnage in a given locality is large enough to support a retail yard.

The Pittsburgh Coal Co. is another example of the same kind of an experiment; and the development of its business has been along almost identically the same lines, with almost identical results. Two experiences are more convincing than one. But they become a safe criterion only to those facing similar situations—namely, a large volume of steam coal going to highly specialized use and a volume of retail coal moving into a few big centers.

A fourth and a far more complex example of direct selling comes in the case of the mines in Franklin County, Illinois. The area under development there is relatively small. At first the number of separately owned producing companies was relatively large. The coal from these mines was sold over eighteen states. On these various accounts, it was a financial impossibility for a single mine, with relatively a small tonnage, to sell its coal profitably at wholesale by its own agents over those eighteen states.

Even to think of each mine putting its own retail yard in each one of the cities in each one of those states to handle that coal was so far out of the question as never to have entered the mind of any producer. The investment in the requisite retail yards would have been immeasurably larger than the total investment of all mines in the producing district.

After about five years of discussion, however, it was finally decided to consolidate some of the mines in the Franklin County field. The result was one large company with a producing organization yielding a big enough tonnage to warrant it in wholesaling its own coal over its entire market. But even this experiment was not financially justified until competition had been limited by the sale of most of the other mines to concerns which had need for all the coal they could produce and which, accordingly, would have no commercial coal for sale.

An Instance Pertinent to the Discussion

This case is quite important to this discussion for this reason: This company has about 6,000,000 tons of coal per year to sell. It is making a success of selling it over eighteen states. That being true, the sweeping decision is likely to be that a company with a tonnage of 6,000,000 annually can safely decide to sell its own coal over all of its own market, no matter how big that market may be. Before any such sweeping decision is made, I advise the coal men to take seriously into account the fact that this producing company is fortunately situated in that its principal competitors have been absorbed by steel mills and other companies which use all the coal they can produce. The conditions are so unusual they are not a safe criterion.

Even when a company is so fortunately situated, it is a big question whether it can afford to venture into the retailing field to market its own coal to any great extent. It will be well to examine the figures.

For easy figuring, we will say that the production of that field is now 20,000,000 tons per year. We will assume—which is not the case—that that entire production is controlled by one selling organization. That would mean that there would be about 8,000,000 tons a year available for distribution through retail yards. If we say that this coal is sold over eighteen states and that there are fifty counties in each state, that would mean that the mining organization would be required to maintain 900 retail yards in order to have but one yard in each county. This would give to each retail yard, so owned, a tonnage of but 6666 per year.

However, one retail yard cannot distribute coal over an entire county and succeed in competition with the

dozens of yards located in that county. If it could, the equipment necessary could not be supported on a tonnage of 6666 per year of one grade of coal.

Clearly, therefore, the unit control of even such an important field as Franklin County, Illinois, cannot, on the tonnage it produces, maintain retail yards in all the enormous markets.

Identically the same thing is true of the smokeless field of West Virginia and of all other individual coal fields the product of which travels over an extensive area.

Going back over the rather large field covered by this inquiry, several conclusions are obvious, namely:

The desire of the coal producer to retain control of his product through the stages of wholesaling and retailing is a natural ambition. It is an ambition which is commercially sound because it conforms to the efforts which have brought success to business men in other lines.

Before, however, the operator can hope even to enter the wholesale field, he must have a tonnage big enough to support his sales force in a big market. And this tonnage is most safely provided when the producer controls financially the mines which feed the central sales organization.

If an effort is made to extend the enterprise of the producer into the field of retailing, it is obviously true that he must have enough tonnage to support his retail yard. Also, he must have in his tonnage enough of a variety of coal to appeal to the trade in that district.

But, even granting that these exacting conditions have been fulfilled, the operator is not even then warranted in venturing into these other fields of action until, first, the business of wholesaling and of retailing has been made reasonably profitable. If the operator ventures before this is done, he may awaken to the fact that he has reinvested the money made in producing coal only to lose it in his marketing ventures.

Clearly, then, this question is so big the coal man dare not decide what to do without careful inquiry. I am inclined to advise caution, without, of course, advising against the effort as a whole.

Legal Department

MINE LESSEE'S RIGHTS IN SURFACE—A clause in a mine lease entitling the lessee to make use of the surface in removing the coal, ventilating, etc., conferred the right to drill a hole ten inches in diameter to release explosive gases which had accumulated above the coal in place, and which could not be removed by ventilation, especially where the presence of the gases endangered the mine and the safety of miners working therein. (Pennsylvania Supreme Court, Oberly vs. H. C. Frick Coke Co., 104 Atlantic Reporter, 864.)

RIGHT TO FORFEIT COAL LEASE—Ordinarily, courts will not declare a forfeiture of a coal-mining lease for breach of its terms, where there is no provision in the lease for forfeiture and where the lessor has a remedy by suit for damages. So, where a lessee paid the minimum royalty specified in his contract, mere failure on his part to remove coal expeditiously was not ground for forfeiting the lease. Nor will the fact that a mine is not worked as skillfully as it might be sustain suit to forfeit the lessee's rights, no substantial damage being entailed against the lessor. (Kentucky Court of Appeals, Haden vs. Continental Fuel Co., 206 Southwestern Reporter, 8.)

COMPUTING AWARD UNDER COMPENSATION ACT—Where a miner, injured by a fall of rock, suffered a fracture of the base of his skull, resulting in impairment of his sight and hearing and in dizziness, headaches and general disability, with a probability of permanent inability to resume his occupation of mining, it was proper, in computing an award to be paid him under the Colorado Workmen's Compensation Act to allow him on the basis of at least a 25 per cent. permanent disability, subject to modification on proof of his physical improvement. (Colorado Supreme Court, Employers' Mutual Insurance Co. vs. Industrial Commission of Colorado, 176 Pacific Reporter, 314.)

VIOLATION OF RULES BY EMPLOYEES—A mining rule adopted by an operator for the safety of his employees is subject to waiver or abandonment when not a statutory regulation. But, in any event, a mine employee's violation of a rule forbidding riding on tramcars cannot be regarded as the cause of his injury, through wheels of a tramcar passing over his foot, when it appears that the operator of the train saw the injured man's position and caused the accident by a sudden and negligent acceleration of the movement of the cars. Nor does the fact that the injured employee attempted to board the train while it was moving bar his right to recover for any injury attributable to such unexpected negligence of the operator of the cars. (Alabama Supreme Court, Bearden vs. Sloss-Sheffield Steel and Iron Co., 80 Southern Reporter, 42.)

VENTILATION IN KENTUCKY MINES—The Kentucky statutes require that breakthroughs between entries be made air-tight, as far as practicable, by brattices or otherwise, so that the current of air in circulation in the mine may sweep to the interior of the excavations where miners are at work. Held, that where a place of work of a mine laborer had been driven more than 60 feet beyond a breakthrough, and two of four breakthroughs controlling the air current at that place had not been bratticed, and others were insufficiently bratticed, there was a violation of the law, making the operator liable for injury to such laborer, caused by collision with a machine truck due to a dense smoke obscuring his lamp from sight at a point more than eight feet away. (Kentucky Court of Appeals, Elam vs. Hazard Coal Co., 205 Southwestern Reporter, 945.)

ACCIDENT AS EVIDENCE OF NEGLIGENCE—The fact that a miner is injured through a fall of rock at his place of work is of itself insufficient to raise a presumption of actionable negligence on the part of the employing operator. When an operator has discharged all of his common-law and statutory obligations concerning the safety of his employees, the latter assume the risk of injuries incident to their work. The Indiana statute, which places the burden on the operator to prove that he did not know of a danger resulting in injury to a miner in time to have prevented it, is satisfied by showing that the danger arose in the course of the work, although that fact be developed by testimony of witnesses for plaintiff in an action brought to recover damages for the injury. (Indiana Supreme Court, Snapp vs. Steinbaugh, 121 Northeastern Reporter, 81.)

POWERS OF BANKS—The Montgomery Coal Co., a retail coal company, being insolvent and indebted to defendant bank, it was agreed between them that the bank should buy sufficient fuel to supply the company's trade; the company's president acting as the bank's agent in retailing the same, and the net proceeds being applied to the company's indebtedness to the bank. The plan was put into execution and plaintiff, another creditor of the coal company, levied on coal which had been so purchased by the bank, on the theory that it belonged to the debtor coal company. Held, that although the contract may have been invalid as providing for business transactions beyond the scope of those objects for which the bank was incorporated, still the title to coal purchased by the bank under the arrangement was its property, and not subject to seizure as property of the coal company. (Texas Court of Civil Appeals, Spadra-Clarksville Coal Co. vs. Security National Bank of Dallas, 206 Southwestern Reporter, 200.)

Coal Industry Can Make More Use of Trade Acceptances

The successful outcome of the negotiations looking to the financing of the railroads until the required appropriations are made by Congress makes it certain that there will be no unusual delay in the payment of the railroads' fuel bills. The possibility that some months would pass, during which no money could be paid on coal accounts, has brought clearly to the attention of operators the advantages of the use of the trade acceptance. The Federal Reserve Board, since its foundation, has been urging the more extended use of this kind of commercial paper. Since this class of paper is readily acceptable at the Federal Reserve banks, it is being urged that the coal trade can make more generous use of it.

Fuel Administration Actively Engaged on Statistical Work

No change will be made in the conduct of the Fuel Administration at the end of the coal year. It will run along as at present until July 1, it is expected. The work on records and statistics now constitutes the Administration's principal activity. Dr. Garfield continues to spend practically all of his time in Washington and will do so until after the Easter vacations, at which time it is understood he will give a larger portion of his time to his educational work.

New Railroad Appointees Meet with Approval of Coal Men

Announcement of the appointment of Swagar Sherley as director of the division of finance of the Railroad Administration meets with much favor among the representatives of the coal industry in Washington. Mr. Sherley is from a coal-producing state and, as chairman of the appropriations committee of the House of Representatives, has been in close touch with the public's viewpoint as to the railroad fuel question. It is regarded as highly improbable that Mr. Sherley will stand for a policy which will allow the railroads to foist a portion of their fuel bills onto other consumers. Mr. Sherley has represented the fifth Kentucky district in Congress since 1903.

Coal men generally, judging from advices reaching here, are convinced that John Skelton Williams, who has had charge of finance and purchases, was entirely out of sympathy with the principles advocated by coal producers in the matter of purchasing railroad fuel. His resignation came as a decided relief to the representatives in Washington of the coal industry who foresaw a continuance of difficult situations if Mr. Williams remained in office.

Under the new order, separate divisions have been created. Finance and Purchases each has a separate status. Henry B. Spencer is to head the Division of Purchases. He also is highly acceptable to the coal industry. He formerly was president of the Railway Fuel Co., which operated in Alabama. He has been in charge of the Railroad Administration's end of the conferences with the National Coal Association with regard to railroad fuel. He is given credit for having made possible the satisfactory results which came from those conferences.

Mr. Spencer is a native of Long Branch, N. J. He was graduated from Harvard University in 1895. Most of his career has been spent in the service of the Southern Railway. He rose from a humble position in the operating service of that system to be successively its general manager, vice-president and a member of its board of directors.

Demurrage Rates Cut by Federal Railroad Administration

A cut of $1 per day in demurrage rates and a recommendation to shippers to continue their shipments to the Tidewater Coal Exchange during March was the outcome of the first meeting held by the committee of operators, wholesalers, tradesmen and consumers appointed at the meeting held in Washington on Feb. 14, with the committee representing the Federal Railroad Administration. The meeting took place in Washington on Thursday of the last week in February and it was announced that the demurrage rates would be reduced from $3 to $2 per day for this month at the ports involved—New York, Philadelphia, Baltimore and Hampton Roads, and that it would be recommended that all shippers continue their shipments to the Tidewater Coal Exchange during the month. In the meantime further consideration will be given the matter, and it is expected another meeting of the joint committees will take place in March.

Consumption Records Prove of Value to Large Users of Coal

When the large consumers of coal first were called on by the Fuel Administration to make a return on the amount of coal being used, there was some protest. This was based principally on the assertion that it would be too difficult to keep account of the exact amount of coal burned. After having made the report for seven

months, however, many consumers have found the information of such value to themselves that they will continue to measure the coal burned. One of the largest consumers, in a recent letter to the Fuel Administration, says the cost and trouble of securing the information is negligible, when compared with the saving in fuel consumed. That company has ordered the report continued for its own use.

During the seven months that the consumers' reports were required, the cards containing the information, if piled in a single stack, would be twice the height of the Washington monument, one of the Administration's statisticians has calculated.

National Coal Association Sending Out a Questionnaire on Demurrage Rules

Announcement by the American Railroad Association that its national car demurrage rules are being revised has led the National Coal Association to send out a questionnaire through the local associations. Operators and others interested are asked to indicate whether they desire that the mine rating and car distribution rules of the Railroad Administration should apply during times of car surpluses, as well as during times of car shortage; whether demurrage should be assessed on unbilled loads held on mine tracks and whether they regard it as advisable for the National Coal Association to exert every effort to carry out their will in the foregoing propositions, even to the point of filing a complaint with the Interstate Commerce Commission.

Will Reduce Transportation Rates to Help American Foreign Trade

Exporters of coal soon are to enjoy much lower transportation rates. The cut is to apply to the rail haul to ports as well as to the ocean carriage. This is a part of a plan, affecting all exportable commodities, which is being perfected by the Railroad Administration and the United States Shipping Board to aid American industries to extend foreign trade. The reduced rates will apply to all the more important ports of the Atlantic, Gulf and Pacific. The State Department and the Department of Commerce are coöperating with the Railroad Administration and the Shipping Board to work out plans best suited to meeting foreign competition.

New Chairman of Mining Committee of House of Representatives

Mahlon M. Garland, who has been selected by the Republican Committee on Committees, to be chairman of the Mines and Mining Committee of the House of Representatives, has spent his entire life in close contact with the coal-mining industry in his native state of Pennsylvania. Through his association with labor movements he has been brought in frequent touch with other classes of mining. He is the ranking Republican member of the Committee on Mines and Mining and has taken part in the handling of bills pertaining to mining during the ten years he has been in Congress. Mr. Garland formerly was vice president of the American Federation of Labor. From 1892 to 1898 he was president of the Amalgamated Association of Iron, Steel and Tin Workers.

Anthracite Shipments for February

The anthracite shipments for February as reported to the Anthracite Bureau of Information, Philadelphia, amounted to 3,871,932 tons, this being, with exception of the strike years, 1902, 1906 and 1912, the smallest in a period of eighteen years, or since December, 1901.

As compared with the preceding month, when the shipments were 5,934,241 tons, the shipments in February showed a decrease of a little over two million tons, while as compared with February of last year the shipments showed a decrease of 1,940,000 tons.

The very low record for February of this year may be attributed to the exceptionally mild weather which has prevailed during the entire winter. The shipments by companies were as follows:

	February, 1919	February, 1918	Coal Year, 1918–1919	Coal Year, 1917–1918
P. & R. Ry.	725,809	1,107,982	13,359,828	13,459,445
L. V. R.R.	643,551	1,042,784	12,586,368	12,865,850
C. R.R. of N. J.	334,697	526,292	5,928,059	6,249,024
D. L. & W. R.R.	597,604	997,550	10,233,528	11,372,936
D. & H. Co.	629,929	600,799	8,162,731	7,892,860
Penna. R.R.	272,031	459,271	4,755,812	5,123,695
Erie R.R.	371,033	614,210	7,588,336	7,975,611
N. Y. O. & W. Ry.	108,029	177,047	1,749,351	1,865,556
L. & N. E. R.R.	188,249	286,147	3,384,836	3,670,561
Total	3,871,932	5,812,082	67,728,849	70,475,538

Will Take American People Twenty-Five Years to Pay Off War Debt

It will cost the American people about $1,200,000,000 a year for the next 25 years to pay off the war debt, according to estimates of the Treasury. The calculation is made on the assumption that the net war debt, with deductions for loans to the Allies, will be in the neighborhood of $18,000,000,000.

Interest on this amount, at the rate of 4¼ per cent., would be $765,000,000 a year, to be raised by taxes, and then repaid to bondholders. In addition, about $417,000,000 would have to be provided every year as a sinking fund to redeem all bonds in 25 years.

This would require a cumulative sinking fund provision of 2.32 per cent. Congress has not yet authorized establishment of a sinking fund as recommended by Secretary Glass.

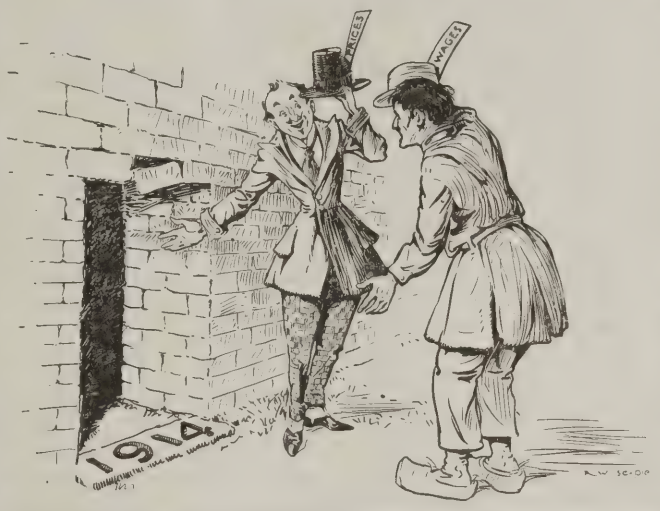
New Chairman of Mining Committee House of Representatives

Of late there has been much interest manifested in the use of more up-to-date mining machinery in the coal mines of New Zealand in the interest of the health of the miners, since the dust evil was becoming quite a serious item and miners were objecting to work unless something was done to better the conditions.

The minister of mines agreed that everything possible should be done to minimize the loss of life, and it seems that something definite will be done to introduce the best up-to-date drilling machinery as well as other preventive means.

A special rock drill is now on trial in some of the mines, but as yet it has not proved satisfactory, but additional trials are to be made.

The coal mines of the country have been operated at fair profits during the past three years, but have fallen far short of supplying the demands of the Dominion.



Representatives of the coal trade in the Baltimore region are planning a banquet to be held about Mar. 21.

EDITORIALS

Touching Faith of Wage Reductionists

WITH accord of word and unison of voice the wage reductionists urge that wages must (and will) come down with prices. But if prices will not come down first, if prices depend on wages, which stay up, what happens then, wise wage reductionists? If wages and prices bow to one another and say, "After you, my dear Alphonse," nothing will be done to make either stoop to their lower level in 1914.

There are profiteering prices, of course, and these can be clipped; but large reductions cannot be looked for till wages have dropped. As long as Alphonse waits on Gaston, and Gaston on Alphonse, there will be nothing done. Why should either scramble through the scuttle-way at the bidding of the consumer?

GASTON (Prices) to Alphonse (Wages): After you, my dear Alphonse.
If they continue polite they will never re-enter the low portal of 1914.

As for the coal industry participating in a general reduction of prices and wages, it may be well to recall that the industry is now well organized. It seems quite possible that without violating any agreement the anthracite operators could make a new and lower contract as soon as the war is over; and it is certain that the bituminous operators could do so also—but what of it? They won't do it. The mine workers would not permit of it, to begin with. There is not enough labor, free of the unions, to make the unions consent to a reduction, and prices have not come down enough to justify such a lowering of wages.

Short-time work is sufficiently trying to the mine worker without having a short day-rate or a short tonnage schedule to make the sustenance of life impossible. For these and general reasons the operators are heartily out of accord, as far as all signs go, with the suggestion that they should cut hours and schedules at the same time. It is enough to strike down the mine worker with the club of short days. By all means, spare him a blow with the cudgel of short pay. He could hardly survive them both.

But some suggest that anthracite wages must come down before that fuel can hold its own in the market in competition with bituminous coal. In this regard the anthracite industry has occasionally had qualms of fear. As regards competition in small sizes that fear is now, as in all normal times, well justified; especially now that the consumers of bituminous coal have been emboldened by the recent laxity of municipal inspectors. These functionaries are not studying Ringelmann's charts with the old-time assiduity, to judge by the grayness of the skyline of most of our large cities. But now that anthracite is getting plentiful the public will begin to bring pressure for the use of smokeless coal or, at least, for the smokeless consumption of such coal as is naturally smoky.

Some anthracite operators are afraid also of coke, near-coke and gas, all of which are actively pushing, as the case may be, to a place, or a larger place, in the domestic trade. But all three are being made from bituminous coal, which has lately become increasingly expensive, and competition is consequently not so fierce as might be feared. The sale of coke and near-coke threatens the anthracite industry not more, but rather less, than before, because owing to the increase in wage rates bituminous coal has risen in price more than anthracite. As for gas, that has more nearly remained stationary; but the stability has been due largely to franchise restrictions and the control exercised by public-service commissions. Time will see a lifting of those conditions. Certainly the gas men are not advocating cheaper gas but trying to put the price higher in order to restore their failing dividends. If anthracite proves later in the year to be in short quantity, then there will be no reason for anthracite men to cut wages and reduce prices. If anthracite continues in excessive supply—the notion seems ridiculous—then the natural thing will be to keep the wage scale and shut down the unprofitable mines rather than award the mine worker low wages and short time.

As a rule wages fall first and prices afterward, or both fall together, for no considerable price reduction can come without a wage decrease, the profits in an industry being rarely comparable in any way with wages. This is why a wage increase in all the trades employed by an industry can almost never be absorbed by the industry without inevitable bankruptcy. Certain it is that most anthracite men, especially in the southern anthracite field, are not so placed that they can help in the general price reduction for which the wage reductionists so fervently pray and so confidently hope.

The automobilist, by the use of goggles, guards his eyes from dust. The miner has, so far, not seen fit to do so in his dusty work underground, though the occasion is at least equal. Such goggles should be fitted so as to help vision and should only be of plain glass when protecting perfectly normal eyes. Many a short- or long-sighted man who would wear such prescribed goggles would never thereafter go back to a life made burdensome by the deficiencies of his unaided vision.

Mine Inspectors' Institute of the United States of America

AT THE close of the Joplin (Mo.) annual meeting of the Mine Inspectors' Institute, June 13-15, 1916, it was decided to hold the next meeting, which would be the decennial meeting of the Institute, at the place of its organization (June, 1908), Indianapolis, Ind. The constitution was amended, making the time for holding the annual meeting, thereafter, the second Tuesday in July, instead of the second Tuesday in June, as previously.

Before the time arrived for holding that meeting, however, the imminent prospect of this country entering the European war decided the Executive Committee of the Institute to postpone further meetings until conditions resumed a more nearly normal state and the duties of mine inspectors would permit of their temporary absence from home.

July of the following year (1918) afforded no improvement, and the increase in war activities left no opportunity for inspectors of mines to get away, if it was only for a day. The urgent demand for an increased production of coal, together with the employment of many unacquainted with mining conditions, required the constant watchcare of every inspector.

The war is now over and conditions in the mines are rapidly assuming their normal aspect. The year 1919 should find the mine inspectors from every state and the provinces of Canada gather in July at the old stamping ground, in Indianapolis, to greet each other and confer on the many questions of growing importance in the coal industry.

There have been many changes in the mine inspection departments of the different states, and inspectors who are not already members of the organization should address the secretary, James W. Paul, Bureau of Mines, Pittsburgh, Penn., for application blanks. On request, *Coal Age* will send copies of the last report of the Institute, gratis. Let every member take an active interest in securing new members, and making certain his own presence at Indianapolis July 8-11, 1919. Let every state department and governor see that delegates from their own states are in attendance.

When technical men are gathered together, a so-called practical man usually wanders in and has something true, but uncharitable, to say about engineers' estimates, from which it appears that the engineer knows as little about costs of construction as the practical man knows about costs of production; and that an engineer's forecast is as defective as the operator's vision of what is right before his eyes.

The New England Problem

NEW ENGLAND, because of its geographical position and concentrated business activity, has always been the greatest problem of the coal industry. To keep this small but highly congested industrial section adequately supplied with fuel throughout the whole twelve months, even to the detriment of the just and deserving demands of other parts of the country, has been particularly trying during the past few years. It not only worried the Administration quite a little last winter, but threatened to become a most serious problem of national significance. Fortunately it was overcome before the deluge came.

Roughly estimated, New England consumes thirty million tons of coal annually, one-third of which comes all-rail and the rest by tidewater. It is a physical impossibility to increase the rail shipments by any substantial amounts, so any increased tonnage must be supplied by the water route. While it is true that New England enters this year with a larger stock on hand, perhaps, than any year before in her history, it is also true that the current receipts of both rail coal and tide, particularly the latter, have been so far below normal the past three months that the one condition is offset by the other. Should the current receipts keep falling below the usual monthly quota a few months more—and all indications point that way—the problem of furnishing New England with her adequate supply of coal will again become one of serious consideration.

The problem will probably be of a more local nature this time, because the crux of the matter lies in the discharging facilities of the New England ports and not because of a possible shortage of coal or ships. There is a maximum limit to the tonnage that can be discharged at these ports, and while their present facilities are such that twenty million tons of coal can readily be handled, the task can only be accomplished by being spread evenly over the entire year. The job cannot be done in a few months, or six, or even more perhaps. Trying to do so last year showed plainly that it was not feasible or wise. Had New England industries been actually dependent upon the current requirements they then claimed were needed to keep running, and had not had on hand stocks of coal which were measured through the wrong end of a telescope, this impossibility would have been more clearly and painfully demonstrated.

As seems quite natural, New England consumers have been holding off in their buying of coal in the expectation that coal prices and water freights would be reduced. Meantime they are making all efforts to use up what poor coal they had left in their stock piles. While this is quite a logical procedure, it nevertheless has upset the regular clockwork-like arrangement by which New England is harmoniously supplied with fuel. The machinery has been thrown out of gear, and trouble, more or less serious, is bound to come of it. It is unlikely that the rest of the country will also suffer with New England in her possible difficulties this year, providing the other sections will not carry the "watchful waiting" policy too far also, although there may be a temporary interference in the regular flow of coal.

Of more than passing interest, therefore, will be the attitude New England consumers manifest during the next two months toward replenishing their diminishing stock piles and in preparing for the coming winter.

Governor Sproul of Pennsylvania says that after a mild winter, like that just experienced, the prices of anthracite should not be increased. The public, in general, when worried by the large coal bills of arctic winters, says anthracite should not go up in price when the demand for it makes such a large consumption of that fuel necessary. Any reason is enough as basis for the contention that anthracite should be sold below cost, and it will satisfy almost any one but the anthracite producers and those few old-fashioned people who still hanker after justice for everyone.

THE LABOR SITUATION

General Labor Review

Lacking steady work, all kinds of evils arise to trouble the waters, and the only way to cure them is to remove the source and not to apply emollients of doubtful value. When once we again get a demand for coal the problem of keeping idle miners at work will be solved. Let the operator keep this fact in mind. He is apt to think that his chief hope is in parsimony, in restricting tax levies and in preaching caution. It is not so. His hope lies not there, but in encouraging national expenditure, and in inducing states and municipalities to expend money in permanent improvements. Then the wheels will turn and the very heat of the mechanism will keep it from freezing, and its very movement will prevent it from corroding.

Always the basal infirmity is the one to be corrected. Medicine is forever alleviating the symptom and overlooking the real cause of ailment. Our policy at the mines is the same. The six-hour day can be met only by offering the possibility of steady work with the eight-hour day and we can only do this by proper political action.

Our cartoonist has produced this week a poster of merit, but it is clear that the workman will say that for six hours he should demand the pay granted for eight. That being allowed to the workman, the price of everything would go up 33 per cent. It is difficult for any one to understand that a defense taken by one man becomes no defense if used by all. The gas attack helped the Germans till the Allies used it. The six-hour day will help the mine worker admirably till the shoemaker, the baker and the butcher use it.

Hence it is that a six-hour day is to be combated. The workman wants his standard of living maintained and will make trouble if he does not get it. The only way he can make that standard possible is by working a full day. It would be a wrong to let him reduce the means by which alone his standard of living can be maintained.

Umpire Neill Delivers Two Decisions

Charles P. Neill, the umpire of the Anthracite Conciliation Board, has given two decisions, one recognizing the rights of the employers and another the rights of the employees. The engineers, firemen and cranesmen, engaged on the steam shovels in the Jeddo stripping, of the G. B. Markle Co., believed themselves to be of such a class as to be entitled to the eight-hour day with a three per cent. increase. They had been given by the company a flat seven per cent. increase on the basis of a nine-hour day. The shorter day, though accompanied by a smaller increase in wage, made the wage increase per hour 16 per cent. instead of seven per cent., which would be all they would get if nine hours constituted a day's work.

The change is a basal one. The revisions made recently do not modify it. It modifies the wage schedule way back to May 5, 1916, and being retroactive will provide for a payment of thousands of dollars. The decision was made on March 11.

The decision which has been mentioned as made against the employees was rendered in reference to the operation of the Dunmore vein at the Diamond Colliery of the Delaware, Lackawanna, and Western R.R., Coal Department. The gangway miners declared that the charge for lifting bottom rock was $3.60 per lineal yard regardless of its thickness. This rock usually runs from 44 to 48 in. thick. The company contended that the rate was eight cents per inch, the $3.60 being evidently based on a thickness of 45 inches.

Glen White Shooting Affray in Court

A crowd that taxed the capacity of the circuit court room in Beckley, W. Va., was present Mar. 8 for the hearing then to be given the twelve men charged with complicity in the Glen White shooting affray. Just as the stage was set to proceed with the inquiry, attorneys of the accused men announced that their clients would waive examination, and all were placed under bond to appear at the next term of criminal court.

The men under arrest are James R. Gilmore, president of the United Mine Workers of District No. 29; Lawrence Dwyer, international board member; Obe Clendenin and Toney Stafford, district board members; Ed. Snyder, Toney Sarazzo, Will Owen, Tom Murphy, George Lucas, Tom McGinnis, Dorr Snuffer, and Tom Lethco.

All are charged with complicity in a shooting affray that took place at Glen White on Nov. 16, 1917, at a time when there was trouble between the E. E. White Coal Co. and a part of its working force. Eight of the twelve accused men are alleged to have been active participants in the shooting and the other four—Gilmore, Dwyer, Clendenin and Snyder—are held as accessories before the act.

Increase Is Not Based on Quality of Work

Special Umpire Allison O. Smith, of Clearfield, Penn., sitting in Charleston as a judge of disputes between the miners and operators of the New River and Winding Gulf fields, has handed down decisions in three cases which will be of much interest to the operators in those districts. Two of the decisions sustained the contentions of the men and the third was favorable to the operators.

The first decision was in the case of B. F. Tarleton vs. the New River Coal Co. The facts brought out in this case were that Tarleton accepted work at the Summerlee mine as engineer in the month of May, 1918. He was paid $105 per month, which he claimed was not the proper wage for that job. He based his contention on the fact that the man who was performing that work during October, 1917, was paid $85 per month. The Washington award of $1.40 per day would make the proper wage for that employment for the months that had 30 days, $127.00, and for the months that had 31 days, $128.40. For this reason Tarleton asked that the company be directed to pay him the shortage in his pay envelope during the whole period of his employment.

The judge's decision sustained Tarleton's claim, and ordered that he be paid the difference between the $105.00 and $127.00 or $128.40 per month for which the contract called. The judge remarked that the advance figured out in the production of coal was figured at what the job was paid prior to the granting of the advance. Therefore, it was his decision that, as long as the operating company received the extra 45c. in the selling price of coal, it should pay the advances that the increase was based on.

In the case of Warren Sizemore vs. the Coal Run mine, Sizemore claimed he was discriminated against and discharged for belonging to the union, and he asked that he be compensated for 18 days, the time he was idle on account of his discharge. Judge Smith sustained this claim and directed that the company pay Sizemore for the 18 days' idleness at the rate of $4 per day.

In a car-pushing case the judge's decision sustained the operators. A voluminous amount of evidence was presented by both sides, the operators contending that the 10c. differential paid in the mines on the New River was paid to the men to compensate for car pushing, while the miners contended that it was paid on account of the low coal.

The judge pointed out that the evidence of both the miners and operators was that this 10c. was given years ago. Though the miners testified that it was their understanding that it was paid on account of the lowness of the coal, but none of them could give positive evidence.

On the other hand the operators presented the evidence of Mr. Beury and Mr. Caperton, who had been operating coal at the time. They were able to testify that they knew just why the differential was granted.

Judge Smith ordered that this decision should in no way change any of the present customs throughout the field, that where men are paid for the pushing of cars or tracklaying they shall continue to be paid; and that in cases where the pushing of cars over long distances or over extra steep grades is necessary, the miners have the right to take such cases up as grievances.

British Columbian Miners Exhibit Excellent Judgment

One of the important questions discussed at the recent annual convention of District 18, United Mine Workers of America, was the renewal of agreements. One of these, that between the miners and the management of the Crow's Nest Pass Coal Co., Fernie, B. C., being due to expire on Mar. 31. It was announced, in this connection, that a policy committee meeting would be held at Indianapolis on Mar. 18, which would be attended by representatives of all districts. It was decided, therefore, that the operators should be approached with a view to arranging for an extension of the present contract, modified, of course, as has recently been provided, by the awards of the commission on cost of living. This was agreed upon in order that the demands of District 18 could be made to conform, in some degree, with those of the miners of the United States and possibly those of Great Britain. Representatives appointed to represent the district at this meeting are: P. M. Christopher, district president; Robert Livett, international board member; Frank Wheatley and Alex. Susnar. International Organizer David Rees also will attend. These delegates were instructed to indorse the proposals contained in a circular by Frank Farrington, president of the Illinois miners, for a six-hour day and a five-day week.

In the conference with the operators, which took place subsequently, Fuel Director W. H. Armstrong presided and the utmost good feeling prevailed. The operators agreed to postpone negotiations pending the meeting of the policy committee, and a further meeting with the operators is to be arranged as soon as possible after the return of the District 18 representatives.

Two noteworthy changes made in the constitution of District 18 by the Convention were that conventions and elections of officers should be held biennially instead of annually.

Mine Workers Attack Girard Royalties

The mine workers in the anthracite region are getting official recognition of their attacks on the operators' practice of closing mines which are not being profitably operated. Their executive board in the Hazelton district has decided to make a request for a tridistrict convention of the men of the anthracite field. This meeting is to be held, if the board gets its way, about the middle of August.

It will frame new demands to be presented to the anthracite operators when the basic agreement expires in April, 1920, till which time the mine workers are not at liberty to change the scale, though it would appear that the operators could change it, if they would, at any time after the signing of the peace without becoming subject to a charge of violating their agreement.

However, everybody concedes that the scale will remain unchanged till April, 1920, when the mine workers will probably make some demands, if the will of the international convention that will meet in September of this year is favorable to changes. Among the demands will possibly be the one just mentioned. The shutting down of unprofitable mines has been quite a general practice of late, and the dispossessed mine workers are determined that the equal turn shall apply not only as to single mines but as to all the mines of one company. The desired rule is not to be commended on general principles. The nation is not helped by the operation of inefficient mines.

The required output should come by working briskly the most suitable mines having regard to ease of working, quality of coal and propinquity to market. The Kansas men have sought in the past a like restriction of the option to close unprofitable mines. The idea is, therefore, not new. In fact the anthracite miner has less to complain about than some other mine workers, for in other states work is far less steady, there is less other work, and, the mines being further apart, moving is more of a problem and commuting to work not possible.

No one can help, however, growing a little angry about the predicament of the mine workers of the Lehigh Valley Coal Co. who are laid idle by reason of the high royalties charged by the Stephen Girard Estate. Strange to say the trustees of that estate do not seem to realize how improper are the charges they are making for coal in the bed. One trustee actually ventured some time ago to criticize the conduct of the anthracite operators and question their prices. His criticisms furnished the basis for an informal indictment of the anthracite industry made a few years ago in the Brooklyn City Hall.

The royalty collectors have an air of self-satisfied pride when they point to the profits, real and imaginary, in coal mining, but for this there is no justification whatever, the holding of coal land being of no benefit to the public, whereas the mining of coal is of benefit, yet in the anthracite region the holding of coal has been the source of larger profit. The mine workers are not without knowledge of the true conditions, and, on Mar. 13, the mine workers' officials made the following statement:

"We find that the Girard estate is more responsible for the shutdown than the coal company, for the high cost of the coal at the mines shut down is due to the large royalty charged the Lehigh Valley and to other coal companies operating colleries on the estate. We are reliably informed that the estate is charging a royalty of from $1.05 to $1.22 per ton on all sizes of coal, and that it has a sliding scale which is raised according to the price at which the coal is sold.

"From the rich fields of coal in Schuylkill County the estate has reaped a great harvest of wealth in the obtaining of which the poor miner has been hardly dealt with. The miners have had their homes badly damaged by the mine operations. These homes have, in many cases, been made untenable. Miners have labored all their lives to develop the rich deposits on the estate, the wealth of which is spent in Philadelphia and other places. Little consideration has been shown to the poor mine worker who has produced enormous wealth for this heartless estate.

"In the opinion of the miners, Stephen Girard never intended in his will to discriminate in such a manner against the producer of the valuable mineral on his estate, the value of which he did not realize though he commenced to mine it before he died.

"We would ask the State Legislature to take notice of the conduct and management of this estate, and look into this matter of big royalties which prevent tenants from working steadily and have caused a general shutdown in part of the anthracite region, causing suffering to thousands of mine workers and their families."

A complete tie-up of all mines of the Delaware, Lackawanna & Western R.R. Co. Coal Department is threatened unless the company agrees to the demands of the miners for a more equitable distribution of work at its collieries. If the demands of the men are not granted more than ten thousand mine workers may strike.

Some weeks ago the D. L. & W. R.R. Co. shut down several mines because of there being no demand for coal, and thousands of men were thrown out of work. Those who are idle claim that the company is hiring men from outside districts to operate the mines that are working and is refusing to hire men who are out of work as a result of the shutdown.

Sure, the Full Day and the Whole Dollar Have Always Been Friends

A Short Day Means a Short Dollar

What we don't dig out of the ground or manufacture we'll never have. That's a cinch. We're having short running time this year and it's going to cut in on our comforts. We all know that short running time makes hard sledding for the miner. A short working day, as a permanent institution for everybody everywhere, would do the same for everybody and for ever unless we could somehow contrive to do as much in the short day as we have been in the habit of doing in the long day.

Discussion by Readers

Waste of Coal

Letter No. 3—I was glad to read the letter of Russell Exline, *Coal Age*, Dec. 26, p. 1176, which drew my attention to a previous article that I had missed and which showed that the annual waste of coal, in this country, was equal to a solid cube 1785 ft. on a side and containing 150,000,000 tons. It was not stated whether this waste occurs in the mine or after the coal is taken to the surface.

However, let me ask, Does it ever occur to coal operators how much coal is wasted and lost beyond recovery in their mines? An operator buys or leases a tract of land, in the latter case paying the owner a fixed price per ton of coal mined and brought to the surface. In either case, the cheapest coal is extracted first, and that which can only be secured at a much higher cost is left and, perhaps, never recovered.

If my information is correct it is not the custom, in the British Isles, to lease coal land at an agreed price per ton of coal mined. The prevailing custom is to lease a tract of land on the basis of an estimated tonnage, per foot-acre, which required the operator to pay a fixed price for the coal whether or not the estimated tonnage was mined.

Much waste occurs by reason of the method of mining adopted. Longwall mining involves a less loss of coal than any other method and affords good ventilation at the working face. There are no pillars to be drawn, all the coal being taken out in the first working. I recall an instance of my boyhood, in Scotland, where a coal seam 5 ft. in thickness was worked by longwall and the operator was obliged to secure sandstone rock from a near-by quarry, for the purpose of building the packwalls in the mine. The rock was sent down into the mine every night.

In many coal mines, today, coal is blasted off the solid and it is safe to say that a considerable percentage of this coal is thrown into the gob and lost. The practice is both dangerous to life and wasteful and should be prohibited by a law that would require every shot to be undermined before the coal is blasted.

Wasteful Methods in Machine Mining

Where the coal is mined by machines, more or less of it is wasted, according to the type of machine employed. When the mining is done in the clay underlying the coal, which is usually the case where the puncher type of coal cutter is used, very little of the coal is wasted. The puncher machine is mostly operated by air and, in that event, has the advantage over electric coal cutters for working wet places going to the dip. When such places are worked with electric machines, it is often necessary to leave several inches of coal on the bottom.

It is customary for a superintendent, in placing an order for electric coal cutters, to specify that they must cut coal 4 in. or less from the bottom. In some cases, the cut is made higher up in the seam and the bottom coal is then lifted later, the machineman paying the digger for that work. With some types of electric chain cutters, it takes an expert machine runner to cut the coal less than 4 in. from the bottom. It can be done with the ironclad Sullivan machine, but it takes time and is a disadvantage where the machinemen are paid by the ton.

Machine runners seldom stop to consider how much coal is wasted when 4 or 5 in. of bottom coal is left, in cutting a room 25 ft. wide and 300 ft. long. Taking the weight of the coal as 80 lb. per cu,ft., the amount of coal left in 4 in. of bottom is $\frac{1}{3}(300 \times 25)80 \div 2000 = 100$ tons. The loss of 4 in. of bottom coal, in mining out 1 sq.mi., would mean the loss of over 370,000 tons.

Again, when pillars are being drawn, miners are frequently allowed to take a skip off the rib, with the result that a cave occurs that overrides much of the pillars still remaining, and it is not uncommon for 100 or 200 tons of coal to be thus lost in a single pillar.

Pillars should always be drawn with a straight face across the pillar, at right angles to the track, so that the break will not injure the pillar by causing the pressure to override and crush the coal remaining. Pillar coal is often lost by reason of timbers left standing in the gob, which prevents the settlement of the roof and throws the weight forward on the pillar.

Notwithstanding the fact that there is sufficient coal in the United States to last for two or three thousand years, it is a shame to see the unwarranted waste that occurs in the mining of coal today. The time will come when coal will be scarce and difficult to mine. Let us strive to conserve this natural supply of fuel.

———, Colo. FOREMAN.

Firebosses as State Officials

Letter No. 1—In arguing the question of attaining the highest efficiency in firebossing, recently, it has been claimed that this can be best attained by placing the fireboss under the jurisdiction of the state. I am not in favor of firebosses being employed by the state; nor do I think that they should be considered in any other capacity than that of a *mine examiner*, whose duty is not only to examine the mine for gas but to discover any other dangers that may arise on the roads, travelingways or working places of the mine.

Miners are exposed to a great variety of dangers, many of which require constant watch and a very close inspection, in order to detect them before an accident occurs. If we are anxious to protect the lives of miners and make the mining of coal more safe a law should be enacted in every coal-producing state that would make it necessary for each mine to employ one or more local mine examiners.

These men should be in the mine during the entire day and devote their time to a close inspection of each working place and give such instructions to the men as would make their work more safe. It is my belief

that many men are killed every day, in coal mines, because of lack of proper instruction in regard to safe methods of performing their work.

Speaking of the employment of firebosses, by the state, I fail to see what benefit would arise by so doing. It has been suggested that when acting under state authority, the fireboss would be held in higher regard by the mine foreman who would fear to go contrary to his orders or to operate the mine in any way that would not comply with the state mining law. My own idea, in this respect, is that it would make little difference with the mine foreman, except to increase his dislike of being compelled to obey the orders of the fireboss, and the natural result would be that many foremen would be disposed to make life miserable for the fireboss, by entering complaints against him to the deputy mine inspector, who would be compelled to make constant investigations to ascertain the true situation of affairs in the mine.

The employment of firebosses by the state would, in my opinion, be very apt to raise some questions in regard to the liability of the state in the compensation for accidents occurring in mines. It would certainly have a tendency to raise the standard of qualifications for the position of fireboss. That being the case, many of the men now holding that position would be found incompetent and their certificates revoked.

Taking everything into consideration, therefore, it is my belief that the opinion of the large majority of practical mining men who have held positions as fireboss, assistant foreman and foreman, in coal mines, if candidly expressed, would be opposed to the suggestion of the employment of firebosses by the state. Let us hear what arguments can be advanced for and against this proposition. ROBERT A. MARSHALL.

Farr, Colo.

Engine-Plane Haulage

Letter No. 1—Kindly permit me to suggest two solutions to the engine-plane problem presented in *Coal Age*, Feb. 6, p. 293. As there explained, an incline 400 ft. long and having a grade of 25 per cent. leads from the tipple to a point in the mine entry where the grade suddenly changes to 1½ per cent. and continues at that for a distance of 1000 ft., to the inside parting where the trips are made up to be hauled out of the mine.

My first suggestion, however, will not be practicable, unless the output of the mine exceeds 500 tons per day, as the expense would hardly be warranted for a less tonnage. It is to construct a trestle and drive a new slope leading from the tipple to the side track in the mine and having a uniform grade throughout. But, for the reason just stated, we will leave this suggestion without further remark.

My second suggestion assumes that no change is to be made in the grades given. My plan, now, would be to estimate on a tonnage 50 per cent. greater than that stated, or say 750 tons per day, which will provide against all contingencies. In order to haul longer trips at a reasonably low speed, I would use a duplex second-motion engine, geared about 4 to 1. By the use of the common formulas, I would calculate the size of engine required to haul loaded trips of 10 cars each, basing this calculation on the maximum grade of 25 per cent., or an inclination of about 14 degrees.

The weight of coal hauled in a single trip is $10(5000 - 1500) \div 2000 = 17.5$ tons, and to put out 750 tons in a day of 8 hours will require $750 \div 17.5 =$ say 43 trips. The time of making one round trip is, therefore, $(8 \times 60) \div 43 = 11.16$ min. Then, allowing 2 min. for changing ropes at each end gives for the actual running time slightly more than 7 min. The total distance covered in this time is $2 \times 1400 = 2800$ ft., which makes the average speed of hauling $2800 \div 7 = 400$ ft. per minute.

In practice, the speed of hauling would be somewhat greater than the average on the lesser grade and considerably less when hauling up the incline. Thus, on the 1½ per cent. grade, the speed of hauling might vary from 500 to 600 ft. per min., while on the incline it might average 250 ft. per minute.

Suggests Installing a Tail-Rope System

Allow me to suggest, here, that a modified tail-rope system of haulage strikes me as being best adapted to the conditions in this mine. For example, I would use a ¾-in., crucible-steel wire rope for both the main and tail rope. This rope will weigh 0.88 lb. per ft. Starting from the side track in the mine, the main rope hauls the loaded trip out to the foot of the incline, dragging behind it the tail rope, which is attached to the rear end of the trip. At the foot of the incline the tail rope is detached from the trip and left lying in the road, while the main rope pulls the trip up the incline. The weight of the rope resting on the incline is $400 \times 0.88 = 352$ lb., while the weight of the loaded trip is $10 \times 5000 = 50{,}000$ lb., which makes the total moving load when the trip is at the foot of the incline 50,352 pounds.

Now, for a 25 per cent. grade, the sine of the angle of inclination is 0.24249 and the cosine, 0.97015. Then, assuming a track resistance of 20 lb. per ton, the total load on the rope at the head of the incline when a loaded trip is starting to ascend is

$$L = 50{,}352\left(0.24249 + \frac{0.97015}{100}\right) = \text{say } 13{,}000\ lb.$$

Finally, estimating the power of the engine that will haul this load at the average speed previously calculated, we have, allowing 80 per cent. as the efficiency of the engine,

$$H = \frac{13{,}000 \times 400}{0.80 \times 33{,}000} = \text{say } 200\ hp.$$

Returning, when the empty trip has been lowered to the foot of the incline, the tail rope lying there is attached to the head end of the trip and assists in pulling the empties back into the mine. Let me say, here, that in making such estimates it is always a good plan to submit the proposition to manufacturers of haulage and hoisting equipment in mines and receive from them their bids on plans that they consider adapted to meet the requirements. STEVE GOSNELL.

Hallidayboro, Ill.

Letter No. 2—Interest has been aroused here by the inquiry of W. M. Q., *Coal Age*, Feb. 6, p. 293, regarding a proposed engine-plane haulage combining a 25 per cent. grade 400 ft. long, which was followed by 1000 ft. of a 1½ per cent. grade. In addition to what has already been said in reply to this inquiry, I would like to add a few comments and offer some figures that may be of interest to this correspondent.

In the first place, in order to provide an output of 500 tons of coal per day of 8 hours, as desired, and hauling three-car trips, having a total capacity of $3(5000 - 1500) \div 2000 = 5\frac{1}{4}$ tons, I find that it

would be necessary to haul at a speed of 8 miles per hour, in order to allow 4 min. For making each round trip, with 1 min. to spare for changing ropes, assuming another trip of loads or empties is ready on the arrival of each successive trip on the tipple or in the mine. This is assuming, as was previously estimated, that there will be 500 ÷ 5¼ = 95 trips a day, or say a trip each 5 min.

Allowing such arrangement to be possible, for the sake of argument, the question then resolves itself into whether or not the empty trip will pull the rope back to the bottom, at the estimated speed of 8 miles per hour. Neglecting the weight of the rope, that of the empty trip is 3 × 1500 = 4500 lb. A speed of 8 miles per hour is (8 × 5280) ÷ 3600 = 11.7 ft. per second. Moving at this speed, the empty trip would have a kinetic energy of (4500 × 11.7²) ÷ 2 × 32.16 = 9577 ft.-lb.

Now, in order to simplify the calculation, let me assume that a 1½ per cent. grade is just sufficient to overcome the track resistance, which will permit the entire kinetic energy to be applied in pulling the rope attached to the end of the empty trip. I will further assume that the 400 ft. of rope lying on the incline will gravitate easily under its own weight and still have sufficient reserve force to unwind the rope from the drum.

There will then be an average length of 500 ft. to be pulled a distance of 1000 ft., on the lower grade, by the kinetic energy of the empty trip. The weight of this average length of rope, previously estimated as 0.39 lb. per foot., is 500 × 0.39 = 195 lb.; and, taking the rope friction as 1/40 of its weight, the work performed in pulling the rope 1000 ft., on the 1½ per cent. grade, will be 1000(195 ÷ 40) = 4875 ft.-lb.

Now, taking the assumed data as more or less closely approximating the fact, it appears that it will be possible for the empty trip to gravitate the entire distance of 1000 ft., from the foot of the incline to the side track in the mine, and drag the rope behind it, while maintaining the estimated speed of 8 miles per hour.

However, allow me to suggest that, in order to provide against all contingencies, particularly the necessity of stopping the trip at some point on the lower grade, before it has reached the side track at the end of the haul, it would seem advisable to adopt some type of tail-rope haulage by which the empty trip could be pulled back into the mine, instead of relying wholly on the proposed engine-plane system.

It should be observed, here, that the assumed speed of hauling (8 miles per hour) is greater than what can be safely estimated, under the conditions presented in this inquiry. Also, the time allowed for changing ropes being 1 min. for each round trip, or ½ min. at each end of the haul, is hardly sufficient and provides no margin for delays that may, and invariably do, occur in mining practice.

Moreover, if the cars must be dumped and returned at once into the mine, it will be necessary to provide a rotary dump of three cars' capacity, into which the trip can be hauled without removing the rope. Such an arrangement will permit the three cars to be dumped at once and returned promptly into the mine.

Pittsburgh, Penn. SHELDON SMILLIE.

In connection with the above estimate, it may be well to draw attention to the high speed with which the empty trip would reach the foot of the incline if unrestrained by a brake applied to the drum. Starting from rest at the head of the incline and ignoring the weight of the rope, that of the empty trip being 4500 lb.; and, further, assuming the track resistance as, say, 20 lb. per ton, the velocity attained at the foot of the incline would be

$$v = \sqrt{2gs\left(\sin a - \frac{\cos a}{100}\right)}$$

$$= \sqrt{2 \times 32.16 \times 400\left(0.24249 - \frac{0.97015}{100}\right)}$$

$$= \sqrt{25{,}728(0.23279)} = 77.4 \text{ ft. per sec.}$$

This would mean a speed of (77.4 × 3600) ÷ 5280 = 52.7 miles per hour. The chief difficulty on this first steep grade is, therefore, to hold the descending cars in check by means of a good brake on the drum.

Attention should also be drawn to the manner of computing the result of applying the stored energy of the empty trip (9577 ft.-lb.) to the work of dragging an average length of 500 ft. of ½-in. rope, weighing 500 × 0.39 = 195 lb., a distance of 1000 ft. Assuming the resistance of the rope to be 1/40 of its weight, the work to be performed is 1000(195 ÷ 40) = 4875 ft.-lb.

In performing this work, the velocity of the empty trip is gradually reduced, assuming the initial velocity, as estimated, to be v_1 = 11.7 ft. per second, and calling the velocity with which the trip reaches the side track, 1000 ft. distant, v_2, we have

$$\frac{4500}{2 \times 32.16}(v_1^2 - v_2^2) = 4875$$

$$v_2 = \sqrt{11.7^2 - \frac{64.32 \times 4875}{4500}} = 8.2 \text{ ft. per sec.}$$

However, had the calculations made proper allowance for the effect of the 1½ per cent. downgrade, it would have been found that the empty trip would arrive at the side track with a slightly increased velocity, owing to the effect of the grade, which here exceeds the resistances of the rope and the track combined.

Carbon as a Fertilizer

Letter No. 1—I read with surprise the item in *Coal Age*, Jan. 9, p. 52, drawing attention to a statement made in a previous German publication—the *Zeitschrift fur Angewandte Chemie*—claiming that "carbon is gradually converted into carbon dioxide when added to the soil in a finely divided state," and suggesting that the waste heaps in the neighborhood of collieries could be used, with a possible addition of lime, as a fertilizer to take the place of manure where that is scarce.

Being interested to learn what value, if any, there might be in this suggestion, I wrote to the Pennsylvania State College for their opinion, and beg to submit the reply of Charles W. Stoddart, professor of agricultural chemistry at the college, which is as follows:

Replying to your inquiry regarding the value of coal dust, preferably mixed with lime, as a producer of carbon dioxide for benefiting plant life, permit me to say that, since the earth's atmosphere contains sufficient carbon dioxide for the use of all plants, it would be a waste of material to employ coal dust for that purpose. The mixture of coal dust and lime would be of absolutely no more value than the lime alone. Although this information may be disheartening, it must be accepted as based on facts.

It has occurred to me that the reply of Professor Stoddart, in this connection. will be of considerable

interest to many who read the item to which I have referred. It may, perhaps, at least prevent some useless experimenting on the part of persons who are always anxious to make use of waste products wherever this is practicable. E. S. S.

Shickshinny, Penn.

[*Coal Age* published the item to which reference is here made and gave its authority, believing that that was sufficient. Like everything else that has come from Germany in recent years, this bit of information bears the stamp of camouflage, being interesting if true, but ostensibly untrue and without value. Like the stamp "Made in Germany," German authorship, today, renders all information from that source doubtful. We are glad our correspondent has exploded this bomb hidden in the waste heaps of collieries.—EDITOR.]

Efficiency in Mine Management

Letter No. 3—Admitting the fact that the present coal market is weak, this is a mighty good time to study the question of efficient management of mines, and to winnow from the chaff a great many facts that will be of service to the man who acts upon them within the next few months when the coal business will again come into its own.

Merely *thinking* of efficiency gets us nowhere. There are hundreds of labor-saving devices and expense-reducing equipment now on the market that cannot fail to put dollars into the pockets of every producer of coal, but which are now absorbed in expense items.

In his article on "Expediting Locomotive Haulage," *Coal Age*, Jan. 30, p. 244, Maverette Ashley gives some thoughts that are capable of being transformed into dollars by the man that reads and acts. Speaking of the use of roller-bearing wheels for mine cars, Mr. Ashley presents facts that are conclusive.

Efficiency Shown in Choice of Equipment

A friend recently told me that, seven years ago, he adopted roller-bearing cars hauled by a 13-ton electric locomotive, which has since traveled 40,000 mi. in its service in the mine. He has employed the usual type of motor runner, and states that it has been necessary, in all that time, to purchase but one new set of tires and replace but one armature. He attributes this remarkable performance to the low draft required to start and haul trips of cars equipped with these bearings.

In another instance, a storage-battery locomotive, hauling modern equipped mine cars, brought out of the mine 600 tons of coal, in a single shift. Facts like these prove that efficiency in mine equipment pays. In still another instance, where a large company operated two mines, located on opposite sides of a creek, it was found difficult to hold the men in one of these mines, owing to their preference to work in the other mine. Investigation showed that the only cause for this preference was the fact that the first mine was equipped with cars having plain-bearing wheels, while roller-bearing cars were in use in the other mine across the creek.

There is no use denying the fact that men seek work where it is most easily performed. Operators are face to face with this condition today. But, instead of discouraging this attitude of the men, it should be encouraged, and every effort should be made to lighten manual labor if we desire to increase the efficiency of that labor.

I thoroughly agree with the statement made by "Observer" on page 246 of the issue to which I have previously referred, where he ascribes the success of a certain mining man to the fact that he had learned long ago that "his job is not an office job." I call to mind now three mining men, each in charge of big interests in this state, who never acted on the motto, "Let George do it." Out on the job all day long, inside the mine and everywhere that work was being done, these men were present observing and directing. The results can be well imagined; the dividends were satisfying and there was no need of apologies based on unprecedented prices for equipment, increase of labor rates, shortage of cars, etc., etc.

Speaking of mine-car wheels, I recall, one company who spent $7000 for repairs, in replacing 20 per cent. of their wheels, in a single year. The same company objected to placing modern cars in their mine alongside of the old cars in use. They stated that it would cause dissatisfaction among their men, and they would be obliged to change their entire equipment and throw out the old cars. The argument is but a weak apology for the failure to recognize the great gain in efficiency within their grasp. I have even known operators to refuse to install labor-saving equipment capable of producing known economies, claiming that more intelligent labor would be required for its operation.

Profiting by the Experience of Others

The kind of efficiency that I am urging is the ability to see and act on a suggestion that will produce from 1¼ to 5 tons, for the same money that was formerly required to produce 1 ton. I refer to the kind of management that considers it worth while to reduce the cost a quarter of a cent per ton, when this can be done by improved equipment.

It is such efficiency that led one of the best mining men in this country to build his mine cars a few inches lower than the other fellow's, and yet make them to hold the same weight of coal. He has no trouble in holding his men, who find they can load a car and a half in the same time that is required to load a single car at the other mine.

That superintendent was a practical man; he designed his own cars according to his own particular needs, without attempting to follow any other type. It would be difficult to estimate, in dollars and cents, what such efficiency on the part of a superintendent is worth to the company who employs him.

Too often the efforts of an efficient superintendent to reduce prospective costs, by the purchase of a better type of equipment, are not appreciated or supported by the management, who find too late that it would have saved them heavy losses had they acted on the suggestion. It is gratifying, however, to know that many companies are now beginning to see that it pays to study real efficiency and to act on the many practical suggestions made along this line.

Many companies, however, fail to properly correlate their efforts. Let me ask, of what use is a 3000-ton tipple, unless there are cars and motors capable of handling this output of coal? Of what use is it to build 600 cars when 400 cars of another type will handle

the same output of coal? Why employ two 10-ton locomotives to do the work of two 8-ton machines? Why use 1000 lb of lubricant on mine cars when it is possible to employ cars that will operate as well and better with 300 lb. of lubricant? It is important to *correlate* our ideas of efficiency. ECONOMIST.

Hunting, W. Va.

Efficiency of Mine Officials

Letter No. 4—In the discussion of efficiency, much will depend on the accepted meaning of the term. For example, from the operator's standpoint, the efficiency of an official is determined by his ability to produce a large tonnage at a low cost of operation, without regard to the actual conditions.

According as conditions are favorable or unfavorable to production, one official will produce results that mark him as "highly efficient," in the estimation of his employer. On the other hand, another man may do far more creditable work and yet be unable to make the same showing, in a low cost per ton of coal produced. As a result, in the estimation of the management, the latter is "less efficient" than the former. But, the real underlying causes were the favorable conditions that assisted the one official and the unfavorable circumstances that retarded the other.

Development Under Favorable Conditions Is No Proof of Efficiency

By way of illustration, let me assume that a company is about to open a mine in a 6-ft. seam of coal, which is overlaid with a good sandrock roof at the start. We will suppose that the preliminary work has been done and the mine put on an operating basis. The company is willing to furnish anything that is necessary to push the development to the point where a good output will be secured.

With this purpose in view, the headings are double-shifted and rooms are opened, in good coal, as quickly as there is space for them to be turned on the entries. The height of the seam is such that there is no necessity to brush the roof or lift bottom, in order to provide the required headroom on the haulage roads. Also, all the rooms are standing in good thick coal. Finally, with proper management, there will be little trouble from roof falls and the cost of timbering in both rooms and headings is low.

Under these favorable conditions, the work of development proceeds rapidly, and the mine becomes a large producer, while the costs of operation are comparatively low. The management give little thought to the future prospects of the mine, or dream that these favorable conditions can hardly be expected to continue always. But, in the meantime, the length of haul is extending and it becomes necessary to make provision for the installation of suitable haulage facilities, drainage systems, and other equipment that will provide adequate ventilation in every section of the mine.

About this time, moreover, there are indications, at the faces of some of the headings, that predict changes in the roof conditions. In one section of the mine, the sandrock has given place to a weak shale containing slips and faults. In another section the headings, which have been gradually dipping, take a sudden rise and the coal is getting thinner. Evidently, the palmy days of the past two or three years are giving place to the time when the management must devise the easiest methods for overcoming the growing difficulties.

Now is the time for the mine superintendent to prove whether or not he has any real efficiency. His fitness will be shown by his ability to adopt more adequate means of drainage and ventilation and improve the system of haulage in a manner that will overcome the increased cost of hauling from greater distances than before. Siphons and pump lines must be arranged to afford good drainage of the roads, which must be maintained in the best possible condition. The ventilating system must be arranged to shorten the distance of air travel, and the air current must be split so as to produce the largest air volume with the least power.

Ability to Master a Situation the True Test

Failure to meet such a situation as the one here described and which must develop sooner or later in every mine, will prove the inefficiency of a superintendent whom the management had been prone to regard as "highly efficient" while things were coming his way. As previously remarked, herein lies the test of true efficiency—the ability to contend successfully with untoward circumstances and conditions.

But, let me suppose that this same mine changes hands, just at the time when it has reached its point of decline. The new officials take hold at a most inopportune moment in the life of the mine. There is much work to be done in cleaning up and starting headings that had been stopped in low coal. Ripping will be required in driving these headings and they must be timbered and graded, all of which increases the cost of operation, while the output becomes less and less owing to the thinning out of the seam.

The proposition here presented is a difficult one. The company must practically open up a new mine, besides cleaning up the old one. Yet *efficiency* on the part of the man in charge will tell. Many supplies in the way of rails and timber will be recovered from abandoned workings; and, finally, the mine will be put on a fair working basis, notwithstanding the increased length of haul and the difficulties of ventilation and drainage. This work of recovering a mine is practical work and requires the highest kind of efficiency on the part of the man in charge.

Again, there are instances on record where changes have been made in the management of mines just as the mine was on the very verge of producing better results than formerly, and the palmy days of large tonnage and low costs were yet to come. The new management then receives the credit for greater efficiency than is their due. Instead, the real credit for putting the mine on its present basis belongs rightfully to the party first in charge.

The point I wish to emphasize, here, is that efficiency must be studied in the light of the practicability of the work in charge. Results are largely determined by coöperation on the part of mine officials, who should be governed by the same purpose of making the mine pay. There should be no quarrels. It is unnecessary for the superintendent to tell the foreman that he is the boss, which the foreman already knows. Coöperation should be the watchword if we expect to succeed.

Rossiter, Penn. J. T. JONES.

INQUIRIES OF GENERAL INTEREST

Comparative Costs in Salt Mining

Kindly permit me to submit the following problem, regarding the comparative cost of two proposed methods, in the mining of salt. One proposition is to pump the salt to the surface in a saturated solution, using for that purpose a centrifugal pump discharging through a 6-in. wood or cast-iron column pipe, the lift being 60 ft. from the sump to the surface. The second proposition is to hoist the rock salt in solid form, using, for that purpose, a self-dumping bucket.

What is desired is to ascertain the comparative cost of handling 60 tons (2000 lb.) per hr., by these two methods. Alternating current of 220 or 440 volts is to be used for driving the motor. When pumping the brine, as in the first proposition, the concentrated solution is to be discharged through a vertical column pipe to a height of 60 ft. In the second proposition, when hoisting the solid salt in buckets, there is first a vertical lift of 15 ft., which is followed by a 20-deg. incline 150 ft. in length. A ¾-in. cable is used in this hoist. The bucket, which is self-dumping, weighs 500 lb. empty and 1500 lb. when loaded to its capacity with salt.

We submit this proposition to *Coal Age* and its readers, hoping for their advice and suggestions, which will be greatly appreciated.

Oakland, Calif. ENGINEER.

So much depends on conditions when considering two propositions of this nature, that *Coal Age* is able to give but a suggestive outline of the relative cost, assuming average efficiencies and other data that can only be taken as approximating more or less closely the actual facts.

1. In the first proposition, rock salt will require about 2½ times its weight of water to form a concentrated solution of brine. The handling of 60 short tons, per hr., of solid salt in a concentrated solution, will require the pumping of 7000 lb. of brine to a height of 60 ft., each minute. In estimating the power we will assume an over-all efficiency in the pump and the motor of, say 60 per cent., and ignore both the velocity head and the friction head, which are inappreciable when discharging 700 gal. through a 6-in. pipe 60 ft. long. The power required, in this case, is

$$H = \frac{60(7000 \times 60)0.746}{0.60 \times 33{,}000} = 950 \text{ kw.-hr.}$$

2. In the second proposition, the bucket holds 1000 lb. (½ ton) and, to handle an output of 60 tons per hr., will require two full hoists or round trips each minute, hoisting practically 1500 lb. to a total vertical height of $15 + 150 \sin 20° = 15 + 150 \times 0.2588 =$ say 69 ft. Here, so much depends on the mechanical arrangement and equipment, that it is only possible to guess at the efficiency of the hoist, which we will assume as 50 per cent. Making two hoists per minute, or 120 hoists per hour, and assuming an efficiency of 50 per cent., the power required will be, approximately,

$$H = \frac{120(1500 \times 69)0.746}{0.50 \times 33{,}000} = \text{say } 560 \text{ kw.-hr.}$$

It is difficult, however, to see what arrangement can be adopted, in the second proposition, to permit of making a round trip in 30 sec., including the time of dumping and changing buckets below.

Exhaust from Steam Pump

Recently, I have had quite an argument with our pumpman, in regard to the proper method of connecting up the exhaust of a steam Cameron pump, so as to avoid the annoyance caused by the exhaust steam.

Our pump is located at the foot of the slope and the exhaust steam often makes the place so hot that it is difficult for the men to work there. We have decided that something must be done to improve the condition. Either we would have to turn the exhaust into a barrel, or make connection direct with the pipe line.

In talking over the matter, I claimed that this connection should be made with the suction pipe. The pumpman, however, claimed that the exhaust should be conducted into the column pipe through which the pump was discharging, making the connection at a certain distance from the pump. The pump is operating under a boiler pressure of 120 lb. gage.

Kindly state which method is correct—whether the exhaust should be connected with the suction or with the column pipe, and why.

———, Mo. ASSISTANT SUPERINTENDENT.

The exhaust from a steam pump located in a mine can be, and often is, connected with the suction pipe, using the precaution to enter the exhaust at a point sufficiently below the pump to insure the steam being injected into the water. In a short suction lift, this connection should preferably be made close to the top of the pipe. It is only where the suction lift approaches the theoretical limit, as determined by the atmospheric pressure acting to lift the water from the supply basin to the pump, that it is necessary to use the precaution just mentioned, in order to make sure of the direct contact of the entering steam with the water in the pipe. Should there be any tendency to spasmodic suction, the entrance of the steam at the top of a long suction lift would possibly cause a back pressure, or give rise to water-hammer due to the sudden condensation of the accumulated steam. This condensation should always take place uniformly, as quickly as the steam enters the pipe if the trouble is to be wholly avoided.

Should the exhaust connection be made with the column pipe, not only would the pump be compelled to exhaust under the head due to the water in the column pipe, but the condensation of the steam in that pipe would have a tendency to interfere with the uniform discharge or flow of water from the pump to the surface and disrupt, to that extent, the action of the pump, with the result that water-hammer would often occur, which would be both annoying and harmful.

We shall be glad to have the suggestions and comments of our practical readers regarding this point.

EXAMINATION QUESTIONS

Mine Examiners' Examination, Springfield, Ill., Dec. 17, 1918

(*Selected Questions*)

Ques.—What are the duties of a mine examiner?

Ans.—The primary duties of a mine examiner, as his title indicates, are to examine the mine for any possible danger that may exist on the roads, travelingways, or air-courses, or in the working places. The examination must include all void and abandoned places and falls where gas or other dangers may exist.

The first examination is made in the early morning, within two or three hours of the time set for the men to enter the mine for work. At that time, the examiner must visit each working place and travel the air-courses and roads, following the air current throughout his section of the mine and stopping to make the necessary tests for gas and to examine the roof and timbers to ascertain if there is any danger present. When this examination is finished, the examiner must return to the mine entrance and enter, in a book kept for that purpose, a full report of his work, stating any dangers that he may have found, by describing their nature and location. It is his duty to withhold the checks of any miners whose places he has found unsafe for work and to deliver these checks to the foreman.

The second examination of the mine is made more in detail, and when the men are at work in their places. At that time, it is the duty of the examiner to observe more carefully the condition of each working place and to give any needed instructions to the miners to insure their safety. The coal-mining laws of Illinois require the mine examiner to see that the air current is traveling in its proper course and quantity, and to measure the air passing in the last crosscut, in each pair of entries, or in the last room, in longwall mines, and at any other necessary points and to note the results in a book kept for the purpose. He must mark the date of his examination on the wall of each place examined.

Ques.—What is a regulator and when can it be used to advantage?

Ans.—A regulator is a device for properly proportioning the quantity of air between two splits, according to their requirements. This is accomplished by obstructing the flow of air in that split taking more than its proper proportion. A mine regulator consists of any device that will reduce the area of passage in an airway and, by that means, regulate the quantity of air circulated in that split.

Regulators are used to advantage where the requirements in any section of the mine or in any air split are such as to demand more air than such section or split would receive in the natural division of the air current. For example, in natural division, the larger portion of the air will pass out through the shorter split, while it is the longer airway that will generally require a greater proportion of the air. In such cases, a regulator placed in the shorter airway will obstruct the flow in that split and cause a larger quantity to pass through the longer split.

Ques.—In a certain coal mine in this state, there are 576 men employed, who are using 22 mules to haul the coal. (a) What quantity of air must be entering the mine to comply with the state mining laws? (b) How many splits will be required?

Ans.—(a) If the mine is not generating gas, the quantity of air required by law is 150 cu.ft. per man per min., and 500 cu.ft. for each mule per min., which makes the quantity required, in that case, $576 \times 100 + 22 \times 500 = 68{,}600$ cu.ft. per min. On the other hand, if the mine is generating gas, the law requires that there shall not be less than 150,000 cu.ft. per man per min., which would make the total required circulation not less than 97,400 cu.ft. per min. In any case, the law authorizes the mine inspector to order that these quantities be increased, if he thinks that more air is required, which order must be made in writing.

(b) The law further provides that the main air current shall be so divided as to give a separate split of pure air to each 100 men employed in the mine. This would require, in the present case, six splits of air, unless the mine inspector exercised his power to require a greater number, which he is authorized to do by law if, in his judgment, this is necessary.

Ques.—(a) Where would you expect to find blackdamp and firedamp in a mine? (b) How could you detect the same?

Ans.—(a) In either case, the mixture will be more apt to be found in places where it is generated, provided the mine is properly ventilated, and the quantity of air passing is sufficient to carry away the gases produced and prevent their accumulation in quantity. On the other hand, where the gas generated in a mine is not promptly swept away with the air current but has an opportunity to accumulate, the heavier blackdamp may be expected to be found at the face of dip headings or rooms and in other low places where the circulation is not sufficient to sweep them away. The lighter firedamp mixtures, under similar conditions, may be expected to be found in cavities of the roof or at the face of pitch headings and in rise workings where the circulation of air is insufficient to keep such places free from the gas.

(b) A blackdamp mixture is easily detected by observing its effect on a lamp flame, which is dimmed or completely extinguished by the gas. A firedamp mixture is detected by observing its effect on the flame of a safety lamp, which must be raised cautiously toward the roof. The presence of firedamp causes a small nonluminous cap to form above the flame when small quantities of the gas are present. As the quantity of gas is increased, the height and volume of the flame is increased, and the flame becomes more or less agitated and, frequently, slight explosions will occur within the lamp chimney as the firedamp mixture approaches its maximum explosive point.

Book Reviews

Truth About the Cost of Living

WARTIME CHANGES IN THE COST OF LIVING. Research Report No. 9, National Industrial Conference Board. Pages viii + 81; 6 x 9 in.; no illustrations. National Industrial Conference Board, 15 Beacon St., Boston, Mass.

This impartial and accurate account of the effect of the war on the cost of living may be commended to all parties, whether viewing matters from the standpoint of labor or from the standpoint of capital. It is not based on wholesale but on retail prices. As the report says, the advance in wholesale prices is not reflected in retail prices until months later. It quotes the United States Bureau of Statistics, which in 1901 found that expenditure for food was about 43 per cent. of the total income; for shelter about 18 per cent.; for clothing nearly 13 per cent.; for fuel and light nearly 6 per cent.; and for sundries a little over 20 per cent.

The report sums up food costs as follows: "Although it is true that standards of living, transportation, accessibility to supply and other factors cause some local variations, 60 per cent. to 65 per cent. fairly reflects the advance in food prices from the outbreak of the war in the summer of 1914 to the middle of June, 1918." The figure 62 is taken by the Conference Board to represent a fair average percentage for the increase in costs in food from the outbreak of the war till June, 1918.

Rents have gone up and down. The report, however, says, "On the whole it appears that an estimate of 15 per cent. for the increase in the rent of workingmen's houses is sufficient, except for communities subject to peculiar conditions."

The cost of clothing has soared higher than either rents or food. "It appears," says this monograph, "that a fair estimate of the increase in the cost of clothing for a wage-earner's family between July, 1914, and June, 1918, would be 70 to 80 per cent. As the increase for lower-cost budgets tends to approach 80 per cent. rather than 70 per cent., the average increase has been placed at 77 per cent."

In summing up the cost of fuel and light the report says: "The cost of fuel and light in different cities varied so greatly in response to a number of local conditions, and the price changes have been so divergent, as to make even an approximation of the increase very difficult. It would appear, however, that in June, 1918, the average price of anthracite was 30 to 35 per cent. higher than in 1914; the advance in bituminous coal was considerably greater. The price of gas showed a much smaller percentage of increase and in many cities remains unchanged.

"The increase in the cost of fuel and light has been placed at 45 per cent. This estimate has not the same validity as have those for food and clothing. For the latter the data secured were not only more extensive but more uniform than was the case with fuel and light, for which local conditions determine many of the factors entering into the increased cost. Since, however, fuel and light constitute less than 6 per cent. of the total family expenditure, a considerable variation in the percentage of increase has but little effect on the budget as a whole."

The concluding remarks of the Board are as follows: "Taking into consideration all of the factors in the problem, the evidence points strongly to the conclusion that for the great majority of American communities the average increase in the cost of living between July, 1914, and June, 1918, lies between 50 and 55 per cent. Clothing showed the most marked advance of any of the major items in the budget—77 per cent.—but quantitatively this is less important than the 62 per cent. increase in the cost of food, since food represents about 43 per cent. of the average expenditure, while clothing represents only 13 per cent.

"It should be repeated that in certain localities, particularly where there have been unusual advances in rent, the increase in the budget has been as a whole somewhat greater. Since rent requires about 18 per cent. of the ordinary family expenditure, each further increase of 5 per cent. in this item means the addition of about 1 per cent. to the budget. It is thus a simple matter to adjust the board's estimate to fit communities where unusually large rent increases have occurred. Similar adjustments to allow for local conditions affecting the cost of fuel would not result in an important modification of the general average."

The estimate for the advance in sundries, which sundries make 20 per cent. of the wage-earner's budget, include the advance in carfare, furniture, insurance, medical service, books, recreation, religious and charitable expenditures, luxuries and incidents. The report assumes (really it would appear without believing it to be true, to judge by its comments on each item in turn) that an average of 50 per cent. will represent the increase in cost of sundries. This "sundry" estimate is the lame leg of the whole report. The argument for 50 per cent. could, however, have some show of justification if the item "furniture" were given a place in the elaboration of the argument—for furniture has certainly soared.

Moreover, a further justification would have been found if the board had said, as is in fact true, that insurance has gone up as much as the workingman's budget. Instead the board says lamely, "Insurance has shown practically no change." It is true that $10 will buy as much life or accident insurance as before the war, but when the money is delivered what will it buy?—not so much as before the war but only 66⅔ per cent., assuming that prices have gone up 50 per cent. A workingman is no longer as well insured as he was before the war unless he has increased his insurance premium.

It is the same with savings. Savings, like insurance, represent deferred purchases. If the cost of the things to be furnished, the food, shelter, clothing, fuel and light rise in price, the savings and insurance should be higher to meet them. British figures of increased cost of living as quoted recently by the United States Bureau of Labor Statistics are similarly vitiated.

However, the report is unbiased and in every way excellent. It is an authoritative statement, capable of amendment for certain local conditions, and it will show which wage increases had a degree of profiteering taint and which wage increases were too small. It will show who were profiteers and who the sad victims of wage profiteering. All who received increases in wage above the increase in cost of living and cost of transferring their labor were profiteers. All who received advances in wage less than the advances in cost of living were victims of the profiteering on the part of other laboring men.

More Short Monographs Wanted

MINE TRACKS, THEIR LOCATION AND CONSTRUCTION. By J. McCrystle. Pages x + 102 + 3 index, 23 ill. McGraw-Hill Book Co., Inc., 239 West 39th St., New York City. Leather. Price, $1.50 net.

An extremely welcome reprint of articles appearing in *Coal Age* is J. McCrystle's "Mine Tracks," treating briefly and well of the materials used and the principles involved in the design and installation of mine tracks and containing rules for standard practice. We need a series of inexpensive monographs of this sort on all the many phases in coal mining, and we trust that one so capable as Mr. McCrystle may soon venture to meet in one or more directions the public's urgent need.

FOREIGN MARKETS AND EXPORT NEWS

Output and Distribution of British Coal in 1918

The following table, which has been prepared by the Department of Coal Supplies of Great Britain, shows the output and distribution for 1918, as compared with 1917 and the pre-war year 1913. The reduction of 16½ million tons—about 10 per cent. in home consumption in 1918, as compared with 1913—in spite of the increased requirements of industries and transport connected with the production of munitions, was brought about by the curtailment of supplies to less essential industries and for domestic consumption. Exports were at the same time restricted to the quantities necessary to supply the requirements of the Allies, and to meet obligations to neutrals in connection with agreements, under which they furnished England with shipping and other services essential to the successful conduct of the war.

	1913	1917	1918
	— Millions of Tons —		
Output	287½	248	226½
Withdrawal from stocks at pits	....	....	1½
Additions to stocks at pits	....	2	....
Mine consumption and miners' coal	22½	22½	22½
Net output distributed	265	224½	205½
Bunkers (foreign and coastwise) and Admiralty shipments	25½	27	25½
Exports	77½	38½	34½
Home consumption	162	159	145½
Totals	265	224½	205½

Foreign Freight Rates

W. W. Battie & Co.'s coal trade freight report for Mar. 10 states that freight market conditions are practically the same as a week ago, and the few charters completed for export coal during this period were at the Chartering Committee's maximum rates. There is little demand for steamers to take coal to West Indian ports, but the demand continues for tonnage for South American ports. Tonnage is difficult to obtain to latter destinations. The Chartering Committee's rates are as follows:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis., Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge.

Sail (maximum) — Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net; Santos, $19.50 net; Buenos Aires, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. (Gross rates $1.50 per ton in excess of net rates). On all the foregoing rates, charterers pay vessel's towage to coal port. To Nitrate Range, $16.50 gross prepaid. (Same rate steam.)

The Chartering Committee's rate by steam is $19.50 net, with 1000 tons dis. to Rio, $19.50 net, 1000 tons dis., or $21, 600 tons dis. to Santos; $18.50 net, 1000 tons dis. to Buenos Aires, and $19.50 net, with 750 tons dis. to Montevideo.

Danish Coal Imports in 1918

In November, 1918, Denmark imported 72,086 tons of coal from the United Kingdom; 19,254 tons from Germany; 156 tons from other places. In October, 1918, the coal exports to Denmark from the sources enumerated above totalled 61,167 tons, 42,512 tons and 156 tons respectively. For the period January to October, inclusive, 1918, the Danish coal imports amounted to 889,742 tons from the United Kingdom, 620,792 tons from Germany and 2227 tons from other places.

During December, 1918, the importation of coal virtually ceased, due to the disturbed conditions in Germany and the fact that England temporarily stopped coal shipments to Denmark following the armistice.

The "Calcutta Gazette" reports that only 1,014,993 tons of coal were exported from Calcutta in 1918, as against 3,017,180 tons in 1913-14.

To Construct Barge Fleets for Shipping Coal South

The Mississippi Valley Association, which represents commercial and shipping interests, is planning extensive development of the inland waterways, especially the Mississippi River and its tributaries, as a means of promoting the expansion of foreign trade, particularly in coal. The plan contemplates the construction of barge fleets for the transportation of coal to the South American markets. It is believed that coal cargoes originating on the Ohio, Monongahela, Kanawha and Warrior Rivers and the tributaries of the Mississippi, can be shipped to New Orleans and thence to foreign ports at a lower rate than is now given in all-rail routes to the seaboard and from Atlantic ports to the South American countries.

Coal and Coke Exports from New York in January

Comparison of the coal and coke exports from the Port of New York during the month of January this year shows a decided gain both in tonnage and valuation as compared with January of 1917 and 1918. The table also shows that the markets for anthracite and bituminous coals have changed considerably, while the markets for coke remain, with a few exceptions, practically the same. The tabulations follow:

To	Anthracite						Bituminous						Coke

COAL AND COKE NEWS

What Happened in February

[The bracketed figures in the text refer to pages in the present volume and should the reader desire further information he can obtain it by reference to the pages indicated.]

Feb. 1—Mine Workers' representatives meet presidents and secretaries of New River Association and Winding Gulf Operators' Association at Charleston, W. Va., who refuse to discuss a new scale regarding demand as in violation of contract [XV, 370]—Maximum prices on anthracite and all the coal and coke regulations, except three, are suspended [XV, 282]—Allison O. Smith, special umpire of Fuel Administration, makes several decisions for New River and Winding Gulf fields [XV, 411].

Feb. 3—Florence and Sydney mines of Nova Scotia Steel and Coal Co. closed down owing to alleged interference of Dominion Iron and Steel Co. with its workings [XV, 339. 456].

Feb. 5—Annual banquet of Engineers' Society of Northeastern Pennsylvania [XV, 364].

Feb. 7—White mines of H. C. Frick Coke Co. are abandoned [XV, 382]—River tipple and trestle of Hecla Coal and Coke Co., Isabella, Fayette County, Pennsylvania, destroyed by fire [XV, 382].

Feb. 10—Store of Federal Coal Co. at Cary, Ky., burned down [XV, 382].

Feb. 11—Alicia mine of W. H. Brown, with 400 coke ovens, all located just above Brownsville, closed down indefinitely [XV, 382]—Coal price regulation in Canada ends [XV, 422].

Feb. 14—Southern Appalachian Coal Operators' Association meets at Louisville, Ky. [XV, 397, 398]—Mine workers of West Virginia parade at Charleston, W. Va., as a protest against "Red flag bill" [XV, 457].

Feb. 17—American Institute of Mining Engineers meets at New York City, adjourning Feb. 20 and changing its name to American Institute of Mining and Metallurgical Engineers [XV, 237, 448, 449].

Feb. 18—J. R. Gilmore, president District 29, and Lawrence Dwyer, international board member of same district, arrested as implicated in shooting affray [XV, 498].

Feb. 20—Mr. Deitrich, representative from Allegheny County, Pennsylvania, introduces bill providing that where injury arises from failure of employer to obey safety requirements no consideration shall be allowed to affect liability of em ployer [XV, 498].

Feb. 21—Frank Farrington advocates 6-hour day, 5-day week, as cure for shortage of demand for coal [XV. 499]—Fire breaks out in the South Wilkes-Barre No. 5 colliery of Lehigh and Wilkes-Barre Coal Co., and is walled in on Feb. 23 [XV, 469].

Feb. 23—Sir Guy Spencer Calthrop, controller of British Coal mines, since 1917, dies of influenza [XV, 471].

Feb. 24—The Amalgamated Mine Workers of Nova Scotia sign contract providing for 8-hour day with no suspension for meal [XV, 499].

Feb. 25—V. Everit Macy announces that the National War Labor Board awards the marine workers of New York an 8-hour day, 6-day week and a week's holiday a year, the short day to be paid for at the same rate as the long day. No retroactive provisions or increase in wage incorporated in decision.

Feb. 27—Meeting of New York State Coal Merchants' Association—Wood tipple at Kellar-Klondyke mine near Clinton, Ill., is blown down by explosion [XV, 510].

Feb. 28—William C. Redfield announces formation of Industrial Board of Department of Commerce to stabilize prices at a lower and "equitable" level.

Harrisburg, Penn.

On Mar. 13 Governor Sproul addressed a letter to Attorney General Schaffer asking what powers are vested in the State government to inquire as to the cause for the proposed advance in the price of anthracite, after a mild winter and when mines are on short time because of a lessening of demand, and suggesting that, if necessary to secure authority, the matter be referred to the Legislature, which is now in session. The Governor's letter follows in part:

I know there have been investigations of one kind or another by committees and commissions from different authorities and that the first result of the recent intervention of the Federal Government in the matter was an immediate and wholesale increase in prices, especially to the small consumer. Our Legislature now being in session, it has occurred to me that, if we lack the legal machinery to make the proper inquiries and to protect our people against any unreasonable profiteering in this necessity of life here in Pennsylvania, now is the time to establish such machinery. If we have the power to regulate the prices of food and other essentials of life for our people, have we not some rights in the question of fuel prices in case we should be able to establish the fact that hard coal costs are unreasonably high?

Coming right at this time, when the efforts of patriotic people everywhere are directed toward restoring the cost of living to a normal basis and when we are all bending every energy to provide means of employment in order to help stabilize labor conditions in the country, it would seem to me that there would have to be extraordinarily good reasons to justify an increase in the cost to our people of such a necessity to comfortable existence as anthracite coal.

If it is necessary to have a legislative commission investigate the matter, or action is required in other lines to make the power of the State effective in the situation, I am prepared to recommend such action upon the receipt of your advice as to how best to accomplish the results we desire. I shall, therefore, be greatly obliged to you if you will give immediate consideration to this communication.

Uniontown, Penn.

The Pittsburgh Steel Co. is now the owner of the Alicia No. 1 and No. 2 mines, 2400 acres of Fayette and Greene County coal, the marine ways adjoining the mines on the Monongahela River and a fleet of three river tugs and 50 barges. The property was sold by Capt. W. Harry Brown, one of the largest independent coke operators in the Connellsville region, for a consideration of approximately $4,000,000. The deal has been pending for several weeks and several times has been reported consumated. Confirmation of its closing in Pittsburgh last Saturday morning was made a few hours later at the Brownsville office of the Brown interests.

The deal represents one of the largest transfers of coal property in recent years and removes from the market one of the best brands of coke manufactured in the Connellsville region. The entire output of the two plants will be used to supply fuel for the mills of the Pittsburgh Steel Co. Heretofore the steel concern has been securing the major part of its coke supply from the W. J. Rainey interests.

Involved in the deal is the Alicia No. 1 works at Brownsville and the Alicia No. 2 works at Grays Landing, on the Greene County side of the Monongahela River. The output of the two Alicia plants will be hauled in barges down the Monongahela River to the Monessen mills of the Pittsburgh Steel Co. about 15 miles distant.

The Alicia No. 1 plant is reputed to be one of the most modern and best equipped coking plants in the Connellsville region. Construction of that plant was commenced in 1908. The plant includes 400 rectangular ovens equipped with the Mitchell McCleary doors. The pusher, leveler and conveyor installed is the product of the Connellsville Machine Car Co. There are 500-hp. Buckeye engines and the power plant has a capacity of 600 kw. One of the features of that plant is a large steel traveling bridge which spans a double railroad track and joins a river tipple. A coke crusher is located at the upper part of the plant and has a capacity of 15 to 18 cars of crushed coke daily. The traveling steel bridge represents an investment of $200,000. At the works are 150 dwellings for workmen as well as the administration building which contains the company store, post office and offices.

Coal land involved in the sale was purchased in 1912 from J. V. Thompson. There were originally 1000 acres at the Alicia No. 2 plant, but Mr. Brown later acquired 800 acres. There yet remain 1000 acres undeveloped in the Alicia No. 1 field. Shipments from Alicia No. 2 are entirely by river, but facilities both for rail and river shipment are maintained at Alicia No. 1.

Charleston, W. Va.

It was rather startling to learn that a car shortage was developing during the week ending Mar. 15 in all districts through which the Chesapeake & Ohio Ry. passed. This has been expected for some time, because it was realized that when orders for coal did become more plentiful it would be found that many cars were tied up with unloaded coal or else scattered to the four winds, as is now the case. Of course, this means in West Virginia that there is an augmented demand for coal and that mines are beginning to be operated on a more regular schedule.

So far, however, there has been no material increase in the output, production during the first and second weeks of March averaging about the same as it had during the latter part of February. It was significant, also, that there had been no further decreases and that if anything there had been a further advance, although the trade had not had an opportunity to fully respond to an improvement in market conditions.

What caused operators to look for an increase in orders was the significant improvement in the New England market and the fact that an accumulation of coal at tidewater points had been greatly reduced. However, there seemed no prospect of any large volume of export business. West Virginia producers also observed a more insistent call for coal in the Western market.

Surplus stocks of coal are being so rapidly depleted that West Virginia coal men feel assured that just as soon as lake navigation is resumed, in a few weeks, it will be a signal for the resumption of general activity in the mining business. The prediction is even made that by July there will be such a stiff demand that there will be an increase of at least a dollar per ton on coal. During the first part of the week beginning Mar. 10 mines were being operated on about a 50 per cent. schedule, as against about 40 per cent. for the previous week. That meant some mines at least were running three days a week as against one and two days during previous weeks.

Dallas, Tex.

Texas lignite beds will soon be developed and the lignite produced therefrom used as fuel by the industries of this state, thus eliminating the necessity of shipping coal for fuel from long distances to industries situated on extensive lignite beds in east and northeast Texas. The Federal Government's Bureau of Mines is preparing to locate an experimental plant in Texas in close proximity to the lignite producing areas in an effort to work out some plan by which the Texas lignite may be dehydrated and rendered more fit for fuel.

The difficulty with the Texas product has been that it has such a high water content that its use as fuel has been thereby rendered impractical, and industries situated over extensive lignite beds have been forced to ship coal from Oklahoma or Colorado for use in their furnaces. Experts of the Federal Bureau of Mines believe that by a carbonizing process the lignite may be made fit for fuel. This process, it is explained, is similar to coking and leaves as a residue a gas which also has value

for its commercial use. The coal or lignite remaining can be burned in an open grate, in furnaces, or made into briquets approximating anthracite coal.

The location of this experimental plant has been taken up by the Texas Lignite Operators' Association, and at a meeting last week at Waco the situation was discussed. It is considered likely that Waco will get the plant, as the Government has announced that the location will be largely determined by nearness to lignite beds and to a city at which the gas produced from the plant could be marketed, and Waco offers both of these. Lignite can readily be delivered from the beds in Milan County, some of the most extensive in the state, to Waco for $2 a ton, the cost at the mine being $1.50 a ton, and Waco at this time is planning the erection of a municipal artificial gas plant. The by-products from a ton of lignite, it is estimated by the lignite operators, would be worth $22.

New York, N. Y.

A committee composed of J. R. Thomas, president, Carbon Fuel Co., Charleston, W. Va.; W. G. Ireland, sales manager, Jamison Coal and Coke Co., Pittsburgh, Penn.; Harry Boulton, president, Central Pennsylvania Coal Producers' Association, Clearfield, Penn.; John J. Tierney, vice president and general sales manager, Crozier-Pocahontas Coal Co., Philadelphia; John J. Brophy, treasurer and general manager, Piedmont and Georges Creek Coal Co., Frostburg, Md.; Arnold Gertsell, sales manager, Percy Heilner and Sons Co., Philadelphia, and Wilbur A. Marshall, president, Wholesale Coal Trade Association of New York, was appointed to revise the rules of the Tidewater Coal Exchange, and particularly the classification of mines, at a meeting held in Washington, D. C., on Mar. 14 and 15. The meeting, which was held at the Shoreham Hotel, was called by the Executive Committee and Permanent Railway Committee of the Tidewater Coal Exchange to consider objections which had been made or were to be made to the rules, regulations and practices of the Exchange. It was attended by about 150 operators, trans-shippers and consumers.

After the various complaints had been discussed, and new recommendations had been considered, Charles S. Allen, secretary of the Wholesale Coal Trade Association of New York, offered a resolution providing for the appointment of a committee to revise the rules of the Exchange, and also the classification of mines.

During the meeting F. M. Whitaker, of the U. S. Railroad Administration, read a statement which showed the saving to the railroads, from Aug. 1, 1917, to Jan. 31, 1919, to have been:

Tonnage dumped	48,785,967
Number of cars dumped	967,800
Car days saved on gross detention basis	1,747,600
Saving effected on per diem	1,048,560
Cars saved	47,035
Investment necessary to have procured 47,035 cars at $2900 per car	$136,401,500
Interest on above investment at 6 per cent	$8,184,090
Credits extended to members (excluding Government members), tons	3,000,000

As a result of the meeting it is more than likely that the Exchange will be continued in operation, it being favored by the Railroad Administration and a large proportion of the coal operators and shippers. The committee is to meet in Philadelphia, Friday, Mar. 21, at the offices of the Tidewater Coal Exchange.

Victoria, B. C.

There has been a revival in Vancouver, B. C., of the agitation against the coal dealers because of what is termed the excessive cost of fuel to the consumers in view of the fact that the coal mines of Vancouver Island, the sources of supply, are only some sixty odd miles distant. The discussion arose through the statement of T. D. Bulger, Dominion Fair Wage Officer, that the Island miners obtained their domestic coal for $4.50 a ton, with an extra dollar a ton for delivery. This was the same coal which was selling in Vancouver for $10.15 a ton. The dealers declare that their profit at the latter selling price is not more than from 40 to 47c. a ton. They say that they buy their coal at $6.45 or $7.20 a ton loaded on the scow at Vancouver Island, but that added to that figure are such expenses as freight charges, insurance, unloading, screening, sacking and delivery. These items, with the wages of all engaged in the operations at from $4 to $5 a day and a loss in screening of from 10 to 15 per cent., accounted for the difference between the purchase price at tidewater on the Island and in the cellars of the consumers.

If the coal miners were getting their coal for $4.50 at the pit mouth the opinion was expressed by the dealers that they must be obtaining it below cost. It was further explained that the reason that some dealers were able to sell at $10.15 and others were forced to charge $10.50 a ton was that the Fuel Controller had issued an order requiring the Canadian Western Fuel Co. to sell at not more than $6.45 per long ton loaded on scows, while the Canadian Collieries (D), Ltd., were permitted to dispose of its coal at a higher figure, which it had fixed at $7.20 per long ton on scows. This decision had been reached after an investigation into the cost of production in the cases of the different collieries of the Island. The dealers' contention is that the prices to the consumers are based on expenses and a profit to them of not more than from 40 to 47c. a ton.

PENNSYLVANIA

Anthracite

Hazleton—The G. B. Markle Co. has announced that the war gardens which were a great success for the past two years will be continued this summer. The plots, 30 x 100 ft., are rented for $1 a year, which includes plowing and fertilizers.

Hazleton—Plans considered by the Lehigh Valley Coal Co. to electrify a number of additional operations of that company have been given a setback, because of the high price of materials and labor, it was learned on Mar. 10. Especially was work planned for the Lehigh region, and this has been halted by the holding up of prices for materials. This condition makes future plans of the company rather uncertain.

Shickshinny—A recent fire which destroyed bridges spanning the Susquehanna River has made it necessary for the West End Coal Co., across the river from Shickshinny, to place a number of large boats in service so that the mine employees living on the opposite side of the river from the mines can get to work in the morning. Over 500 men a day are taken over in small rowboats. The county and the coal company are arranging to place several ferry boats in use as soon as they can secure them.

Hazleton—H. M. Crankshaw, former manager of the Cranberry Creek Coal Co., has been retained as consulting engineer by the G. B. Markle Co. With the appointment of Chief Engineer J. B. Warriner, of the Lehigh Coal and Navigation Co., to succeed H. M. Crankshaw as manager of the Cranberry Creek Coal Co. and Alliance Coal Co., the office formerly held by Mr. Warriner was abolished and several other departments of the Lehigh Coal and Navigation Co. were merged. Mr. Crankshaw has postponed his return to England until he has completed an investigation of the Markle holdings on the North Side and has submitted a report showing the best means for extending the operations and increasing the output.

Wilkes-Barre—The Court of Luzerne has handed down appointments of mine inspectors' examining boards for Luzerne and Carbon Counties, and mine foremen's boards. The members of the mine inspectors' examining board succeed themselves for another term, being as follows: E. R. Pettebone, Dorranceton, consulting engineer of the Hudson Coal Co.; John M. Humphrey, of Wilkes-Barre, chief mining engineer of the Lehigh Valley Coal Co.; Cornelius McLaughlin, of Avoca; John Larkin, of Nanticoke; and Thomas Gallagher, of Lansford, practical miners. Few changes were made in the personnel of the mine foremen's examining boards, mainly owing to the removal of mine superintendents from one district to another.

Bituminous

Brownsville—The H. C. Frick Coke Co. is putting about 2000 beehive coke ovens out of blast this week in different parts of the Connellsville coke region and curtailing its coal output accordingly.

Savan—The tipple for the new operation of the Hess Coal Co. near here is in course of erection. The railroad siding has been graded and the public road changed, which was necessary for the erection of the tipple. A tramroad about one mile in length will be built from the mines to the tipple. Shipments will be made over the Buffalo, Rochester & Pittsburgh R.R.

Waynesburg—The Cumberland Coal Co. has purchased an interest in the J. C. Garard tract of coal land containing about 300 acres. The same company has purchased from Thomas B. Semans, of Uniontown, an interest in 19 tracts of coal land in this county for $154,876.53.

Mrs. Josephine Moore Heft, of Bridgeport, Conn., has purchased one-half interest in two tracts of coal in Jackson township from R. E. Kent and J. B. Gordon. Mrs. Heft also purchased a one-half interest in 79 acres in Gilmore township from E. C. Fordyce and Mrs. Louisa M. Fordyce.

WEST VIRGINIA

Fairmont—Construction work at the plant of the Domestic Coke Corporation, the new $5,000,000 coke byproduct concern, for the time being will be under the direct supervision of C. V. Critchfield, of Ohio, vice president of the concern. As, told in a recent issue of "Coal Age," construction work is to be resumed without delay and the installation of 60 byproduct ovens at a cost of $3,000,000 is to be rushed to completion.

Ansted—A revival of market activities has been reflected in the business of the Gauley Mountain Coal Co., whose plant is located at this place. Instead of operating its mines only three days a week the company is now able to employ its miners on an average of five days a week. At the same time the company has been able to increase its coke loadings and on a recent Sunday 22 car-loads of coke were pulled and loaded. In fact the coke output of the company is now limited only by the capacity of its ovens and the number of cars it can secure.

OHIO

Diamond—What is known as the old Kimberly mine is being reopened after being idle for a number of years. The mine is being cleaned up and it is expected to be in operation by June 1.

Bristol—The Huffman Mining Co., which has headquarters in Columbus, is busy on the work of opening a new mine on the Baltimore & Ohio R.R., near here. The company, of which T. J. Huffman is the head, has acquired 200 acres of land, on which a tipple has been built. It is expected to load coal in about 90 days.

INDIANA

Clinton—Miners of the Clinton coal field have agreed to work by the old time when the clock hands are moved forward Mar. 30. The miners say that a coal mine just before daylight is a very desolate as well as a dangerous place, especially on foggy mornings.

ILLINOIS

Carlinville—Trains on the Chicago & Alton R.R. are now run into Shoper, the new mining town opened by the Standard Oil Co. The crossing of the Chicago & Alton and the Northwestern has been completed and the first train ran Mar. 13 over the dam up to the mines.

Rutland—The tower of the Rutland coal mine has been destroyed by fire. The fire was not discovered until too late to save the structure, but the engine and boiler rooms nearby were saved. The loss is covered by insurance. The miners had not been working for several days as the boilers had been condemned. The company, the United States Coal and Coke Corporation, will rebuild.

De Soto—The Racine Co. has taken options on about 600 acres of land near De Soto and is boring holes in search of a big seam of coal. The company is really looking for the No. 5 seam of the famous coal mine at Murphysboro, and if it is found it will mean a large coal mining industry for De Soto, which now has a mine working 168 men, and another ready to start mining on a somewhat smaller scale. The Racine Co. has finished two holes and the drill is now at work on the third, which is to go deeper than the others. It is about 70 ft. to the bed of coal already being mined around De Soto.

Carlinville—The Standard Oil Co. mine on a recent day established a new record, hoisting 1212 loads, or 968 tons, which shows that the efficiency of the mine has increased greatly. While many mines in the state are idle, the Standard Oil mine here is running at full capacity. The Standard mine at Berry is producing coal and the machinery will soon all be in place for record-breaking runs. The Hunt Engineering Co., which has the contract for sinking the shaft, expects to turn over the mine to the Standard within a few days. Work is also progressing at the great mine at Shafer, and coal is being taken from both the main shaft and the air shaft in carload lots. When all the producing machinery is installed it is believed the mine will be the largest producer of coal in the world.

KENTUCKY

Whitesburg—It is announced here that the Southeast Coal Co., of Seco and La Viers, will put in a third mining plant on Thornton Creek, an important new territory being opened by a branch line of the Louisville & Nashville, a few miles out from Sergeant. It is reported that the work will soon be launched.

Central City—Two hundred miners have been thrown out of work and the operations of the Madison Coal Corporation, formerly the Central Coal and Iron Co., are at a standstill due to the loss of a big tipple by fire on Mar. 10. The blaze started from a defective flue in the weighroom, and spread rapidly. It is planned to rebuild the tipple at once. The Madison Coal Co. supplies considerable coal for the Illinois Central Railroad Co., with which it is allied, and is one of the most important company connections.

ARKANSAS

Midland—The first mine in Arkansas to be equipped with electrical undercutting machinery will soon be put in operation at this place by the Majestic Coal Co., of Fort Smith, which has recently been organized. The company own 290 acres of coal land and has leases on 300 adjoining acres in the Hackett-Excelsior vein, from which is mined some of the finest steam and domestic coal in the Southwest. The company will begin sinking its shaft not later than Apr. 1. It will be located one mile north of Midland No. 6 mine.

Personals

A. L. Learned has been appointed assistant to the president of the Lehigh Coal and Navigation Co., Lansford, Penn.

T. E. Barry, of Akron, Ohio, former union passenger agent, has been elected vice president of the Kendall Coal Mining Co. of Cleveland, Ohio, and has given up his connection with the Pittsburgh Coal Company.

James Conner, formerly mine foreman at the Freeport No. 1 mine at Dunbar, Penn., has been transferred to the Ferguson mine superseding **George Stockdale**, who has been granted a leave of absence for a much needed rest.

E. A. Holbrook, superintendent of the Urbana station of the Bureau of Mines, has been called to Washington to act as chief mining engineer of the bureau during the absence of George S. Rice, who is in Europe studying mine rehabilitation.

F. M. Sackett, of the Byrne & Speed Coal Co., Louisville, Ky., who served as Kentucky Food Administrator during the war, was the recipient of an unusual honor at an "after-the-war conference" in Lexington recently, being awarded a medal for distinguished service during the period. A medal was also awarded to E. W. Hines, chairman of the State Council of National Defense. The medals were awarded through the American Social Science Association.

W. D. Hamer, representative of the Electric Service Supplies Co., Philadelphia, Penn., has been transferred from his former territory in the Middle West to a southern territory with headquarters in Atlanta, Ga. He has been connected with the company for 14 years. Prior to 1905 he was employed in the stores and engineering department of the Lehigh Valley Coal Co. In 1917, with the courtesy and coöperation of the Nashville Railway and Light Co., he proposed and developed the first prepayment car operated in the South. Mr. Hamer also is inventor of the well known Keystone triangle arm.

Obituary

James M. Poyner, a prominent electrical engineer, for ten years connected with the Baltimore office of the General Electric Co., died, at the age of 37, of influenza, after an illness of ten days at Charleston, W. Va., on Mar. 3.

Charles E. Hurd, aged 33, formerly of Boswell, Penn., died in France in February of pneumonia. He had enlisted in the Engineers a year ago, and after a short training went to France. At the time of his enlistment he was employed by the Merchants' Coal Co. as a mining engineer.

William H. Yawkey, of New York City (formerly of Detroit), died Mar. 5 in Augusta, Ga. He was extensively interested in West Virginia coal properties, particularly in Boone and Logan Counties, where, it is said, in association with Colonel Freeman, of Huntington, 40,000 acres in all were owned. Mr. Yawkey was one of those prominently interested in the organization of the Big Creek Development Co., a large concern which recently passed into the control of others. He was at the time of his death one of the officers of the Pond Fork Coal Company.

W. R. Wilburn, general manager of the various mines in the Pennsylvania bituminous fields and the West Virginia field, of the Madeira-Hill Coal Mining Co., died at his late residence in Philipsburg, Penn. on Friday, Mar. 7, 1919. Mr. Wilburn was well known as an expert in mining, and was respected and liked by his fellow operators.

Mr. Fairbanks, of Chicago, Ill., for many years employed as the legal advisor of the W. P. Rend coal interests, died on Mar. 7. The Rends in particular, and the coal trade in the Middle West in general, feel that they have lost a valuable friend. Mr. Fairbanks was connected with the Rends for the last twenty-five years, and during that time has made a great number of acquaintances in the coal industry, both in the East and in the Middle West. Mr. Fairbanks' death is deeply regretted by a host of his friends, as his absolute reliability and his lovable character had endeared him to all who knew him.

Industrial News

Chicago, Ill.—The Roberts & Schaefer Co., engineers and contractors, are sending free of charge to anyone desiring it an exceedingly practical, vest pocket rule handy for scaling blueprints.

Mahanoy City, Penn.—The Lehigh Valley R.R., operating the Park Place Colliery, located near Mahanoy City, has placed into effect a new seven-hour per day working schedule for an indefinite period. A total of over 800 persons are employed at the mine.

Whitesburg, Ky.—A strike at the mines of the Stoner-Elkhorn Coal Co., in the Beaver Creek section, has been settled satisfactorily to the company. One of the reports stated that an increase in the wage scale was made, but it is understood that the strike was over operating conditions, and not over the wage question.

Birmingham, Ala.—The tipple of the Empire Coal Co. at Empire, Ala., will be completely remodeled and equipped with car hauls, revolving dumps, Marcus picking table screen and loading boom, the installation of this equipment having been contracted for with the Roberts & Schaefer Co., of Chicago.

Chicago, Ill.—The Chicago Pneumatic Tool Co. announces that it has moved its Detroit office from 236 Hancock Ave. to 502 Farwell Building. The Boston office of the company has been removed to 182 High St., while an office and warehouse has been opened at Tulsa, Okla., and at El Dorado, Kansas.

Buffalo, N. Y.—J. H. Hillman & Sons Co., of Pittsburgh, are opening an office at 428 Prudential Building, with Thomas B. Dunbar, formerly with B. Nicoll & Co., in charge. J. Frank Pinner, an old Buffalo coal man, has taken an office in his own name at 300 Prudential Building. J. J. Eagan has moved his coal office to 1224 Prudential Building.

Louisville, Ky.—The mine operators of the Tennessee Central District have made a plea for a reduction in the present coal freight rates to Sheffield, Tuscumbia and Florence, Ala., from $2.20 to $2, to accord with rates from the Coal Creek and Glen Mary sections of Tennessee. This plea will be heard in Louisville on Mar. 26, when the Louisville District Freight Traffic Committee, of which J. M. Dewberry, is chairman, will hold a session. At this same session grain, lumber and other rates will be examined.

Columbus, Ohio—According to a recent statement of John Moore, president of the Ohio organization of miners, 15,000 miners in Ohio have been idle since Jan. 1. This is almost one-third of the total miners, as it is estimated that there are 50,000 miners in the state. Moore attributes the lack of work to the suspension of many business activities, the attitude of the U. S. Railroad Administration in not buying Ohio coal and in the fact that the markets of Indiana and Michigan have been lost temporarily. No relief is looked for until the opening of the lake trade.

Charleston, W. Va.—Valuable coal deposits in Fayette and Nicholas Counties will become accessible to the market through the building of the Gauley & Eastern Ry., which is now nearing completion, the road having cost about $450,000. The new road will be operated between Gauley Bridge and Belva—a distance of six miles—and will connect with the Kanawha & Michigan Ry. at Belva. It will be ready for operation by the middle of April. The Kanawha Collieries Co. and the Beech Glen Coal Co. expect to begin operations about that time.

Kansas City, Mo.—An increase of 10c. a ton on coal shipments from Springfield, Mo., to Kansas City, which is scheduled to go into effect soon, will be protested by commissioners of Kansas City, Kan. The increased freight rate was brought about by the Kansas City district freight traffic commission. A resolution of protest has been drawn up, stating if the rate is put into effect Kansas City and vicinity will pay from 10 to 50c. a ton more for coal than at present and more than any other neighboring districts.

Chicago, Ill.—The Sullivan Machinery Co. has established a branch sales office and warehouse in Mexico, at Edificio Oliver No. 3, Mexico City. Joseph F. Bennett, for a number of years sales engineer in Mexico, associated with the El Paso branch of the company, has been placed in charge of the Mexico City office. Sullivan air compressors, rock drills, hammer drills and drill sharpeners will be maintained in stock, together with parts and supplies. The office will serve central and southern Mexico, and that part of the states of Sinaloa, Durango, Coa Huila and Tamaulipas, lying south of the 26th parallel of latitude.

Jefferson City, Mo.—A bill has been introduced in the House here amending the Missouri anti-trust laws so as to permit coal dealers to arrange, under the supervision of the Attorney General of the state, the cost of conducting the retail coal business. The Attorney General will then decide what a fair margin of profit is. This is practically a continuation of the Government supervision of the distribution of coal, only it will be under the state instead of the Federal Government. An amendment of the anti-trust law has been introduced at the request of E. J. Wallace, who was advisor to the St. Louis Fuel Committee, and the feeling here is that it will go through.

Charleston, W. Va.—Five mine rescue stations will be established in West Virginia by the Department of Mines at a cost of $20,000. The location of such rescue stations has not yet been definitely decided upon, the department wishing to consult the operators of the state with a view to having such stations placed where they will be the most useful and serviceable. Preliminary plans indicate that not only will the coal men of the state fully coperate with the department in this matter, but that they will actively aid in the maintenance of the stations. Some have even gone so far as to promise that they will furnish a part of the equipment, such as ambulances, etc.

Louisville, Ky.—Western Kentucky coal operators who are alarmed over the efforts of some of their associates to reduce coal prices, have received word that the mine workers, through their unions will oppose any attempt toward reduction. The miners naturally do not favor reduced prices because they known that price reduction will mean wage reduction. The unions have agreed that their men will not work for any operator who lowers wages. On the other hand, western Kentucky operators are planning to abide by the prices indicated as a standard by the Director-General of Railroads. Under this plan screen coal is selling at $2.60 and mine-run at $2.35. According to information gathered in Louisville, it is generally believed that miners throughout the state are well united and that they will strike if there is any attempt at wage reduction.

Du Quoin, Ill. The annual meeting of the Southern Illinois Mine Superintendents Association was held in this city Saturday, Mar. 8. An elaborate banquet was given the delegates at the St. Nicholas Hotel, after which many splendid addresses were made by various state officials and others. James Dunn, of West Frankfort, president of the association, was chairman of the meeting, assisted by Bruno Schulter, of Sesser, who is secretary-treasurer. Dr. F. C. Honnold, of Chicago, secretary-treasurer of the Coal Operators' Association of Franklin, Williamson, Saline and Perry Counties, in the principal address of the meeting expressed the need of better screening and cleaning of southern Illinois coal and stated that if this was done the market for the coal would be much better. Joseph C. Thompson, formerly state mine inspector, and now director of the Department of Mines and Minerals, spoke on "Safety in Coal Mining." Other addresses were made by Walter S. Burris, former state mine inspector, James Forester and Theodore S. Cousins.

MARKET DEPARTMENT

Weekly Review

Coal Market in General Lacks Snap—Half Time at the Mines May Lead to Labor Troubles—Consumers Who Hold Off in Their Buying May Have Cause for Regret Later—Anthracite Situation Still Poor

THOUGH signs of activity are by no means wanting, the coal market in general lacks snap. The brakes are still being applied to industry; and until the wheels are unlocked the coal mines perforce must continue to work only half time, and mine employees must continue to complain that the shorter week does not enable them to meet the high cost of living (if they do not take it into their heads to evince their dissatisfaction through the well known medium of the strike).

Shortsighted consumers are still of the belief that coal prices will go lower if they hold off their purchases for a while longer, in spite of the fact that every grain of common sense they possess should influence them to the contrary. If labor troubles materialize at the mines, and the possibility is by no means remote, there are going to be many consumers who will wish they had bought coal while the buying was good. Prices cannot come down. The closing of a great number of mines should be proof conclusive that no indiscriminate price-cutting will be practiced by the operators. Either they do business at a reasonable profit or they do no business at all.

The weekly production of soft coal is still hovering around the eight-million-ton mark, only 8,058,000 net tons being the output for the week ended Mar. 8. For the coal year to date the total tonnage mined amounts to 533,579,000 net tons, which is but 16,613,000 net tons greater than the output for the same period of the previous coal year.

As yet the anthracite trade has not reacted to the announcement that prices would not go lower on Apr. 1. Dealers and consumers will doubtless commence to lay in stocks before May 1, when an increase of 10 cents a ton goes into effect. The only demand for anthracite seems to center around stove and nut coal, while a fair amount of pea is also being sold. Domestic demand there is none, and it is natural to expect a season of the keenest competition in the steam trade.

Anthracite production during the week ended Mar. 8 is estimated at 989,000 net tons, which brings the output for the coal year to date to 88,111,000 net tons.

WEEKLY COAL PRODUCTION

The production of bituminous coal during the week ended Mar. 8, is estimated at 8,058,000 net tons, and is approximately the same as the output of Mar. 1, which was estimated at 8,085,000 net tons. The current week's output, however, falls 3,559,000 net tons below the output during the week of Mar. 9, 1918. The daily average per working day during the week of Mar. 8 is estimated at 1,343,000 net tons, as against 1,815,000 net tons for the coal year to date and 1,758,000 net tons for the same period of last year. Total production for the period Apr. 1, 1918, to Mar. 8, 1919, is estimated at 533,579,000 net tons, and is but 16,613,000 net tons in excess of the output for the same period of last year.

Anthracite production during the week ended Mar. 8 is estimated at 989,000 net tons, as compared with 1,102,000 net tons during the week ended Mar. 1, and 2,099,000 net tons during the same week of 1918. The daily average per working day is estimated at 165,000 net tons, and is considerably lower than the average production per working day for the coal year to date, estimated at 300,000 net tons, and for the 1918 coal year, ended Mar. 8, estimated at 317,000 net tons. Production of anthracite from Apr. 1 to Mar. 8 is now estimated at 88,111,000 net tons and is 5,160,000 net tons below the production for the same period of last year.

Carriers' reports for the week ended Mar. 8 show increased loading in central Pennsylvania, Tennessee and Kentucky, and in the central and far west states. All other districts report a slight falling off compared with the week of Mar. 1. For the calendar year to date, loading in all districts is considerably behind that of last year.

Shipments of bituminous coal to New England from the tidewater harbors during the week ended Mar. 8 are estimated at 169,384 net tons, as compared with 128,885 net tons during the week of Mar. 1. The improvement occurred at New York, Philadelphia and Hampton Roads, no tonnage being loaded at Baltimore either this week or last. Shipments by rail were not reported for the week of Mar. 8.

Shipments of bituminous coal from tidewater harbors to all points during the week ended Mar. 8, estimated at 454,543 net tons, declined considerably compared with the tonnage loaded during the week ended Mar. 1, estimated at 567,782 net tons. While decreases occurred at all harbors, the decrease at Hampton Roads was slight, amounting to approximately 6200 net tons.

The production of beehive coke in the United States, during the week ended Mar. 8, is estimated at 440,118 net tons, and was but slightly in excess of the production during the week ended Mar. 1, estimated at 438,832 net tons. The current week's production, however, was far below that of the week of Mar. 8, 1918, when the output reached 595,992 net tons. Pennsylvania and West Virginia were the only states in which production during the week of Mar. 8 exceeded the output of Mar. 1, while all states report a lower output than was recorded during the corresponding week of 1918. The average production per working day during the week ended Mar. 8, is estimated at 73,353 net tons, as compared with the average production per working day of 82,419 net tons for this calendar year to date, and 90,769 net tons for the same period of last year.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running considerably less than for the same week of 1918. Road sales for at once delivery are not up to the large volume of the corresponding period a year ago. Salesmen are now getting on the road with Fall lines and an excellent advance business is anticipated. More merchants were in the market, buying for their immediate needs. Retail business continues most satisfactory. Collections are normal.

The Iron Age—New business has come in in the past few weeks at only a fraction of the February rate of operations. With most independent companies March orders have not been over 20 per cent of capacity. It is also to be considered that in some districts, notably Pittsburgh, large rollings for stock were made in January and February. It is thus to be expected that output will fall off in March and April, with progressive reductions in working forces at steel works and rolling mills.

American Wool and Cotton Reporter—The wool market seems to be particularly strong in pulled and scoured wools, as shown by the demand at the Government auctions on Mar. 10 and 11. It is evident that mills have received orders and are endeavoring to purchase wools with which to fill these orders. Activities in the Middle West on the new clip have already begun, as it is reported that a large Boston operator in fleeces has purchased wool on the sheep's back at 50c. per pound.

Dry Goods Economist—Two reasons are given for the continued prosperity of the dry goods trade: First, the great majority of the people are still in need of new goods, new clothes or new furnishings for the home, and are able to satisfy that need; second, the approach of Easter, now only five weeks away, has given emphasis to this need and thereby stimulated the movement of goods. Labor unrest continues in many centers and has hampered the production of various commodities and their transportation.

Bradstreet's—While inclement weather and bad roads are a bar to seasonal trade expansion and price uncertainties still hold back buying and industrial operations, the week's report summarized is one of moderate but still definite progress toward better things. Favorable features of the week are the continued strength of the securities markets, the settlement of shipyard strikes and the resumption of considerable textile machinery in New England, although at below maximum rate, the net result being a reduction in the total number of unemployed.

Atlantic Seaboard

BOSTON

Improvement very gradual. More confidence in prices. High range on quality grades a feature. Contracts being closed, but for small tonnages. Coastwise freights slowly reduced to working basis. Hampton Roads shippers watchfully waiting. Pennsylvania coals now accessible by water. Scattered inquiry for April shipment. Anthracite continues dull. Only hand-to-mouth buying except on special grades. D. & H. plans. Rumored that Reading fleet will be restored to Philadelphia.

Bituminous—A slow but steady improvement is noticeable throughout the trade. There is today an interest in quotations that has not been manifest since the summer of 1917. From all parts of the territory there are inquiries for coal in small lots, a condition that usually forecasts a broadening market later. Naturally, under present circumstances, this renewal of inquiry is almost wholly confined to coal by the all-rail route and operators are keeping in close touch with developments from day to day. Several operations where the output is favorably known in New Eng-

land have increased their tonnage over the January and February marks, and from all standpoints steam coal is in better request.

It follows as a direct result of such a market that buyers are listening more respectfully and that there is distinctly more confidence in prices than at any time since Nov. 11. It is being impressed upon steam-users that there is not really a very large tonnage of high grade coals available for New England, and with all the uncertainty over tidewater prices it is easy to see that some may over-stay, if buying is postponed to too late a day. The amount of coal in storage here is still very large, but inroads are being made, and there is in the aggregate quite a considerable market from plants where there is a desire to get superior coal to help burn some of the mongrel lots shipped last season. At $2.95@3.05 there is not much murmuring even on second-rate coals, provided they are of known quality, and something of a tonnage on "B" and "D" coals has been placed at about these figures.

One outstanding feature of the all-rail market is the price level that No. 1 Pennsylvania coals now command. Several sales have been reported on the choice grades from Wilmore Basin at $3.40@3.50 per net ton at the mines, and one quotation of $3.58 was heard the past week. Some grades from Clearfield County are being sold down to $2.35 per net ton, but as a rule the inquiry for these is less active. The gas coals, even of those of highest grade, are making only light shipments, so well stocked are all the plants in this territory. An energetic effort is made to place gas slack at $2.30@2.40, but the present market affords little response.

What contracts have actually been closed are on the $2.95@3.10 basis for coals from Somerset and Cambria Counties. So far, however, the tonnages have been small, for the larger buyers will not be ready to enter the market until May or June, at the earliest. A few consumers who have usually bought Pocahontas and New River through Boston and other rehandling plants have made purchases all-rail, but the greater number are still awaiting developments on the tidewater situation.

In respect of coastwise freights the situation is settling down quite rapidly. A week ago $2.50 was considered the rate from Hampton Roads to Boston, but at this writing it is virtually admitted that $2 is all the market will pay, even on bottoms owned or operated by the Shipping Board.

The Hampton Roads agencies are following a policy of watchful waiting for the present. There is no buying of any consequence today, even on the prospect of $2 freights, for it is felt that by the time New England industries are ready to enter the market on any comprehensive scale that marine freights will have settled down to something like a workable basis. The tonnage for New England is still very light, and on the part of rehandlers here there have been some extraordinary efforts to move coal inland to make room for the few cargoes that are coming forward each week.

One of the recent developments of the Boston market is the reappearance of Pennsylvania coals by water. This is induced by the relatively low rates that now prevail on barges from New York, $1.25@1.35 being the rate. The New York harbor strike has somewhat affected the movement of this transportation, but the demand here has not been urgent enough to cause any stiffening in rates. Several cargoes have lately been sold at $6.50 per gross ton alongside Boston, the coal being furnished from Pool 10, and one sale is reported at $6.10. There is at least a scattering inquiry for April shipment, especially from some of the utilities who have not yet seen fit to open the subject of contract. The steam railroads are making practically no purchases, their supply in storage being still very large. The Boston & Maine is understood to have upward of 350,000 tons in storage, or more than 90 days' reserve, at the present rate of consumption.

Bituminous prices at wholesale are about as follows, f.o.b. mines and at loading ports, per gross or net ton as designated:

	Clearfields	Cambrias & Somersets
F.o.b. mines, net tons	$2.15@2.75	$2.80@3.50
Philadelphia, gross tons	4.20@4.90	5.00@5.55
New York, gross tons	4.50@5.25	5.35@5.95
Alongside Boston (water coal), gross tons	6.10@6.85	6.90@7.80

Georges Creek is quoted at $3.20 f.o.b. mines per net ton.

Pocahontas and New River are unchanged at $4.70@5.25 f.o.b. Norfolk and Newport News, Va., for spot coal, the former Governmental differential of 35c. in favor of New River being fairly well maintained. Alongside Boston the present gross ton range would be $7.15@8.10.

Anthracite—The recent firm announcement that no reduction in prices at the mines would be effective and that on the other hand prices would be advanced by the companies 10c. per ton per month up to and including Sept. 1 has been used as an argument to get coal forward as fast as it could be had, but the retail dealers are not responding. At tidewater there is a strong feeling that freights will have to be reduced from the present arbitrary level on boats under the jurisdiction of the Railroad Administration, and all-rail there is a tendency to make haste very slowly. There is a very natural desire to get cleaned up of all the poor coal still remaining from last year's shipments, and then again local price situations, as left by the different fuel committees, are in such ragged shape that in many communities there will not be the inducement to take in coal during the spring months. In consequence here is very little buying.

Considerable interest has been aroused here over the rumor that the Reading fleet will be restored to Philadelphia.

NEW YORK

Anthracite market stronger since price announcement. Dealers in the market for coal, but harbor strike delays deliveries. Dealers expect improved conditions. Dissatisfaction reported among miners. Steam coals shorter. Embargoes prevent local docks being flooded with bituminous. Buyers ready to buy when necessary to refill bins. Line trade active and prices steady.

Anthracite—There is stability in the situation now that the coal trade knows what to expect in the way of prices. While everyone seemed to know that there would not be any reduction on Apr. 1, and that there would follow five monthly advances of 10c. each, buyers did not feel sure of themselves and hesitated to make any more purchases than was absolutely necessary, although many wholesalers had agreed to bill coal at the April prices.

The full effect of the price announcement has not yet been felt in this market because of the marine strike, but the ten-day tie-up of the coal boats and tugs has resulted in retail dealers supplies being reduced to less than a week's supply, and much less if the weather becomes suddenly cold. Wholesalers look for a decidedly brisk market when conditions in the harbor become normal, but which may not continue longer than it is necessary to refill the dealers' bins.

Inquiries here indicate a much better situation, not withstanding slow deliveries. Orders are being received in better shape and shippers said similar conditions existed in other sections of the country. From the West come reports of the lack of anthracite and the desire of consumers for a resumption of conditions as they existed before the war and prior to the supervision of the Fuel Administration. It is expected there will be a heavy demand for hard coal from those sections and shippers look for a busy season.

The slow production due to the unusual winter and the closing down of many washeries has caused a shortage of coal at the docks, but not to an extent to cause any alarm if there should come a sudden heavy demand.

More anxiety is felt over the anthracite steam coal situation than over the domestic sizes. Every householder has at least some of the latter sizes on hand, but users of the steam sizes, particularly buckwheat, must receive a certain tonnage daily, especially the big office buildings. With many of the mines and the washeries closed at least three days a week these coals have become scarce and some shippers are showing anxiety as to the tonnage they may receive in the future. There are some wholesalers who believe there should be a reduction in the prices for these coals if efforts are to be made to regain some of the trade taken over by bituminous coal sellers because of the lower price at which the latter can be obtained.

There has been some inquiry regarding contracts for the anthracite steam coals, particularly barley, quotations on the latter ranging from $1.80 to $2 for the better grades.

Current quotations, White Ash, per gross tons, f.o.b. Tidewater, at the lower ports are as follows:

	Mine	Company Circular
Broken	$5.95	$7.80
Egg	5.85	7.70
Stove	6.10	7.95
Chestnut	6.20	8.05
Pea	4.80	6.55
Buckwheat	3.40	5.15
Rice	2.90	4.65
Barley	2.40	4.15

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates.

Bituminous—Movement of coal has been slow here because of the harbor strike, but trade along the line has been active and a much better market exists. Prices have had but little effect upon conditions. Salesmen report that the reason for a not more active condition is either no work in the factories or full bins.

Buyers are realizing the futility of expecting cheaper coal with the present cost of production and seem willing to make purchases if they can secure the coal wanted. Along the line consumers are holding fast to the grades wanted and in most cases refuse any substitute.

The ending of the trouble in the New York harbor is expected to stimulate trade. Many bins are nearly empty as a result of the strike and manufacturers are becoming uneasy.

The placing of embargoes on shipments to this port has saved the docks from being over-stocked; nevertheless salesmen say the line trade has been able to absorb nearly all the coal produced and that the mines are working a trifle steadier than they did a few weeks back.

While there have been numerous inquiries concerning contracts the closing-up process has been slow. Buyers are hesitating about signing up for the twelve months ahead because they feel prices are sure to come down. To offset this it is reported some operators are including in their contracts a clause providing for a readjustment of prices at certain periods.

Quotations on various grades of bituminous coal for spot and contract delivery, are:

	Spot	Contract
South Forks	$2.90 to $3.50	$3.10 to $3.50
Cambria County (good grades)	2.80 to 3.00	2.95 to 3.00
Clearfield County	2.65 to 2.95	.....
Reynoldsville	2.65 to 2.95	2.85 to 3.00
Quemahoning	2.85 to 3.10	2.95 to 3.10
Somerset County (best grades)	2.80 to 2.95	2.95 to 3.10
Somerset County (poorer grades)	2.50 to 2.75	2.75 to 2.95
Western Maryland	2.50 to 2.75	2.65 to 2.85
Fairmont	2.10 to 2.35	2.35 to 2.50
Latrobe	2.25 to 2.40	.....
Greensburg	2.35 to 2.40	.....
Westmoreland ¾-in.	2.60 to 2.75	2.65 to 2.75
Westmoreland run-of-mine	2.40 to 2.65	2.40 to 2.65

PHILADELPHIA

Anthracite continues dull. New printed price circular sent out. Announcement fails to improve conditions. Much discussion as to permanence of price plan. Consumers hold back, still expecting reduction later. Credits becoming a problem. Retail price-cutting grows. Pea difficult to handle. Some activity in steam-coal contracting. Bituminous quiet. Strong demand for high-grade coals. Increased contracting. Railroads cut down fuel supplies.

Anthracite—It is not likely that the operators expected the early announcement of April prices would bring a rush of March business. They are probably too familiar with conditions to believe the coal-buying public would take kindly to a new schedule that does not permit the usual spring reduction. While the selling forces had endeavored for weeks to prepare the dealers in advance, by intimating what the new prices would be, the circular issued by the largest operating company, which was dated Mar. 10, but for some reason was held back and not received by the trade until the morning of the 13th, came as somewhat of a shock. This was probably because the price question was thereby squarely put up to them to explain to their trade. To put the responsibility entirely on the operators does not seem to satisfy their customers, and they are having a difficult time explaining "why."

That the circular referred to quotes prices for April and May only leaves room for doubt in many minds as to the summer schedule. It quotes the present March circular for April "subject to an advance of 10c. per ton effective May 1." In other words, the circular fixes the wholesale prices until June 1. Before that time many things might happen to prices. To begin with, there is much discussion as to miners' wages, it being firmly fixed in the minds of

all coal interests that no price reduction can be expected with wages fixed as at present. Certainly so long as conditions only warrant working the mines three days a week there can be no reduction.

Another cause of anxiety to the retailer is the question of credits. While the dealers can hardly expect to continue on the cash basis they enjoyed the past year, they now fear that when they try to force sales they will be expected to place accounts on their books. Some call attention to the fact, for instance, that three cars of coal often cost $1000, and with daily settlements for the freight the business calls for such a large investment that they cannot extend credits as in the old days. It is possible that the larger buyers will this season call upon the shippers to be lenient and not insist upon 30-day settlements. Right at this time it is known that all shippers have more money standing on their books than at any time during the past two years.

We hear that some of the more prominent dealers are considering asking the shippers for coöperation in their efforts to eliminate the price cutters. It seems they would like the producers to treat with indifference the orders of a few who have become notorious in this respect. It is a difficult matter to handle in that way, and we do not really expect to see anything of consequence come from the movement. This week one dealer announced his pea coal price as $7.75, or $1.30 per ton below the regular rate.

The only demand for sizes seems to center around stove and nut, with a fair amount of egg asked for. Pea continues to be a most serious problem. The dealers continue to have large stocks of it on hand with hardly any movement at all to their customers. They are still hoping for some cold days throughout March and April, with the idea that they may thus be able to move some of their stock. It is becoming an even greater problem with the operators, for while they can move the other sizes fairly well on the restricted working time, they are hard put to it to get rid of pea.

No action has been taken in regard to prices on steam sizes, nor on broken, as they are not mentioned in the only circular that has been issued and we take it for granted that prices are to remain unchanged for the present. With a poor domestic market we expect to see a season of the keenest competition ever experienced here for the steam trade. We have heard already that one of the largest companies is making up contracts on the steam sizes, although they have not stated publicly the prices which they expect to get. Apr. 1 is the usual contracting season for them, and we think they will pursue the practice of making up the contracts for their old customers in advance and then presenting them for their decision.

Due to the short working time there has been some difficulty in filling buckwheat orders by the larger companies, although some of the independent operators continue to offer this size around $2.75. The big companies are also going into their storage yards at times for rice coal in order to fill some of their orders.

The price per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$5.95	$7.30	Buckwheat	$3.40	$4.45
Egg	5.85	7.20	Rice	2.90	3.80
Stove	6.10	7.45	Boiler	2.70	3.70
Nut	6.20	7.55	Barley	2.40	3.30
Pea	4.80	6.05	Culm	1.25	2.15

Bituminous—The bituminous trade is simply drifting along with the hope that industrial improvement may come to the rescue of the trade. As it now stands it is not believed that the mines on an average are making 30 per cent. of full working time.

An interesting feature of the trade lately has been the inquiry for high-grade coals from New England consumers. This is due to the fact that boat freights are so high from southern ports that it makes the use of coal from that territory almost prohibitive. Due to this condition there has not been the least trouble in maintaining the full price on the good coals here and tonnage is actually scarce.

If anything there has been an increase in contract business, which is being closed at figures running from $2.90 to $3.35 per net ton. Practically all this business has been closed to date as of Apr. 1 and some also May 1.

There is very little activity whatever in the spot coal market, although on low grade coals there are plenty of offerings with very few sales made. Sometimes there are fairly heavy price cuts to move occasional cars.

There is very little new tonnage going to the railroads for fuel, as the concerns who had contracts with them have shipped so heavily that the roads have been compelled to stop shipments in numerous instances.

BALTIMORE

New elements of strength noted in the bituminous market. Inquiry line grows steadily and prices are a little firmer. Hard coal business one largely of speculation as to the next spring schedule.

Bituminous—While general business in this section still wavers as to its scope for the future, awaiting apparently for some settlement of the governmental railroad control and other big reconstruction problems, there is a growing evidence of confidence for the days to come shortly and with it a resumption of plans that mean coal consumption. Then a number of plants are running low on supplies put in heavily in the months past, and the total result is that there is a steadily growing line of inquiry in practically all the coal offices here.

In the majority of cases the call is for high grade coal, this requisite being considered above that of price where the latter is near the old Government maximum. Of course there are some consumers gunning around for good coals at very cheap prices. Most of these have been encouraged by being able to pick up some coal at sacrifice. This was coal caught on demurrage and does not by any means represent the market.

The general run of trading here on fair to good coals was on a mine basis at tide around $2.65 to $2.85. Specialized coals in some cases sold higher. During the week the trade largely discussed the conference at the Hotel Shoreham, in Washington, between coal shippers and Government officials, concerning the future of the Tidewater Exchanges. Some interests have been for their complete abolition and some for their maintenance in full. Others favor some mid-way arrangement that would protect shippers against excessive losses on a high demurrage short-free-time basis where there was no interchange of coal at tide. The Maryland Jobbers' Association sent delegates to the conference to contest a complete wiping away of the pool on Apr. 1.

Anthracite—The hard coal men are merely marking time. Sales are light and the public on the one side awaits lower prices in the spring and the coal men await a new schedule which it is confidently expected will be at least as high as the present. Local newspapers have warned that little cut is expected and point out the considerable difference in the present retail prices and those of last April. Coal men point out that the public and the daily press fail to consider that the Government forced the present price by jumping freight rates and miners' wages, and that the coal men are getting no more, and in some cases less, than they did under the old schedules.

Lake Markets

PITTSBURGH

Contract season brings little activity. Tentative contracts considered. Production remains light. Prices well maintained.

The near approach of the conventional contract season for coal has brought very little increase in market activity. With few exceptions buyers are disposed to hold off and if they evince any willingness at all to enter into negotiations it is usually on the basis of seeking some other arrangement than the usual one of buying coal at a flat price for the twelvemonth. The course that operators had mapped out for themselves, that of simply adhering to recognized prices, is a very simple one, and there seems to be no disposition to depart from it. There is nothing out of line, however, in making an arrangement whereby coal will be shipped regularly and billed at the recognized market price from time to time.

Current demand for coal has not noticeably improved, as a whole. While stock piles have been running out there is on the other hand lighter consumption in several direction. The domestic demand, of course, is about over. There has not been much winter in this district and the time for wintry weather is now past. As to the steel industry's coal consumption, it is decreasing materially from week to week although it is still quite heavy, probably about 75 per cent. of normal. The independent steel makers are not doing as well as that, but the Steel Corporation subsidiaries are doing better. They are not a coal market factor, however. Pittsburgh district production continues at 25 to 30 per cent.

The market remains fairly steady at $2.25@2.35 for steam mine-run, with 1¼-in. domestic at but little more, while good grades of ¾-in. gas coal run $2.50@2.70, depending on grade, all per net ton at mine, Pittsburgh district.

TORONTO

Demand continues very quiet. Dealers and consumers well stocked up. Few shipments coming forward. Industrial readjustment slow.

The demand for coal of all grades remains very light, as owing to the remarkably mild winter most consumers who had laid in stocks still have supplies on hand. The yards are well stocked up, and but few shipments are now being received from the mines. The readjustment of plants lately engaged in the production of munitions to commercial work is proceeding but slowly, so that there is no noticeable increase in the call for bituminous. Smokeless coal is practically off the market, but dealers anticipate a good demand for it later in the season.

Quotations for short tons are as follows:

Retail:

Anthracite, egg, stove, nut and grate	$11.50
Pea	10.00
Bituminous steam	8.25
Slack	7.25
Domestic lump	10.00
Cannel	13.00

Wholesale f.o.b. cars at destination:

Three-quarter lump	6.25
Slack	5.25

BUFFALO

Coal still waiting for other business to move. Production exceeds sales. Bituminous mines idle most of the time. Loading anthracite into lake vessels.

Bituminous—The trade still languishes. Consumers appear to be agreed that they can reduce prices if they hold off. Some of them refuse to buy because they have a supply, often exposed to the weather, and they want to use it up as soon as possible. The shippers find little satisfaction in urging them to buy and report that it is useless to offer coal at a reduced price. The consumption is not heavy enough to force much buying and so there is not much to do but wait.

The bituminous prices are nominally unchanged. There is some cutting, but it is not as extensive as might be expected and does not affect the general firmness much. Quotations: $4.65 for thin-vein Allegheny Valley all sizes, $4.45 for Pittsburgh and No. 8 lump, $4.20 for same mine run and slack, $5.65 for smithing and smokeless, $5.60 to $6.10 for cannel, all per net ton, f.o.b. Buffalo.

Anthracite—The demand is light, especially since all fear of severe weather is now past. The consumer will no doubt buy some against the coming winter before May 1, but that is too far away to worry him now. The shippers are still finding coal coming out of the mines faster than they can sell it and are storing it wherever they can. Quite an amount of demurrage is said to have been paid at various points.

The prospective dullness of the lake trade is not favorable to a good movement. Vessels are taking cargoes here, as they often do in March, but as a rule they insist on sailing at their own option, instead of the option of the shipper, which means that the sailing may be delayed some time after the general opening of navigation. There does not appear to be any market for the coal at upper-lake ports at present.

The city prices for anthracite remain as follows:

	F.o.b. Cars, Gross Ton	At Curb, Net Ton
Grate	$8.55	$10.25
Egg	8.45	10.20
Stove	8.70	10.10
Chestnut	8.80	10.50
Pea	7.00	9.05
Buckwheat	5.70	7.75

With an addition of 25c. per ton to the car price for loading on lake vessels.

CLEVELAND

Several lake shippers in the No. 8 district are preparing to operate their properties full time beginning Apr. 1. The steam coal market, generally speaking, continues extremely dull, with slack perceptibly weaker.

Bituminous—Stockpiles at the lower industrial plants in northern Ohio are beginning to look ragged, but plant executives appear deaf to all advice that they be careful lest when they seek to restock coal be less plentiful than it is today.

The attitude of users is that when the time to replenish comes prices surely will be no higher than today, and that the wise policy is to work off as soon as possible all the low-grade coal they were compelled to accept last summer. As a consequence, 40 per cent. operations at eastern and southern Ohio mines continue to be the answer.

Slack is growing weaker, and may be had for $4.55 to $4.90, delivered, short ton, in Cleveland. Mine run for both the No. 6 and No. 8 grades is holding firm at $4.55 and $4.90, respectively. The retail trade continues to do obeisance to the continued warm weather.

Anthracite—Like domestic grades of bituminous, anthracite is sluggish. The cold spell of last week, which by now has succumbed to a mild wave, forced consumers to dig into their piles but has brought no buying.

Lake Trade—Lake coal shippers have been definitely informed by the Federal Railroad Administration that the present three-day demurrage rule has been abrogated and five days' free time will be allowed on cars at Lake Erie ports, with demurrage beginning the sixth day at only $1 a day instead of $3. This clears the boards for the 1919 lake trade, which is fast getting into full swing. Operators and railroad representatives have agreed that while general pooling of cargo coal will be discontinued, shippers will pool coal voluntarily where possible in order to release cars. The Ore and Coal Exchange, with headquarters at Cleveland, which conducted the 1918 lake pool, will be continued, with Herman M. Griggs again manager.

Coal is coming forward to Lake Erie ports in good shape, and due to the congestion of lake steamers at Buffalo, to hold winter storage grain for the Government, cargoes are in excess of carriers. Four steamers are being loaded at Cleveland and several at Buffalo and Ashtabula for the first trip to the head of the lakes.

Quotations on coal in Cleveland in net tons, delivered, are as follows:

Anthracite:	
Egg	$10.80 to 10.95
Chestnut	11.00 to 11.10
Pocahontas:	
Lump	7.50
Mine-run	7.20
Domestic Bituminous:	
West Virginia splint	7.15
No. 8 Pittsburgh	6.35
Massillon lump	7.10
Steam coal:	
No. 6 slack	4.55 to 4.60
No. 8 slack	4.90 to 4.95
Youghiogheny	4.95 to 5.05
No. 8, ¾-in.	5.45 to 5.55
No. 6 mine-run	4.55
No. 8 mine-run	4.90

DETROIT

Despite a slight stimulus in retail domestic lines due to colder weather the Detroit coal trade is generally inactive.

Bituminous—Only a small degree of activity is discernible in the bituminous division of the coal trade in Detroit. Neither the users of steam coal nor the retail dealers seem willing to give receptive attention to offers of additional stock at this time. Jobbers say few of the buyers show any disposition to consider contracts at present, though customarily the matter of contracts is of large interest at this period of the year.

Indifference of the Detroit buyers is ascribed to the large stocks of bituminous that are still filling storage yards of the retailers and appear in enormous reserves of the steam plants. Some of the latter are said to have sufficient coal in reserve to provide for normal needs until nearly July. Low grade stock forming a substantial part in many of these reserves is chiefly held responsible for fires that have occasioned considerable inconvenience and annoyance to the owners.

The wintery temperature of the early part of the month was productive of larger demands on retail dealers from household consumers, most of whom, however, were asking for anthracite coal or coke, while the dealers would more gladly see sales of the abnormal accretions of bituminous coal that were put in when the Fuel Administration regulations seemed to make that form of coal the only kind that would be available for most of the household consumers. Many of the retailers will be obliged to carry over large stocks into the summer, which with a more plentiful supply of anthracite next winter may prove difficult to move even then.

Jobbers say the last prices made effective by the Fuel Administration are still being maintained on practically all the business they are receiving through occasional sales, with demurrage impending, show a slight shading of price.

COLUMBUS

A slight improvement is reported in the demand, especially for steam grades. Domestic trade is rather quiet, due to the continued warm weather. Prices are somewhat unsteady although cutting is not as common as formerly.

The principal feature of the coal trade in Ohio is the approaching contract period for steam tonnage. Operators and jobbers alike are wondering what will happen when Apr. 1 rolls around. That is the date for a large number of steam contracts to expire and consequently there is much question as to the future. It is believed by a large number of producers that prices will be pretty generally maintained at government levels, as it is quite close to the cost of production, plus a reasonable profit.

Railroads are now buying a larger tonnage and that is stimulating production to a certain extent. Some of the larger consumers in industrial circles are running short of fuel and are buying in the open market. But generally speaking, reserve stocks are still large and little increase is looked for within the coming few weeks. The weakest feature is fine coal, which is a drug on the market. Prices on screenings and other small sizes are being cut to a greater extent than any other grade. Mine-run and prepared sizes are holding up fairly well.

The domestic trade is rather slow. Outside of the demand for the so-called fancy grades, such as Pocahontas, there is little domestic tonnage moving. Retail stocks are apparently sufficient for the present and there is no disposition to increase them. The unusually warm winter has caused heavy stocks to be accumulated by some retailers, some of which will have to be carried over. Reports show that consumers will also carry over a considerable amount, but not as much as was previously supposed.

CINCINNATI

Market remains quiet, but improvement in tone is noted. Some contracts are being signed, on a basis of present prices. There is little activity.

Coal men in the Cincinnati district report a slight improvement in the tone of the market lately, evidenced more by almost intangible indications of a change in feeling than by any specific change in demand or in prices. The work of reëstablishing the coals which move through this gateway on the markets where they were formerly distributed is getting slowly under way, hampered, naturally, by the extreme quiet of the market and the negligible demand noted in all quarters. It is taken for granted, however, that as time goes on this process will be hastened, to a point where the normal channels of distribution will again be established, and a volume depending on conditions will be distributed regularly.

Locally demand remains as it has been for some weeks past, quiet in all departments of the market, and it bids fair to remain so indefinitely, in the absence of some factor to improve it which is not now in sight. The weather seems definitely to have settled into spring, as generally expected, and prospects of further cold weather, necessitating fuel consumption for heating purposes, are getting more and more remote.

Interest in contracts for the year is confined largely to dealers and their agents, as consumers naturally feel that the situation is in their hands. However, large industrial concerns, whose consumption of coal is a fixed quantity, realize that it might prove dangerous, as well as bad business, to neglect arranging for their supply of coal, and are accordingly entering into contracts with their coal connections for their regular supply.

LOUISVILLE

Operators and Jobbers reporting slightly better demand for steam coal, with domestic demand about the same. Production said to be slightly larger. Producers disturbed over labor situation, and refusing long-term contracts.

The coal trade reports a slight improvement in steam demand, and is generally of the belief that things will open up somewhat about Apr. 1. It is claimed that the mines are doing slightly better than they were, production being around 50 per cent. for the fields. There is a fair demand for domestic coal, with dealers buying close for immediate use, and no large stocks in this market. A good deal of coal is on board cars at mines awaiting orders for shipment.

Prices are ruling rather firmly on domestic, but run-of-mine and nut and slack are slightly weaker in the eastern Kentucky fields. Western Kentucky operators are holding firmly to their old prices, claiming that it is impossible to produce coal profitably under existing conditions for less money than the Fuel Administration figures. Some western Kentucky operators claim that they will close down rather than cut prices, as they have operated many years on a very meager profit, and sometimes have met with direct losses. The war is said to have saved many of them from bankruptcy, in their efforts to compete with higher grade coals on a lower price basis, due to the cost of production being about the same for both grades.

Mine quotations, on short ton basis, not including brokerage of 15c. a ton are:

	Eastern Kentucky	Western Kentucky
Block and egg	$2.85 to $3.00	$2.60
Run-of-mine	2.20 to 2.40	2.35
Nut and slack	1.85 to 2.00	2.05

These are basic prices, there being some mines getting more and some less. It is reported that some eastern Kentucky nut and slack has sold as low as $1.75 per ton, and some western Kentucky at $1.85. Some eastern Kentucky mines are getting $2.40 @2.50 for run-of-mine; and $2@2.10 for nut and slack.

The strength of the market was shown when the Louisville Railway Co. asked for prices on a year's contract, calling for eight to ten cars a day, and an annual tonnage of between 85,000 and 90,000 tons. The company was somewhat surprised at being quoted $2.05 on western Kentucky nut and slack, this being the lowest bid, as operators were afraid of long contracts, and the western Kentucky operator making the bid was doing so on a full price basis.

BIRMINGHAM

Market conditions fail to show improvement during the past week. Steam business weak, while domestic demand is holding up well. The dull steam trade curtails the supply of domestic sizes.

The inquiry and bookings for steam coal in this field is confined mostly to small tonnages to meet current requirements of consumers. The Southern Ry., which for some time has been only taking minimum deliveries on contracts in this district placed orders for an additional tonnage aggregating probably 50,000 tons, the business being prorated among the contract mines, and to some operations where no contracts were held. Other lines are only taking the minimum allowed in contracts. Steam quotations are as follows per net ton mines:

	Mine-Run	Prepared	Slack and Screenings
Big seam	$2.45	$2.75	$2.40
Black Creek and Cahaba	3.45	3.75	3.05
Corona Jagger-Pratt	2.85	3.05	2.45

There is need for more domestic coal than is now being obtained in this district, the output being seriously affected by the slump in the steam market; and while there is a feeling that a good demand will obtain for domestic grades right along, the supply will not be in line with the requirements until there is a very perceptible improvement in the steam trade. The usual Apr. 1 prices have not been announced, and little if any contract business has been offered, though inquiries are beginning to come in. Current quotations are about as follows per net ton mines:

	Lump and Nut
Black Creek and Cahaba	$3.85@4.50
Big Seam	2.90
Corona	3.40
Carbon Hill	3.15
Climax and Montvallo	5.00

Mining operations are on a much restricted basis, commercial mines running from two to five days per week.

Coke

CONNELLSVILLE

Softening in market continues. Operators do not have to run. Range in foundry coke.

Cost of production has now become a real factor in the coke market, the almost continually declining prices of the past two months having brought the market down to about the cost level for the higher priced operations. Counting everything, including overhead, and charging the coal at something like market value, there are many operations that will show more than $4 as cost, and that is a price at which coke is readily obtainable. Some operators have lower costs other than others and some are

willing to forego their overhead, as most of it would count if the mine were idle.

Some operators, having made large profits in the past two or three years, are disposed simply to stay out of the market except as they have contract coke to deliver and are not attempting to make the slight profit they might possibly secure by making additional sales. In this respect the industry is in better shape than ever before, as in past years some operators have had to operate, profits or no profits, merely to keep their money turning and to encourage the banks to which they owed money. All this is changed now, the operators being able to do as they please.

Furnace coke is freely offered, though not in very large lots, at $4, for prompt or delivery over a fortnight or month. There are some offerings at less, but most if not all of them could not be classified as standard grade. So much 72-hour coke is being made, with the short running time now so common, that there is plenty of foundry coke and 72-hour coke, of a grade that can be had at but little above the price for furnace. Fair grades, however, would command fully $4.50 and better grades $4.75 or $5, while two or three of the old line producers of well known brands, having contracts in force at $6, will not shade that figure at all, and of course they make few if any sales. The market is thus quotable at $4 for furnace and at $4.50@6 for foundry, per net ton at ovens.

Middle Western

GENERAL REVIEW

Market conditions healthier and optimism reigns. Prices holding up above former Government maximums. Small demand for steam coals.

During the past few days the market has developed a much healthier tone. This has been brought about, not so much by an actual increase in sales, but by recent developments in the stock market in New York and Chicago. All good industrial shares are in an upward movement, and it is generally thought that those in a position to know believe better times are in store for the country in the immediate future. At all events, it is a fact that the bigger operators and jobbers are looking forward with more optimism than heretofore.

Until very recently the operators in Franklin and Williamson Counties, of Illinois, and the Fourth Vein district of Indiana, have not made any contract prices. These gentlemen felt that conditions were too unsettled to justify the making of a price on their coal to cover a year's shipments. Now that the coal industry has had a chance to adjust itself, the operators feel safe in quoting contract prices.

Given below are the figures for Franklin and Williamson Counties. Opposite them are the prices set on these coals by the Government, which prices were canceled by the Fuel Administration effective Feb. 1:

	Contract Price F.o.b. Mines, per Ton	Former Government Price per Ton
6x6-in. furnace	$2.75	$2.55
6 in. lump	2.75	2.55
3x2-in. small egg	2.75	2.55
2x1¼-in. stove	2.75	2.55
1¼x⅞-in. chestnut	2.65	2.55
⅝x⅜-in. pea	2.55	2.55
Mine-run	2.45	2.35
2-in. screenings	2.20	2.05
1¼-in. screenings	2.10	2.05
⅝-in. screenings	2.00	2.05
No. 5 or ½-in. screenings	1.85	2.05

The contract prices for the Fourth Vein district of Indiana are as follows:

4-in. lump	$2.75	$2.55
2½-in. lump	2.70	2.55
4x2½-in. egg	2.70	2.55
4x1¼-in. railroad egg	2.65	2.55
2x1¼-in. nut	2.65	2.55
1¼-in. lump	2.65	2.55
Mine-run	2.45	2.35
2-in. screenings	2.25	2.05
1¼-in. screenings	2.15	2.05

A glance at the foregoing figures will show conclusively that the operators do not propose to run their mines and deplete their properties at a loss. It also shows the operator—that is, the larger and more substantial ones—have confidence in the future.

Actual market conditions for the past week have been about as usual—that is, there has been but little demand for steam coals. What steam coal is moving is, nine times out of ten, sold at the full price. The domestic situation today is unusual, inasmuch as most of the large mines producing good coal are from one to two weeks behind on practically all sizes of their domestic products. As a result, and in order to get full running time, as well as keep cheap coal off the market, steam sizes are being stored until the time will come for a strong steam coal demand.

CHICAGO

Domestic coal in good demand, though steam coal market is inactive.

The domestic trade in Chicago is fairly active, with good coals in demand. This is due entirely to the cold snaps this city has been enjoying for the past week. The weather man also promises a few more weeks of winter before spring arrives. The steam coal market, as usual, continues inactive, and not much change is to be looked for during the next few weeks. Operators and jobbers report shipments cut down rather than increased.

There is a sharp demand in Chicago for good coal salesmen. A great many companies let their sales organizations go to pieces during the last few years, when coal was scarce, and as a result, now that a good sales force is of the utmost importance, these operators and jobbers are doing their best to rebuild their organizations.

MILWAUKEE

Market continues dull and lethargic. Holders of coal doing everything possible to reduce stocks.

The coal market continues in a lethargic state, with mild, spring-like weather operating to check consumption. Dealers are bending every energy to reduce stocks, which are heavy for the season, as there is bound to be a loss in holdover bituminous at least. All agree that there will be no material changes in prices until May; as to what will come then nobody will venture to prophecy. Some hard coal continues to come by rail; also small consignments of screened Pocahontas. Shipments to the interior continue light.

Following are the coal prices at Milwaukee, per short ton, effective Mar. 1. The prices given include delivery. At the yards the prices are 50c. per ton less:

	Domestic Short Ton
Anthracite—	
Egg	$12.20
Stove	12.40
Nut	12.50
Pea	11.00
Buckwheat	10.60
Bituminous—	
Pocahontas mine-run	$8.15
Hocking, screened	7.90
Youghiogheny, screened	7.90
Pittsburgh, No. 8, screened	7.90
West Virginia, screened	8.40
Splint, screened	8.40
Kentucky, screened	8.40
Illinois, screened	7.25
Coke—	
Solvay, large sizes	$11.50
Solvay, small sizes	10.25
Smithing	8.40
Steam—	
Youghiogheny, Hocking and Pittsburgh No. 8, screened	$7.18
No. 8, pile run	6.93
No. 8 screenings	6.68
West Virginia, Kentucky and splint Screened	7.68
Pile run	7.43
Screenings	7.18
Illinois and Indiana, screened	6.50
Pile run	6.25
Screenings	6.00
Smithing	7.68

ST. LOUIS

A continued quiet and easy market, with no demand of any kind. Steam and domestic business falling off. Surplus of all kinds of coal, with nothing promising to look forward to.

The local condition still continue to be a problem. The steam demand seems to be falling off instead of picking up, with the result that the market is glutted with steam sizes. There is nothing to indicate at this time that these conditions will improve. If anything, it is likely to grow worse. This not only applies to St. Louis proper, but it is general throughout this section.

The mild weather continues and there is little demand for domestic coal of any kind. Such orders as are being taken are usually for small lots. Then, too, it is usually for the cheaper grades of coal. A careful survey of the country districts reveals the fact that former users of coal have found it much more economical to use wood, which has been exceedingly plentiful the last couple of months on account of the oversupply of labor. The mild weather gives the farmer a chance to get the wood cut and hauled in without much trouble.

The local demand for anthracite is extremely easy and there is practically no demand for smokeless, with no Arkansas coming in. The local supply of coke continues to pile up, with very litle movement and no prospects of much for the future.

There is no change in the retail market, and the prevailing circular per net ton f.o.b. mines is:

	Mt. Olive and Staunton	Standard
Franklin County		
Prepared sizes, lump, egg, Nos. 1 and 2 nut	$2.75	....
Williamson County		
Prepared sizes, lump, egg, nut	$2.55	$2.55 $1.90@2.25
Mine-run	2.20	2.20 1.60@1.70
Screenings	2.05	2.05 .95@1.10
3-in. lump	....	2.30 .....
2-in. lump	....	.... 1.75@1.90

Williamson-Franklin rate to St. Louis is $1.10; other rates 92½c.

COAL AGE

Volume 15 New York, March 27, 1919 Number 13

Removing the Causes of Trouble

By Floyd W. Parsons

LABOR unrest is not a new disease; it is as old as humanity. But the present epidemic is more virulent and more widespread than ever before, and the pity of it is that back of all the trouble are real causes. If certain capitalists and industrial leaders had not exploited labor in the past, there would be no such upheavals as occur today,

It is human nature to condemn a whole class because several members are unjust. A dozen dishonest employers can throw an industry into bad repute. The same truth applies to labor organizations. The wonder is that in the light of this common fact real citizens should fail to expel from their councils and associations those who perpetrate wrongs and foster discontent. Whether the man be employer or employee, there should be no place in the business community for him if his life holds no thought of the full responsibility he owes his fellow citizens.

Health is the precursor of happiness. It is often the index of a man's worth to his company. Individual efficiency is determined by endurance of body and clearness of mind. An emergency often arises and prompt action is necessary. Sickness and indecision are twin brothers.

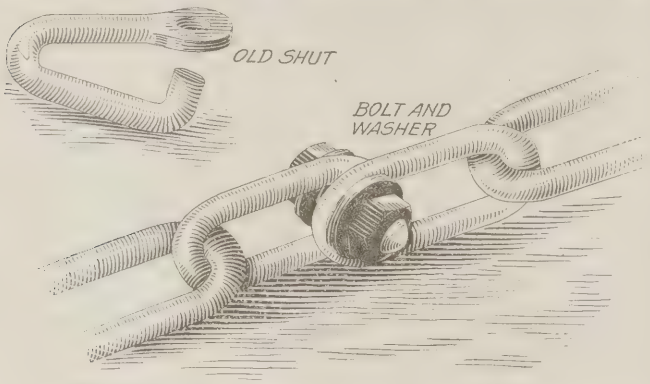
There are several great corporations in America that through all the turmoil of recent years have never had a strike. The managements recognize that labor unrest is due, not only to wages and hours of work, but to unwholesome habits of life that are encouraged by dull, shabby, unsanitary homes. Investigation has proved that the labor turnover at a plant can be more than cut in half by providing the employees with decent houses, good drinking water, proper facilities for washing, gardens, hospitals, healthy and sufficient milk supplies, schools, rest and recreation centers, relief, compensation and insurance funds and properly supervised commissaries.

Nothing that has to do with the operation of a mine is more important or more worthy of careful study than human fatigue. The development of energy in the body is almost identical with the development of steam in a boiler. In order that a workman may have a normal amount of muscular energy, he must be fed plenty of fuel, have sufficient oxygen with which to burn it and possess a system with ability to carry off the ashes or waste. When one of these functions fails to operate efficiently, the result is body fatigue.

Hardly a company but has on its pay-roll dozens of worthy workmen who are deficient in energy because of conditions that might be removed. Employees, and especially housewives, should be taught the value of a mixed diet of food. They should be educated to know how to fill a lunch box and what to put in it. Much benefit comes from providing clean places for the men to congregate, rest and eat.

In every effort to remove fatigue the manager's plans have to include a carefully prepared discussion of personal hygiene that must be got across to the employee. Not much can be accomplished unless there is care of the individual by himself. The workman should be made to feel the importance of regular meals, thorough mastication, hours of rest and sleep, ventilation of rooms, regularity of movements from the bowels, the cultivation of cheerfulness, and above all the necessity of keeping a clean nose and mouth. The time is coming when no man, capitalist or laborer, will eat a meal without first washing his teeth and hands.

More than 50 different varieties of disease-producing microorganisms have been found to inhabit the mouth. When these bacteria are swallowed with food, they cause fermentation in the stomach, and then passing into the intestines produce poisons that are absorbed and create body fatigue. At the same time they lower the individual's resistance to disease. As to hands, it has been found that although there is no known method of perfect disinfection of the hand, culture tests prove that the number of germs remaining on the hands after washing is very much less when the man uses a brush and afterward rubs with a rough, sterile towel, than when only soap and water are used. Paper towels are a menace in that they do not remove the bacteria.



The foregoing thoughts are not written with any idea of even covering a part of the problem of health in its relation to industry, but are presented for the sole purpose of arousing the employer's interest in a subject that is vital to the solution of present-day troubles. This is no time to strike the flag without firing a shot, and the best kind of shots to fire are those that are aimed to root up and destroy the things that breed discontent and create class hatred.

IDEAS AND SUGGESTIONS

Temporary Chain Repairs

BY CHARLES H. WILLEY
Concord, N. H.

Often there is need to quickly make temporary repairs to a parted chain or to join two bights of chain together. It has several times come to my notice that

DETAILS OF TWO MAKESHIFT CHAIN REPAIRS

many men try tying the chain, if it is a small one, or binding the two ends with wire. Having used the two makeshift repairs here shown with much satisfaction, I am passing them along to others.

Surveying Without an Instrument

BY T. EDWIN SMITH
Coalhurst, Alberta, Canada

It is often necessary to make a survey when a transit is not available or convenient, and in case any reader of *Coal Age* should find himself in that predicament the following hints may prove useful.

I once had occasion to survey a coal mine and connect the underground survey with the surface survey when my only apparatus was a new steel tape. A section line ran near the mine and two stakes on this, one a quarter of a mile and the other a mile and a quarter away, enabled me to extend the line and mark it as was necessary.

I selected a point on this line, extended, that would be convenient to the top of the slope and drove a stake marking the station. On this line and back toward the flags at the section corner I measured a distance of 20 ft. and marked it with a pin. I sighted then toward the mine and on the line, and 20 ft. away located another point and marked it with a pin. The last part of the work at this point was to measure the distance between the two pins. In this case it was 25 ft. 6 in.

I now had a triangle located on the ground with one vertex at the station of the survey and two sides coinciding with two courses of the survey. Now knowing the bearing of one line, I had only to solve for one angle of the triangle whose sides were given in order to compute the bearing of the other course.

There are two ways of computing this angle. First, call the angle included between the two lines A and the side opposite that angle a, then

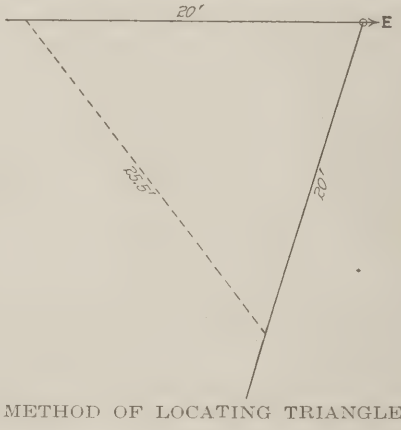
$$Cos\ A = \frac{b^2 + c^2 - a^2}{2bc}$$

It does not matter which side we call b. This formula will give two results for one of the other angles, but as we are concerned only with one this does not matter. From the data given

$$a = 25.5 \text{ ft.}$$
$$b = 20 \text{ ft.}$$
$$c = 20 \text{ ft.}$$

$$Cos\ A = \frac{400 + 400 - 650.25}{800} = \frac{149.75}{800}$$
$$= 0.18719 \text{ and } A = 79^\circ\ 13'.$$

This gives the angle, and the course run will have the bearing S 10° 47′ W.



When two legs of the triangle are the same length the angle may be computed as follows:

$$Sin\ \tfrac{1}{2} A = \frac{\frac{1}{2} a}{c}$$

In this case it works out:

$$Sin\ \tfrac{1}{2} A = \frac{12.75}{20} = 0.6375$$
$$\tfrac{1}{2}A = 39^\circ\ 36'\ 30''$$
$$A = 79^\circ\ 13'$$

At this mine the coal was hauled up a slope and it was necessary to calculate the rise in order that the thickness of cover over the coal might be placed on the map. The pitch distance was carefully measured, then

METHOD OF LOCATING TRIANGLE

the horizontal distance was measured by breaking chain, a carpenter's level being used to keep the tape level and a sharp pointed plumb bob allowed to drop two or three inches, marking the horizontal steps. The slope was 190 ft. 3 in. long while the horizontal distance was 170 ft. 5 in.

The table on pages 4 and 5 of the "Coal Miners' Pocket Book" enables the odd inches and fractions to be reduced to decimals of a foot without trouble.

From trigonometry, the cosine of the angle of inclination is equal to the horizontal distance divided by the pitch distance.

$$Cos\ angle\ of\ inclination = \frac{170.4167}{190.25}$$

The angle of inclination is therefore 26° 31′ 30″.

The rise of the slope is equal to the pitch distance

times the sine of the angle of inclination. In this case it was 84.85 ft. or, say, 85 feet.

Inside the mine I found a situation somewhat more involved. A narrow slant turned off the entry at such an angle that long measurements were impossible. The timbers and the coal rib made it impossible to lay off definite distances in each direction and then measure the third side. Having marked the intersection of the center lines of the two places, I sighted down the entry toward a light placed at the face and located to points on two ties several feet away. I drove small nails in these ties and connected them with a cord. Next I sighted toward a lamp at the face of the slant and in a tie drove a small nail at a distance of 9 ft. 9¼ in. from the corner. From this mark the tape was stretched to the entry between timbers and as near as possible to the corner of the coal and its intersection with the cord stretched previously in the entry noted. The distance up the entry was measured and the cross measurement taken. This provided all the data necessary for computing the angle. The three sides were respectively:

$a = 9'\ 9\frac{1}{4}''$ or 9.77 ft.
$b = 8'\ 6''$ or 8.5 ft.
$c = 8'\ 1\frac{1}{2}''$ or 8.125 ft.

The angle made by the crosscut with the entry was thus found by computation to be 52° 20′.

This method can be used not only when a transit is not available, but is useful during a high wind; for a steel tape stretched close to the ground is but slightly affected by a wind that would render observations taken with a transit unreliable.

The accuracy of the results will depend upon the care taken in sighting the lines and measuring distances. In general the results are as close as those obtained from ordinary mine surveys made with a transit.

THE many suggestions, mining kinks and wrinkles published in the Ideas and Suggestions Department of COAL AGE are of great practical value to all readers actually engaged in operating mines. From the 10,000 and more men the paper reaches each week there should come a much larger number of such ideas. There are clever arrangements of a simple and practical nature in use at all mines. What may be an old story to one is likely to be just the idea some other fellow is looking for. We particularly invite all COAL AGE readers to send us ideas and suggestions suitable for this department. Everything published is paid for at a liberal rate.

Mica Insulated Armature Coils for Use on Alternating-Current Generators

Failure of armature coil insulation is the most common single cause for generator shutdowns. These are invariably expensive, either through loss of revenue or repair charges, or both. A perfect insulation—one that never fails—is unknown, at least at present. Mica is probably the best available material for insulating purposes.

The Westinghouse company and other manufacturers are now finding mica a solution for some of the problems of the large-capacity, high-voltage and high-speed designs of electrical machines demanded by the up-to-date power plant.

Mica is a first-class dielectric. Its insulation resistance increases with temperature—a valuable characteristic for higher temperature work, and in direct contrast with the properties of treated tapes, in which the insulation resistance and loss increases rapidly at temperatures above 100 deg. It is unaffected by temperatures far in excess of those encountered in the modern, well-ventilated alternator. It is impervious to the static discharges present in all high-voltage machines. It is resilient and retains its resiliency indefinitely—thus helping to hold the coil tight in its slot. Mica is a mineral obtained in the form of large crystals. These split readily into thin, parallel-sided laminæ, or flakes. The flakes are pasted uniformly on cloth or paper to facilitate handling and to provide a mechanical support during application.

In the form of a "wrapper"—that is, pasted on large sheets of specially treated paper—mica is used on all modern alternating-current generators on the straight sides of each armature coil, to provide insulation between conductor and iron, the operating voltage of the machine determining the number of turns, or the thickness of this insulation wall. All known insulating materials are relatively poor heat conductors. This is equally true of mica and treated tapes. Therefore the tighter and the thinner the wall, the better are the heat radiating characteristics of the coil. For the lower-voltage machines the mica wrapper is applied as tightly as possible by hand. For the higher-voltage windings (in general 6600 and above), where the insulation wall must be relatively thick, special machines apply the wrapper under heat and pressure, and finish it to a solid, compact wall.

Frozen Rope Causes Accidents

Manila or other fiber rope is made brittle by freezing, and should be thawed before being used. Accidents happen when this precaution is neglected.

Few contractors take proper care of fiber rope; a neglect of handy rope and of rope used for tackle is an extremely flagrant waste of material. Fall rope and those used in standing rigging do not absorb much moisture, soon dry out in the wind, and are comparatively free from dirt. No special care need be taken to prevent them from freezing. With general utility rope the case is different. A manila rope contains only a small amount of natural moisture, but it will absorb as much as 30 to 40 per cent. in a damp atmosphere.

The moisture does no harm, but the freezing of the contained water makes the fibers brittle and the rope weak; therefore the frost should be thawed out before the rope is used for heavy lifts or pulls.

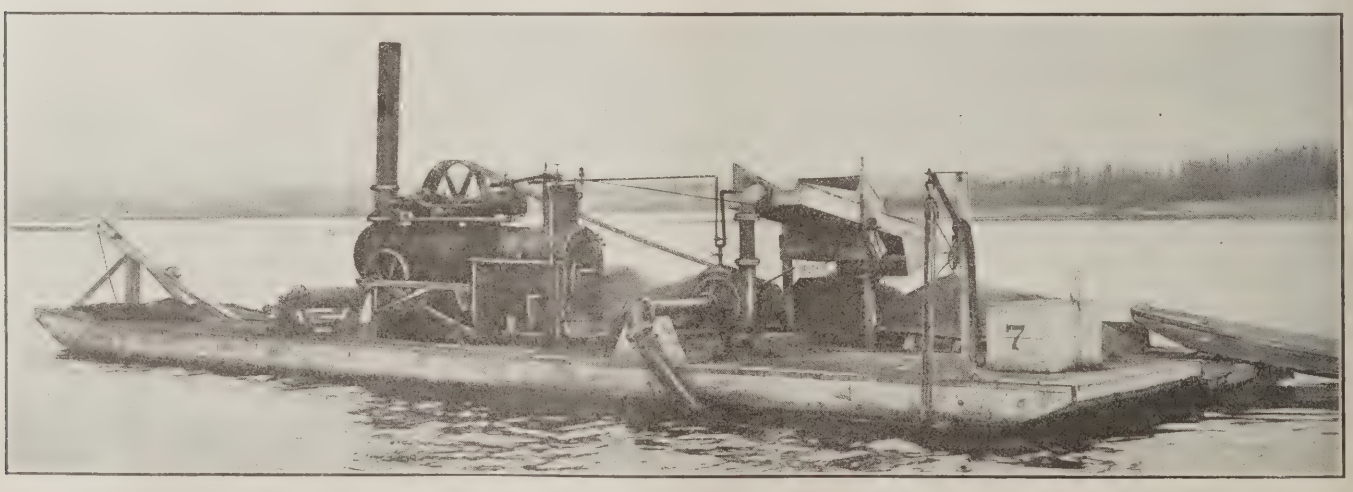
Dirt is chiefly objectionable because it reduces the working life of rope. When working, the rope fibers move on each other and the grit in the dirt cuts and frays them rapidly. On a construction job a visitor recently had to pick his way over the tangle of handy rope and tackle left lying where last used, and frost was in every inch of this rope.

When finished with a rope it should be put where it will not freeze or be ground into the mud; if this is impracticable, coil the rope and set this coil on a pile of boards or on any other handy platform so that it will have some chance to dry.—*Engineering News-Record.*

Handling River Coal at Harrisburg

By Henry J. Edsall
Philadelphia, Penn.

THE dredging of small anthracite coal from the rivers that flow through the anthracite coal region of Pennsylvania, or that have branches in this region, has come to be quite an industry. Along the Susquehanna, in the Harrisburg region alone, the amount of coal taken out of the river each year probably exceeds 200,000 tons.



This coal is washed down the river in times of high water, especially in the spring. It settles to the bottom in the quieter stretches where there is comparatively little current. There is a tendency for the coal to collect in certain spots, due to depressions in the river bottom, eddies and other causes. This coal forms into beds, some of which are quite large. The usual method of dredging the coal in the Harrisburg region is to suck it up with a rotary dredge pump. This has a 6-in. suction pipe with a bonnet on the lower end about 18 in. wide and an intake opening through which the coal is sucked as the bonnet moves along the river bottom. The dredge pump is set up on a flatboat, which is operated by means of a horizontal boiler and engine. In the bow of this boat is a small-diameter drum, 3 or 4 ft. long, on which an anchor rope can be wound.

When a bed of coal is located the dredge boat is taken to the upper end of the bed, the anchor thrown overboard, and then the dredge drops downstream until the anchor rope is paid out. The pump is then started and the suction end lowered into position so that the dredging operation may begin. At the same time the drum at the bow begins to slowly wind up the anchor rope, power being obtained for this purpose by an auxiliary drive from the engine. The dredge thus moves forward slowly until the anchor rope is wound up or until the bed of coal is passed over.

SUCTION NOZZLE OF THE DREDGE

The dredge pump discharges the coal and water to a screen about 6 ft. long through which the water washes the mud and fine coal. The good coal goes

CLOSE UP VIEW OF THE SUCTION DREDGE WITH A FLATBOAT ALONGSIDE

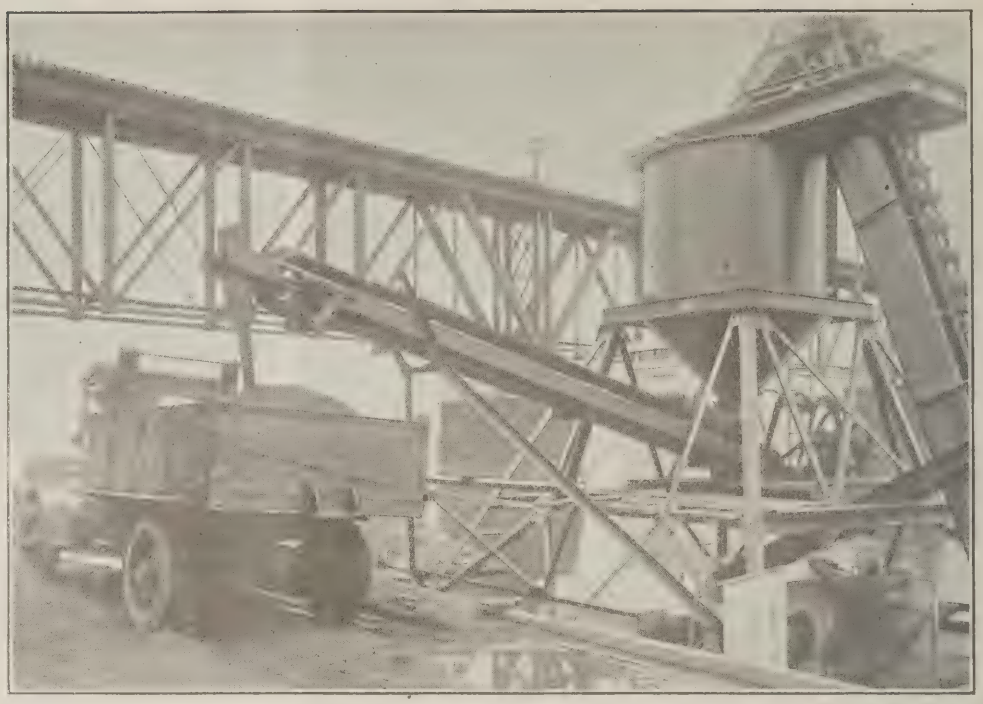
VIEWS OF THE MACHINERY INSTALLATIONS AT OPPOSITE ENDS OF THE DREDGE

over the screen to a flatboat tied alongside the dredge and is helped over the end of the screen by an attendant with a hoe. This attendant allows more or less coal to remain at the lower end of the screen to act as a dam to keep any water from washing over the end instead of going through the screen.

The flatboats for transporting the coal are about 50 ft. long by 10 ft. wide, and are decked over. The coal is piled on the flat deck, which is provided with 12-in. planks set on edge along each side to keep the coal from spilling over. These boats will carry from 15 to 20 tons each. For moving the flatboats there are steamers of about the same size as the coal boats but equipped with paddle wheels at the stern. The paddle wheels are driven from a horizontal combination engine and boiler by means of a belt drive to a countershaft, thence through a chain drive from the countershaft to the paddle-wheel shaft. One of these steamers will handle several loaded coal boats at a time, and they look quite picturesque with their paddle wheels churning up the water at the stern and the flatboats in front and possibly alongside.

The unloading of the coal from the boats with a minimum amount of labor is somewhat of a problem, since each boatload is a comparatively small amount; also on account of the coal being spread over a considerable area compared to the depth of the pile. To eliminate labor, a mechanical loader must go over the whole area of the deck and clean up all the coal; otherwise handwork is necessary. The unloading arrangement shown in the accompanying illustrations has accomplished this result almost perfectly, as it covers practically the whole area of the deck and leaves only a thin layer of coal that can be easily cleaned up by one man. This equipment will handle the coal at a rate of over 60 tons per hour, so that a boat can be unloaded in about 15 min. The power required to operate it is a small item of expense, the motors being of 7½ and 3 hp. respectively.

FOOT OF THE UNLOADING CONVEYOR



This arrangement includes three separate parts—the elevating element, consisting of a chain and bucket elevator with a spiral feeder at the lower end, a belt conveyor to deliver to the trucks and a 10-ton steel tank to act as an equalizing reservoir between the elevator and the belt conveyor. The machinery and the tank are supported on steel framework resting on two flatboats far enough apart to allow the coal boats to pass between them. This method of support was adopted largely because the most convenient point for unloading the coal at Harrisburg is in the park along the river front, where it is out of the question to consider building anything of a permanent nature either in the river or on the shore. This scheme, however, has other advantages since it keeps the structure symmetrical, with the elevator and bin in the center and as low as possible. Furthermore, the complete equipment can be removed and laid up for the winter to avoid damage by floods and ice.

It will be noticed that the elevator is pivoted at the upper end. This allows the foot to be swung forward, which also raises it, thereby providing for different levels of the boats with varying loads and also making it possible to get the loader into position and out of the way without interference.

The elevator is about 26 ft. long center to center of head and foot wheels and is of the single-strand centrifugal-discharge type. The standard malleable iron buckets are 12 in. long and 6 in. wide, and are attached to every link of the No. 710 malleable iron chain. Since the elevator operates on an incline, it was considered advisable to attach flatirons across the backs of the buckets and let these slide up and down in angle-iron guides in order to support the buckets on both the up and down runs and keep them from sagging or sway-

ing. There is also a steel casing around the return run to avoid danger and to catch any coal that spills from the ascending buckets or from the discharge at the head. The elevator foot shaft is extended at both sides for the spiral feeding device, which consists of a spiral ribbon 32 in. in outside diameter and with 12 in. pitch, the blades being made of $\frac{3}{4}$ x 3-in. steel flats.

A steel trough is provided at the back of the ribbon and this extends part way underneath. The coal thus cannot get out at the back; neither is there danger of injuring the man at the rear of the elevator through coming into contact with the ribbon. The ribbon is made right and left hand so that the coal from both sides of the elevator is pushed in toward the buckets, which are well filled if the foot of the elevator is kept against the coal properly. The coal is almost entirely cleaned up from the decks of the boats, the small amount left being easily shoveled up by one man and fed to the elevator.

TOWER, HOPPER AND CONVEYOR OF THE UNLOADING MACHINE

The elevator discharges at the head in the usual manner, over a chute into the 10-ton circular steel tank. This tank is 8 ft. in diameter and is made of $\frac{3}{16}$-in. steel plate properly braced and stiffened by angles and channels. The bottom is hoppered and fitted with a gate for delivery to the belt conveyor. Across the top of the tank beams are placed to support the head of the elevator. The frames that support the tank and machinery have two legs resting on each flatboat, the load being distributed on the deck of the boat by means of channels running part way across. The possible rocking of the boat is taken care of by a pin connection, which insures flexibility. The belt conveyor which runs from the tank to the trucks is 24 ft. long center to center of head and foot wheels and has an 18-in. five-ply rubber belt. This belt runs over standard troughing idlers on the carrying run and returns over standard return idlers. It is supported by means of a steel boom with a strut underneath which allows of adjustment in height of the boom. The belt conveyor has a somewhat larger capacity than the elevator, so that a truck can be loaded quickly, this extra capacity being also needed by the belt conveyor on account of its intermittent operation, which means that it has to handle the same amount of coal as the elevator, but in less time. The elevator operates continuously until the boat is unloaded, whether a truck is being filled or not. The bin, however, sometimes becomes filled when the trucks are not taking coal away fast enough, and in this case the elevator has to be stopped until some of the coal is taken out of the bin. The 7½-hp. motor is located on the platform at the head of the elevator and is geared direct to a countershaft which also acts as a pivot shaft for the elevator. From this countershaft a

AFFORDS AN EXCELLENT GENERAL VIEW OF THE UNLOADING STATION

chain drive extends to the head shaft of the elevator. The 3-hp. motor is located on the platform at the foot of the belt conveyor and geared direct to the conveyor foot shaft. The starting boxes for the motors are in a small closet on the flatboat nearest the shore, the feed wires leading from an underground conduit to this closet. There is also a push button near the delivery end of the belt conveyor so that the truck driver can stop this belt when his truck is full.

New English Coal Field to Be Extensively Developed

North Nottinghamshire, known to lovers of beautiful scenery as "The Dukeries," will soon see the development of its large coal resources on a hitherto unattempted scale. Some of the deposits are being worked already, but the greater part of this immense coal field is as yet untouched.

Enough coal exists in the area mentioned to insure the prosperity of this portion of the county for the next 100 years. Most of it is comparatively easy of access. Indeed, there is no coal yet to be developed in any part of England that lies nearer the surface than that in this district, and the demand for it is practically unlimited. Being of a hard texture, it is particularly suitable for transportation, and hence it is not surprising to find that before the war 40 per cent. of the output of the Nottinghamshire pits was exported, notwithstanding the fact that, lying in the center of England, it is farther from the ports than any other coal-producing area.

The Germans were particularly willing buyers. They found this coal far better for their blast furnaces and locomotives than their own Silesian and Westphalian product, and, thanks to British shipping, which, while bearing away from us the sources of our wealth brought back German manufactures as return cargoes, they also found it cheaper. Its chief excellence consists in its comparative freedom from sulphur—an important consideration in the making of steel. As compared with 2½ per cent. of sulphur found in Welsh coal, the coal of North Nottinghamshire contains only ½ per cent.

The principal agency concerned in the sinking of new pits is the Bolsover Colliery Co., whose pit near Mansfield, known as Crown Farm, holds the world's record for output in a given time, 4850 tons having been brought to the surface in 7 hours 40 minutes[1]. The company also runs two other important pits at Bolsover and Cresswell, in Derbyshire. The Dukeries comprise, in the main, the estakes of the Duke of Portland, the Duke of Newcastle, Earl Manvers and Lord Savile.

The first of the new pits, at Blidworth, known as the Rufford Colliery, was completed just before the war by the Bolsover Colliery Co., and is now turning out some 2300 tons a day. This could easily be increased to 4000 if the necessary labor were available. Another pit on the Duke of Portland's estate at Clipstone, four miles from Mansfield, will be sunk by the same company as soon as the Government gives permission. All the surface work has been done, and sinking was about to commence when the Government commandeered the labor and material. Coal is expected to be reached here at a depth of 1860 feet.

The next collieries to be started will be at Blidworth, by the Newstead Colliery Co., which has acquired the mineral rights over an area of five or six thousand acres. Not far off is Ollerton, where the Butterley Coal and Iron Co. and the Stanton Iron Co. have jointly arranged to work the coal under Lord Savile's estate. Belonging to the same owner is Bilsthorpe, with an area of 6000 acres, where a borehole has been put down by the Stanton Iron Co. and the coal shown to be satisfactory. Rufford, to which allusion has already been made, possesses the thickest coal bed of any so far proved in this neighborhood.

Marked for later development are the coal deposits under Sir Charles Seely's Sherwood estate, including Oxton, which lies between Blidworth and Farnsfield. A company is to be formed to work the coal, and negotiations are also about to be opened with Earl Manvers to deal with that on the Thoseby estate, where there is satisfactory reason to suppose the deposit is good.

It is extremely probable that the Wigan Coal and Iron Co., which now has one colliery at Manton, will sink another on the Duke of Newcastle's estate near Worksop. About 20,000 acres are here available.

In nearly all the projects mentioned the leases have been actually let, but to sink and equip one of these collieries for an output of 4000 tons a day will cost from £650,000 to £750,000, without reckoning anything for railways and workmen's dwellings, before a single ton of coal is raised. At a moderate computation between four and five millions sterling will be invested in the exploitation of this new coal field. Each of these collieries will employ, on an average, 2700 men and boys, which will mean some 20,000 miners, or a new mining population of 100,000 souls.

Railway extensions are projected to deal with the resulting growth of trade and population. The Mansfield Ry., which owed its inception a few years ago to the advent of fresh collieries in the neighborhood, will be connected by a branch line with the Great Central Line from Chesterfield to Lincoln at Blidworth, where the new population is already being housed in a village laid out on town-planning lines. A hundred and seventy houses had been erected when the outbreak of war stopped building operations, but the complete design provides for 500 dwellings. Similar model villas will be laid out for the other collieries, since the coal seams are so numerous and of such a thickness that 40 years would be required to exhaust one of them. Below the upper hard coal lie other beds, some of which can certainly be worked at a profit. At the present rate of production this new coal field will not be exhausted for 150 or 200 years. Thousands of houses are already in contemplation and would have been erected ere this but for the war.

[1]The author of this article is evidently unfamiliar with such American operations as the Orient mine of southern Illinois, and Vesta No. 4, near California, Penn.—EDITOR.

IT HAS BEEN STATED by an authority conversant with pulverized-coal furnace practice that the life of a furnace burning powdered fuel is not as long as that of other forms of furnaces. It can also be stated that the life will be the same as that of other forms of furnaces operating under the same capacity rating. It is considered, however, that the expense of furnace renewal is more than offset by the advantages of using pulverized coal.

Agencies in the Transformation of the Connellsville Region

By John L. Gans
Connellsville, Penn.

THE change in the character of the Connellsville coke region, from a beehive coke manufacturing to a coal-producing center, is being effected through what may be termed four different agencies. In order of sequence by which they have become operative they are: The adaptation, whole or in part, of existing coking plants, both merchant and furnace-owned, to the shipment of byproduct coal; the acquisition and development by furnace and steel interests of Connellsville coking coal as a source of raw product for the manufacture of byproduct coke at the point of consumption; the association of coke producers who are owners of coking coal with steel interests in the joint ownership and operation of byproduct coking plants outside of the Connellsville region, and the establishment of relations between a steel producer, who is also a byproduct coke producer, and an independent Connellsville coal-land owner, whereby the latter becomes a producer of byproduct coal for the exclusive use of the former.

Tracts Being Developed for Byproduct Coal

The order of importance is perhaps different from that just given and is very likely to undergo changes as developments grow apace. At present, however, the shipment of raw coal from plants originally designed, and for a long time operated, as coking plants only, but now partially and in some instances wholly diverted to the new purpose, takes the lead in volume of tonnage. The development of tracts by new mines to be devoted solely to the production of coal for byproduct coking is yet in the primary stages, but it is fast assuming such proportions as will eventually make these operations very important, if not the most important, factors in the new order.

Several merchant producers of coke have been shippers of byproduct coal in varying quantities for a number of years past and within the last year have engaged somewhat more extensively in that line. Many of the more recently constructed plants were equipped for loading coal direct from the tipples into railroad cars, and others have made such provision, hence the number of coal-loading plants has gradually increased as the byproduct industry has expanded. The Republic Iron and Steel Co., operator of the Republic plant of 400 beehive ovens, has been shipping its excess coal to its byproduct plant for several years, together with the partial, and sometimes the whole, output of the Martin plant, which has an equipment of 244 beehive ovens. The Bowood mine of the same company is an exclusively coal-loading plant, as is also the Atchison mine since the permanent abandonment of its 120 beehive ovens.

All of these operations are in the Lower Connellsville district, from which virtually all of the byproduct coal is being shipped. Early last spring the 470 beehive ovens of the Brier Hill Coke Co. in the Lower Connellsville district were blown out, since which date the entire mine production has been going to the Brier Hill Steel Co.'s byproduct coking plant at Youngstown.

The LaBelle Coke Co., operating 200 ovens, has within the past two years completed a barge-loading plant and ships coal to the LaBelle Steel Co., Steubenville, Ohio, for byproduct uses, while continuing part of its beehive ovens in blast.

Since last midsummer the H. C. Frick Coke Co., a subsidiary of the United States Steel Corporation, and the largest coke producer of the Connellsville region, has been making increasingly larger shipments of coal from a number of its mines in the Lower Connellsville district to the Clairton byproduct plant of the Carnegie Steel Co. As additional units were made ready for firing at this plant, coal shipments have been increased through cutting down the number of beehive ovens in blast at the several mines and diverting the coal by an elaborate underground electric haulage system to barge-loading tipples on the Monongahela River. This shifting of the destination of mine output has progressed until four large beehive oven plants—Colonial No. 4, Edenborn, Lambert and Ronco, with a total of 1612 ovens—have been relegated to the inactive list, while the coking capacity of the Leckrone plant has been cut down from 516 to 110 ovens.

Many Mines Overhauled and Improved

Meantime the Ralph, Palmer and Gates mines in Fayette County and the Dilworth mine in Greene County, at which no coke has ever been produced although some were so designed, have been overhauled and extensively improved and their output is being sent to Clairton. The 100 ovens at the Bridgeport mine continue to be operated, but the mine capacity has been increased and the excess coal output is shipped by river. At the Maxwell mine some miles up the river barge-loading preparations are under way, this being another step in the comprehensive plan for the Frick company to change its mines which are tributary to the Monongahela River into producers of coal for the Clairton byproduct plant.

To date there has been but a single instance of an owner of Connellsville coking coal, and operator of beehive ovens in the region, joining with a steel producer as owner and operator of a byproduct coking plant. That is the union of the W. J. Rainey interests with the Alan Wood Iron and Steel Co. in the formation of the Rainey-Wood Coke Co., which has a plant of the Koppers type of ovens in course of construction at Swedeland, Penn. This plant is to be supplied with coal from the mines of the Rainey interests right in the heart of the Connellsville region, and long the source of supply for the beehive ovens on the property. (This enterprise was more particularly mentioned in *Coal Age* in the issue of Aug. 8, 1918.)

Several developments are in progress in the Greene County extension of the Lower Connellsville district which are to be producers of byproduct coal for the

exclusive use of the parent steel and furnace interests. At present the most notable and farthest advanced of these enterprises is that of the Buckeye Coal Co., a subsidiary of the Youngstown Sheet and Tube Co. The plant of this company, briefly described in *Coal Age*, issue of Feb. 6, is located at the new town of Nemacolin, and will have an ultimate capacity of 6000 tons of coal per day, all of which will go to the byproduct oven plants at Youngstown.

What is herein termed as the fourth of the series of agencies through which the Connellsville region's evolution is being brought about has thus far but a single example. This is found in the comparatively recent purchase by the Jamison Coal and Coke Co., one of the leading merchant coal and coke producers of the Greensburg-Connellsville district, of 575 acres of coking coal in the Perryopolis section of the Connellsville district, which will be devoted to the production of coal exclusively. The property, which is already under development through two slope openings, will have a capacity of 2000 tons per day. The entire output will go to the byproduct plant of the Bethlehem Steel Corporation at Sparrows Point, Md. The new operation adjoins the holdings of the Washington Run Coal and Coke Co., one of the leading merchant producers of the Connellsville region and a long-time shipper of byproduct coal.

Even with the multiplication in number and variety of means whereby the coal of the Connellsville region, once held sacred to the production of beehive coke, is being utilized in the manufacture of coke, no alarm is felt among coke producers over the transformation that is in progress. Firm in the faith that Connellsville coal is as essential to the production of high-grade byproduct coke as it has been in the manufacture of coke by the more primitive process, the operators are accepting, even welcoming, the situation as an assurance that the prosperity of the Connellsville region is by no means at an end. Instead, it is the belief that, having a market for its principal product in two forms, rather than one as formerly, they are infinitely better positioned than when they were subjected to the "flings of fortune" in the "prince and pauper" days.

Germans Use Driving Belts of Paper

Some particulars of the paper driving belts which are now being introduced into German workshops are given in the *Bulletin des Usines de Guerre*, a translation of which appears in the *Compressed Air Magazine*. The paper is cut into narrow bands, which are then spun. The belts are made by a weaving or braiding process.

Woven paper belts are of two kinds—paper fabric and paper thread belts, the former being the more frequently used. The fabric is first cut into bands 40 m. (131.12 ft.) long, which are subsequently made up according to the desired width and thickness. A core of strengthening material is interposed, either cotton or sheet metal, though more recently these cores have consisted of paper thread and metal wires interwoven. The core is surrounded with the paper strips and the whole sewn with strong thread. Belts so prepared are said to be very flexible and to wear satisfactorily. Woven paper belts have a tensile strength of from 100 to 125 kg. per centimeter of width (560 to 700 lb. per inch of width).

Even Ireland Has Coal News

The Province of Connaught in Ireland lies in the northwest of that island. One of the counties in Connaught—Roscommon—has in the northern corner, which is wedged in between the counties of Leitrim and Sligo, the village of Arigna, where are located producing coal mines. It is stated that this coal has been successfully used at the Sligo gas works, though the coal is said to be of anthracitic variety. The field is commonly known as the Leinster coal field, for the coal is mostly found in that county, though Arigna is the principal point of development and after it the coal field is occasionally named.

The Government of Great Britain and Ireland is endeavoring to ascertain the quality of the coal in the Tyrone field in Ulster, which field passes under Lough Neagh, a comparatively large lake forming a sort of common corner monument for Tyrone, Londonderry, Antrim, Down and Armagh Counties. About $75,000 is to be expended toward experimental borings. They will be made near Lough Neagh, for it is believed that sheet of water masks the most desirable portion of the field. Coalisland is the most important town in the field, and after it the Tyrone field is often named.

PLAIN ENOUGH

Written Expressly for Coal Age

By Berton Braley

THINK of this a moment, prophet sad and glum:
Here's a world that must be built anew,
Built with tools and products of the shops that hum—
Has that little fact occurred to you?
Some one has to do it; who can do it best,
Europe, lacking labor and supplies,
Or this mighty nation with its wealth unguessed?
There's an answer plain before your eyes!

WE don't gloat at Europe in her misery,
Neither do we hold our losses light;
Yet the truth's before us, who can help but see
Logic of the facts that are in sight.
Men must live and labor; we have goods they need,
Products of our industry and brains,
Trade is therefore certain, as who runs may read,
Certain as the sunshine or the rains.

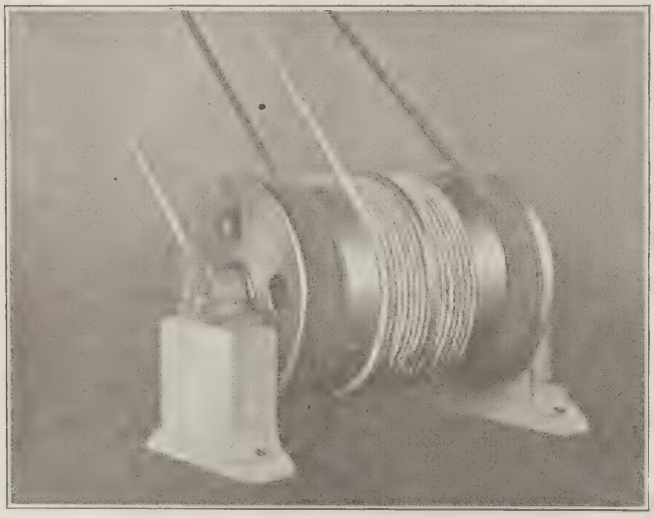
THINK of this a moment, blue and fearful soul,
Prophet of disaster far and near:
Trade means busy workshops, shops mean streams of coal,
Keep your courage up and never fear.
Chuck your dour statistics, take a broader view,
Men must have the fruitage of our skill.
There's a world that's waiting to be made anew,
We can help to do it—and we will!

Increasing Cage Safety

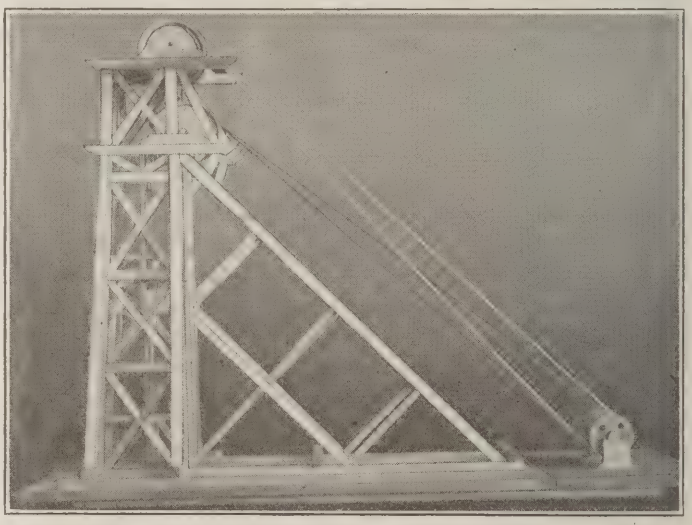
By Thomas Price
Nanaimo, B. C.

SYNOPSIS—*A disastrous accident resulted from a breakage of the hoisting cable and a failure of the safety catches on the cage to function properly. Extensive tests showed that these catches were at best unsatisfactory. A scheme for attaching two ropes to each cage, either one of which shall be capable of sustaining the load, was then devised. This is to be tried soon.*

IN SEPTEMBER of last year a serious accident occurred at the Protection Mine of the Canadian Western Fuel Co., Ltd., due to the breaking of the descending hoisting rope. This resulted in the death of 16 men. The accident occurred in spite of the fact that the cages were equipped with a type of safety catch that was considered a good one. At the time of the catastrophe the reason of the failure of these catches to work properly could at all not be accounted for. This led to a series of thorough and practical tests of the catches. For this purpose a trestle 45 ft. high was used, and guides similar to those employed in the shaft were bolted in position and the experimental cage fitted with the safety catches. Prominent mining men were present to see the tests carried out.



Several trials with the ascending cage were made, and in some cases the safety catches did their work but failed with the descending cage, which crashed to the ground every time. A new grip was tried. This certainly acted, but those present were of the unanimous opinion that while the catches stopped the cage they were totally unsuitable, the action being altogether too sudden and dangerous. This was conclusive evidence that something entirely different would have to be devised and proved the fact that any type of safety catch was more or less unreliable.



After much scheming the idea of using two ropes on each cage presented itself. This at first sight made it appear that great alterations would have to be made to the present machinery, or at least that extra winding drums would have to be added to those already in place. This would prove a costly change.

Thomas Price, master mechanic of the Canadian Western Fuel Co., Ltd., finally solved the difficulty by crossing the ropes from the drum to the two extra sheave wheels, which are placed above the present ones. Thus as one rope winds on to the drum, the other is wound off. The angle of the sheaves is adjusted to suit the center of travel of the opposite half of the drum. The ropes from the drum to the sheaves cannot possibly come together, being kept apart by reason of one rope being wound under the drum and the other over.

The size of winding rope used is 1½ in. in diameter. This could either be doubled on each cage or a smaller sized rope used, which would still increase the factor of safety. Of course, whatever size of rope is employed it should be capable of carrying the load itself with a considerable margin of ultimate strength. Each rope will have its full share of the load. Thus at no time in its working life will any one rope under this double-rope system be subjected to the same relative stress as it would be in the single-rope system. Furthermore, there will always be a far greater margin of safety. The only extra cost outside the two additional ropes is that required to erect the extra section of framework and the sheaves.

This arrangement is to be tried out at the Wakesiah mine as soon as sinking operations are completed.

METHOD OF WINDING CABLES ON THE DRUM AND A MODEL OF THE ENTIRE APPARATUS

THE OUTPUT OF COAL from the Malayan collieries rose from 101,846 tons in 1916 to 155,279 tons in 1917, and would have shown a greater increase but for the difficulty in obtaining the necessary additions to the plant. There was also some difficulty in obtaining sufficient labor for the mines, due to the greater attraction offered to laborers on rubber estates, where higher wages can be earned with much lighter work.

British Columbia Operators Object to Features of New Act

Representatives of the coal mine operators of British Columbia waited upon the Executive Council of the Provincial Government on Feb. 27 to register some objections to the amendments proposed by Hon. William Sloan, Minister of Mines, at the present session of the legislature, to the Coal Mines Regulation Act.

As is indicated by the summary of these amendments, which already has been published in *Coal Age* (p. 524, issue of Mar. 20), the first change contemplated is the inauguration of a minimum wage board that shall have power to fix districts in which such minimum wage as may be decided upon shall be made to apply. It is not stated, however, that the same wage shall be enforced for each district or that a minimum shall be applied to all the coal-mining sections of the province.

Such legislation, the operators assert, discriminates against the coal-mining industry. They say it also discriminates against collieries, as a minimum may be applied to one and not to the other. It is "vicious," it is declared, for these reasons and because it places too much power in the hands of the Minister of Mines. Further, they maintain that the establishment of a minimum wage will have a tendency to do away with contract work, under which system the coal mines of British Columbia are operated. They would have the effect of reducing production. It will, in their opinion, increase the cost of production and, the greater the cost of local coal, the larger proportion will be imported, and consequently the greater the loss of revenue to the province. The dealers, it is affirmed, were driven out of the coal market of California because of the production costs and, if it was to continue, would meet with a similar fate with regard to all the foreign markets.

Competition, it was declared, was becoming closer in the State of Washington and, when it was remembered that of the 2,000,000 tons produced in 1917 no less than 800,000 tons was exported, the seriousness of such a loss would be better appreciated. Moreover, any greater increase in production costs, which would mean beyond question a further advance in retail prices, would result in the encouragement of the replacement of coal by fuel oil. This transition was a factor which those interested in the coal trade had to face. If it persisted it simply meant that more and more capital which now was invested locally in locally produced fuel would be expended on an imported fuel and would fatten foreign profits.

Exception was taken to the proposal that the Lieutenant-Governor-in-Council should be given power by the Legislature to make such orders as may be deemed necessary from time to time for the further safeguarding of the lives of underground workers. The criticism offered was that it would result in uncertain conditions. Operators might be confronted from time to time with new regulations having the effect of disturbing their smoothly working systems of management.

The delegation took advantage of the opportunity to protest, as well, against the enforcement of the provisions of the Eight-Hour Act, which was passed by the Legislature in 1918, and which gives all those working above the surface around coal mines the same working day as those employed underground—namely, the eight-hour day. This law becomes effective on Mar. 31 next, and it was stated that, as it would tend to increase production costs, the wisdom of permitting it to remain without change should be made the subject of inquiry.

There have been reports that the Provincial Government proposes increasing the tax on coal produced in British Columbia from 10c. to 25c. a ton. While the statement has been publicly made that such action is under consideration, no pronouncement has been made from official circles. It is thought that this accounts for the fact that the operators took occasion, when meeting the Government, to submit a petition for the reduction of the present 10c. a ton tax to 5c. a ton. One of the arguments advanced in this connection was that in Alberta the tax is only 5c. a ton and that British Columbia coal already comes into competition, to some extent, with that of the sister province. It also was asserted that the points already enumerated against any action being taken that would have the effect of increasing costs, which under present conditions were extremely high, applied to the question of taxation. It was essential that the burdens of the operators should not be made greater if the coal-mining industry was to be maintained in a prosperous state.

Fuel Oil and Its Applications

By M. Meredith
Liverpool, England

Apart from its superiority to coal for marine propulsion the use of oil on railways is advantageous in countries that are not favorably situated in respect to coal supply. A typical instance is that of the Mexican Ry., where conversion from coal to oil has resulted in reductions of 32 per cent. in the weight of fuel consumed per train kilometer and of 40 per cent. in the cost of fuel. The oil can be handled from tank cars to storage tanks and thence to locomotives very cheaply as compared to coal. The wastage in handling between shipment and point of consumption (estimated at 8 per cent. to 10 per cent. with coal) is eliminated. No men are required to load up the engine or clean out ashpans. There are no ashpits to empty or ashes to be loaded up and hauled away.

Where used as an auxiliary equipment to coal-fired boilers to meet recurring peak loads the use of oil not only enables the plant to meet sudden and heavy demands, as in the case of electrical power stations, but may obviate the necessity of installing additional boilers with the growth of the average output of current.

The perfect smokeless combustion of oil fuel would prevent or abate the smoke nuisance in closely populated districts. In many instances the local authorities insist on the provisions of smoke legislation being carried out. That much remains to be done in this direction, however, is shown by the statement that in the Administrative County of London 76,000 tons of soot descend every year.

Efficiencies as high as 84.5 per cent. have been obtained on Scotch marine-type boilers using Mexican fuel oil with the pressure system of oil burning.

In the United States a large series of actual working temperature tests have shown that with coal the thermal efficiency of boilers usually varies from 66.6 to 68.1 per cent., with oil from 80.6 to 81.5 per cent.

In Great Britain fuel oil is used in industrial fur-

naces for such processes as billet heating, metal melting, riveting, bolt and nut making, and the manufacture of glass bottles. Of the three systems of burners for oil fuel the pressure jet system, in which the atomizing agent is pump pressure and steam temperature, has been developed during the last 10 years to such an extent that it is now recognized as the most economical system for use under stationary and marine boilers, and is being rapidly developed for locomotive purposes. The oil is drawn from the storage tanks by a steam pump through suction strainers, and delivered through heaters and discharge strainers to the oil fuel burners.

An interesting development is that many metal melting manufacturers have either scrapped their coke-fired furnaces or converted them to gas or oil. The principal metals being thus melted at the present moment are aluminum and what is known as 70/30 brass.

In the early years of this century a French engineer introduced the subject of oil as an auxiliary. The main advantage of auxiliary firing lies in being able to obtain at will a large increase in the power of boilers. The combustion of the petroleum does not in any way prejudicially affect that of coal; in fact, by the introduction of jets of petroleum the condition and efficiency of combustion are improved through a more complete mixture of the gases. It is therefore not correct to consider the evaporative power of coal as identical when passing from ordinary auxiliary firing.

Admitting this as a principle, but supposing the quantity of water evaporated by the coal to be constant, the extra evaporation due to the better mixing of the gases is credited to the petroleum.

In several evaporative trials made on the same boiler of a French naval vessel, when coal alone was burned at the rate of 18.8 lb. per square foot of grate area per hour, the water evaporated per pound was 9.05 lb. With a mixture of coal and 45 per cent. oil, the corresponding figure was 11.34 lb.; with a mixture of the coal and 64 per cent. oil, 14.12 lb. In this last test the efficiency of the mixture was higher than when burning petroleum only.

These tests served as a basis for further experiment, about four years ago, by power station engineers. Their theory was that a poor quality of coal could be conjunction with oil fuel. When used alone the inferior coal tended to cake on the links of the chain grate stokers, thereby retarding the necessary quantity of air from being drawn through the bars to complete

Plant of the West Virginia

THE panorama below affords an excellent view of the Coalton plant of the West Virginia Coal and Coke Co., at Coalton (near Elkins), Roaring Creek District, Randolph County, West Virginia, including a part of the company's batteries of coke ovens. This plant was built in 1901 at a cost of approximately $600,000 and is modern and businesslike in appearance throughout. The coal mined is taken from the Lower Kittaning seam, through two openings, one of which may be seen at the right in the view, the other being hidden by the tipple located immediately behind the coke ovens at the left. The tipple is of steel construction and is equipped with a cross-over dump and shaking screens; four different sizes of coal are prepared at this plant.

Immediately to the right of the tipple is the conveyor, also of steel construction, by which slack is conveyed to the slack bin, which has a capacity of 2000 tons. To the right of the slack bin is the power house, and in the background the blacksmith and repair shop. About at the point where the cloud of steam is seen is

PANORAMIC VIEW OF THE COALTON PLANT OF THE WEST VIRGINIA COAL AND COKE

combustion. The result was a smoldering mass, which traveled slowly along the bars and was dumped into the ashpit as a partly consumed coal. On analysis this ash would probably be found to contain a high percentge of combustible matter. Therefore a much larger quantity of coal was burned per hour to maintain, say, rated evaporation, than would have been necessary had complete combustion been possible.

The theory was that when fuel oil was applied the combustible gases rising from the coal fuel bed were quickly ignited, causing the top of this mass to become incandescent, and thereby tending to aërate the bottom mass, which would allow sufficient air to be drawn through to complete the combustion of the inferior coal.

Sufficient interest was taken in this theory for a large London power station to give sanction for tests to be carried out under a coal-fired Stirling water-tube boiler. One burner was introduced into each side of the boiler approximately 25 per cent. of the distance from the back to the front of the grate, the burners being opposite each other. The oil was stored in an overhead tank capable of holding three or four days' supply. It gravitated to the burners, which were of the steam-jet type, operating with steam as an atomizing agent at a pressure of about 25 lb. per square inch.

The first test was carried out on a coarse slack having a calorific value of 10,400 B.t.u., and a boiler efficiency of 69.25 per cent. was obtained. The temperature of the combustion chamber was 2648 deg. and that of the uptake 660 deg. Fahrenheit.

The final of a series of experimental mixed-burning tests was carried out on a mixture of coarse slack having a calorific value of 10,300 B.t.u. with Mexican fuel oil having a calorific value of 18,750 B.t.u. A boiler efficiency of 74 per cent. was obtained. The temperature of the combustion chamber was 2850 deg. F. and the uptake temperature 628 deg. F. The proportion of oil to coal on a B.t.u. basis was 8 per cent., and on a weight basis 4.96 per cent. The comparative costs were—with coal alone, 2.8; with the mixture mentioned, 2.62, showing a monetary saving of 6 per cent.

The tests showed that with oil at a cost per unit of weight of 2½ times the cost of coal, and burning in the aforementioned percentages, a saving is effected which should induce power station engineers to consider adopting this method of firing in the extremely large power stations of the future.

Coal and Coke Company

located the large electric ventilating fan. In fact the whole plant is operated by electricity and is as nearly fireproof as it can be made. The coal produced at the Coalton plant is used chiefly for steam, coking and domestic purposes.

The company operates 250 coke ovens, arranged in two double blocks, or batteries, and one single block of bank ovens. The latter ovens are almost hidden by the track in the foreground. The remainder of the ovens extend some distance to the left of the tipple. The average capacity of the ovens is 450 tons of coke a day, though as high as 500 tons have been produced in a single day under favorable conditions. To operate the plant to full capacity the services of about 300 men are required.

The town of Coalton is built on the hillside back of the ovens. The company owns 95 houses in this mining village and some sixty of the homes in the community are owned by individual miners. The company is planing the erection of a modern Y. M. C. A. building.

EAR ELKINS, WEST VIRGINIA; THE PLANT WAS BUILT IN 1901 AT A COST OF $600,000

Barking Up the Wrong Tree

By Frank H. Kneeland
Associate Editor, *Coal Age*

SYNOPSIS—*Many men engaged in coal production are inventors—unfortunately, some are patentees. A device may work perfectly, yet a patent covering it may be utterly worthless. In order to be valuable a patent should cover a device that will save a fair percentage of the money previously expended per unit of output. Furthermore, the output affected must be large and the demand therefor must be extensive.*

THE coal industry, probably like all others, is not devoid of a generous sprinkling of inventors and would-be inventors. Ever since *Coal Age* came into existence scarcely a month has passed without someone, somewhere, sending in a patent specification accompanied by a request that it be given publicity. Frequently these missives are little short of the pathetic.

"I will give any responsible party a 49 per cent. interest in this invention, if he will agree to manufacture it and get it on the market." "I don't expect much from this invention, although I am satisfied of its value. All I want is a reasonable compensation for my time and trouble." "Now that I have got this device perfected, I want to get a little something out of it. I will be satisfied with a small percentage on the profit that I am sure will accrue if the thing is properly advertised and pushed." "Please advise me where I can find someone who will be willing to back this invention financially and get it before the public." These are a few of the expressions used by the inventors who write to us.

During the past 20 or 30 years I have, on several occasions, come in contact with inventors, inventions and patents. Naturally, I have gained what has been, to me, more than once, valuable experience.

The Inventive "Bug" Will Invent Anything

The real dyed-in-the-wool inventor, the man who is thoroughly inoculated with the inventing disease, so to speak, of course knows no bound or limit. One of his schemes may deal with an automobile tire, the next with a sewing machine, the next with a steam locomotive, and the next with a telephone; and the pity of it is that all may be equally impractical.

Coming down to the coal industry, what do the patents issued cover? They cover all manner of devices—except the right ones. Mule harness, track devices, car door latches, methods of burning coal, etc., are a few of the schemes that coal men have patented, sending their specifications to *Coal Age* in the hope of obtaining publicity, fame and especially fortune.

And who are the inventors of these devices? They are stable bosses, draftsmen, surveyors, pit bosses, foremen, sub-foremen and under-officials generally. Once in a while an experienced mine superintendent patents some device or other to be used about the mine, while occasionally we receive a communication from an entirely disinterested party; that is, one not directly engaged in coal production. Thus the patent of one of the most practical inventions that we ever received was sent us by a salesman in a retail haberdashery, or some similar emporium.

Now, the objects that men have in making inventions and improvements in existing practice may be both varied and multitudinous. Necessity or expediency beyond a doubt furnishes the inspiration for most inventions. It is easy to conceive that any man confronted with the necessity of performing a certain operation without what he considers the proper means to perform it will develop some scheme for getting the thing done even without proper tools. Then, apparently, the thought comes to him, either from within or without, that this particular operation was never performed in exactly that way before, that it possesses certain advantages and should be patented, Here, as a rule, is where the mistake lies.

Men Take Out Patents for Different Reasons

As a general rule, men take out patents covering their inventions for the purpose of gain—either financial gain or an increase in experience. The ambitious engineer who desires to get into the business of developing either his own or other men's ideas may well seek a patent for no other reason than the acquisition of experience in securing that patent. To him an increase in knowledge is an increase in capital, and a well-developed scheme, even though it be worthless in itself, may be a convincing argument concerning his ability when he seeks to develop the ideas of others. The average individual, on the other hand, usually protects his idea with a patent in the hope of financial gain. Probably 99 per cent. of all patents taken out are of this nature, and it is unfortunate that the person who makes the invention fails to take inventory of what gains are possible before he proceeds to apply for letters patent.

Let us here pause for a moment to consider what is and what is not patentable. Broadly speaking, any new or improved useful idea, process, apparatus or product may be legally patented. Unfortunately, patent office rules and regulations are not absolutely iron-bound, and patents are often issued upon devices that are as old as civilization itself. As an example of this, a patent was issued some years ago covering the use of a corncob for the removal of dirt from various surfaces. Thus, legally, any farmer who picked up a stray corncob in his barn or stable and used it to remove dirt from his horse's legs violated and infringed this patent. Another patent issued from the national capital covered, among other things, "a partially cooked prune as an article of commerce or consumption." Any housewife, chef or other cook who served to his or her family or guests a prune or prunes which were not thoroughly stewed, baked, boiled, fried or otherwise cooked violated this patent. These are, of course, freaks in the patent world, but they illustrate the point.

In not a few instances, also, a man will invent one thing and his attorneys patent something entirely different. Some years ago I had occasion to look up a patent (issued in a country outside of the United States)

which was supposed to cover certain improvements in apparatus for the stocking of coal, ore and similar material. I found that the inventor of the device in question had indeed invented and intended to patent a structure upon which the stocking dump car was to discharge its contents. What his attorneys had actually patented for him was the *stocking* of "coal, ore and similar granular materials."

Because an invention is patentable is by no means a reason that it should be patented. This is of course assuming that the reason for patenting is the hope of financial gain. The patent covering a device which may be perfect mechanically, which may function exactly and fulfill every claim that was made for it, might be an utter failure from the financial standpoint. It is because inventors, after they have perfected their apparatus, do not stop to take stock of what their invention will accomplish, not physically or mechanically, but financially, that so many seek and acquire patents that are not worth the paper upon which they are written.

To again draw an example from my own experience: A few years ago I hit upon a scheme to lessen degradation of coal discharged from rotary mine-car dumps. The idea was simple, comparatively inexpensive, and there appeared to be no reason whatever why it could not be made to work properly and efficiently. A short calculation, however, led me to the conclusion that, although the device was entirely patentable, it would only save a small amount upon each ton of coal handled —not sufficient to pay fixed charges on the device and a bonus, percentage or royalty to the inventor also. I therefore abandoned my first idea of patenting the scheme.

Patent Did Not Make Its Owners Rich

A few years later the scheme which I had devised was patented practically in its entirety by one of the firms manufacturing apparatus for the coal-mining industry, or was patented by an individual and the patent rights acquired by this manufacturer, probably "for and in consideration of the sum of $1 and other valuable considerations." So far as I have ever been able to learn, the holder of this patent has never reaped any large financial returns from it. If he has done so, he is welcome to them, so far as I am concerned, for it was then, and still is, my judgment that large financial gain would not be forthcoming from this invention.

In order that a patent may be of commercial value, the device which it covers must effect a saving in some major operation. A saving in labor or material on a single minor operation that goes to make up any finished product, even though that saving is comparatively large, will not yield the man who employs it any material advantage over his competitor.

Thus, let us suppose that a man has invented a means whereby the dumper on the tipple may operate the car-door lifting device from a point near the dump levers. This device may work perfectly, lift the door of every car without fail, save a large portion of the dumper's time, and eliminate the necessity of his walking from his dump lever to the front end of the car and back again twice every time a carload of coal is discharged. Such a device might be entirely patentable, yet the patent would be of small value financially because it would save only a part of one man's time while that man was engaged on a decidedly minor operation in coal production.

Let us assume, for illustration, that the mine produces 1000 tons of coal per day, and, for the sake of argument, that the device in question saves two-fifths of the entire time of one man whose wages, we will assume, are $5 per day. Now, it will be conceivable that this invention or device saves the operating company $2 per day; but how much does it decrease the cost of coal per ton delivered on the railroad car? Just exactly one-fifth of one cent, which is not enough to give the mining company employing this device any decided advantage over competing coal producers.

Working Out a Typical Case

Let us assume again that a device has been perfected whereby one man loading coal cars in the mine is able to put out twice as much coal in a day as he did before. Let us further assume that the total expense of operating this device amounts to 5c. per ton; also, that the wage rate for mining in the district where this machine is employed amounts to 50c. per ton. It will now be immediately apparent that assuming that the machine operator's wage per day remains the same as the average daily mining wage, this invention effects a radical and decided saving in the cost of coal. The cost has been reduced from 50c. per ton to $\frac{50}{2} + 5$, or 30c. per ton delivered on the mine car. In other words, a saving of 20c. per ton has been effected in the cost of coal, which is enough to give the mine or company employing this device a decided advantage over other mines that do not employ it. A real and measurable saving has been made.

Generally speaking, the conditions under which an invention will be a pronounced financial success are three: The device, process or apparatus invented must make an appreciable saving in the labor, material or other cost per piece or per unit of product, and the present cost, or that entailed without the device in question, per piece of product must be considerable; the demand for the article made must be wide; the number of people engaged in the production of this particular product must be large. If an invention measures up to these three conditions, it should, by all means, be protected by letters patent.

A really valuable idea should not be confided to the protection of one patent alone—it should be protected from all avenues of approach. Most articles may be produced in any one of several ways, and, in order to secure thorough and adequate protection for the inventor's idea, all methods of manufacture, so far as possible, should be protected. It is useless to lock the front door of a stable to keep out a horse thief if the windows and back door are left wide open.

If a person is to follow invention purely and solely from the standpoint of possible profit, it is well to take his inventory of possible results as early in the development of any scheme as possible. If he does not apply the financial test to his invention and trusts only to the mechanical or physical results obtained, and relying on them forges ahead through all obstacles and discouragements until he finally secures his patent from the national capital, he is not only liable but likely to dis-

cover, after he has incurred considerable expense, that he has been after all, figuratively speaking, barking up the wrong tree.

The foregoing has not been written with either the intention or desire of discouraging invention in any way whatsoever. On the contrary, the field for the exercise of inventive and creative ability was never more promising in the history of the world. What I wish to discourage is the idea that any and every new scheme is deserving of patent protection. Patents for automobile tires (so I have been told by a patent office employee whose statement I have no reason to doubt) have been issued in the United States at the rate of about two per day for several years. How many types of such tires are in general use? Are the fingers of more than one hand needed to count them? While this is possibly an extreme case, it shows that probably some thousands of patents have been issued in one particular line of invention, with only a meager few containing real merit.

Probably one of the most frequent errors made by inventors is to think of the industry served by the invention in the aggregate instead of considering a specific case. Take the example of the car-door lifter cited above. The device saves one-fifth cent per ton of coal dumped. The output of the United States is roughly 600 million tons annually. Thus the device, if applied to the entire output, would save yearly 600,000,000 $\times$ \$0.002 = \$1,200,000. Suppose that the inventor is a poor subforeman in a small mine. If he could realize only 1 per cent. of the total saving made possible by his scheme he would consider himself fairly rolling and wallowing in affluence. And having caught a glimpse of the pot of gold at the foot of the rainbow, he promptly proceeds to chase it, regardless of the stern fact that his pet scheme makes an infinitesimal saving in a minor operation in coal production. The golden base of the rainbow is therefore unattainable.

New French Coke-Pulling Device

The accompanying illustrations show an ingenious coke-pulling device, described in a paper presented before a recent meeting of the Societe Technique de L'Industrie du Gaz en France. It is called the Nerriere coke discharger and is recommended especially for use in small plants.

The apparatus consists essentially of two jointed irons carried upon a horizontal piece. At the end of the two irons are two steel hooks which lie against the roof of the horizontal retort and which pivot upon two axes actuated from outside. These two hooks are connected by a steel traversing piece which is withdrawn behind the hooks when the appliance is entering the retort, and then descends behind the coke in order to pull it out.

The form and size of the different parts vary according to the lines or size of the retort. Fig. 1 shows the contrivance as adapted to retorts 10 ft. by 2 ft. 1½ in. by 14 in. The levers for manipulation lock automatically in the positions adapted for entering and withdrawal. During its action the appliance can be fixed so as to make it suit any of the cases shown in Fig. 2, of which the first is the normal condition, the second a case where the roof of the retort has been thickened by carbon deposits and the third shows the condition when the retort has become distorted. In the latter case the iron bars settle down into a suitable position by their own weight.

There is a good deal of flexibility in the apparatus, so that it will adapt itself to retorts varying widely in form and height; it is very strong and substantially built. The supporting rod is suspended in such a way as to allow some play both horizontal and vertical; in this way the appliance can feel its way into the back of the retort, between the coke and the roof. It is

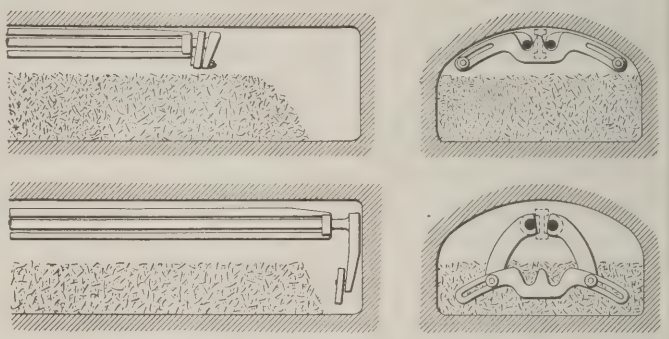


FIG. 1

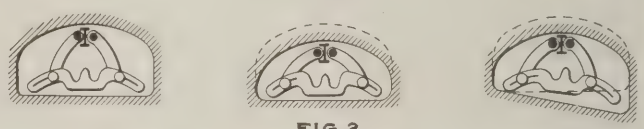

FIG. 2

FIGS. 1 AND 2. DETAILS OF A NEW COKE-PULLING DEVICE

easy, by operating the external levers, to constrict the apparatus and enable it to be withdrawn a little in case any difficulty is encountered in its introduction.

The work required in drawing the coke is greatly reduced with this machine and small men can work it perfectly well; the time taken is also considerably reduced and the coke is brought out with very little breakage. The time taken to put in the extractor and withdraw a charge amounts only to from 30 to 45 sec. From opening the retort to closing it again, the time is reduced from, say, 3½ min. with a good detail of men, or 4 to 5 min. with a less-skilled squad, to 90 to 100 sec. in the former case, and 100 to 115 sec. in the latter case. The whole time for five retorts, including renewal of fuel in the producers, takes 15 minutes.

This appliance has been in use at St. Brieuc, and it has handled very different qualities of coal quite satisfactorily. With large charges the only difference is that the coke has to be pulled with more than one haul.

A SUGGESTION was made recently by one of the large anthracite operators that the percentage of impurities in anthracite be permitted to increase 2 per cent. above the existing standards. If this were carried out, it would mean that 1,500,000 additional tons of slate would be sent to market. To transport this increased amount of impurities to market would require about 40,000 railroad cars, necessitating from two to ten weeks for its delivery. The Bureau of Mines has estimated that the coal mined in the United States, in 1917, had an increase of 5 per cent., as an average, in the amount of ash, taken for the whole country. Also, that this increase in ash content meant an additional loss of 17½ per cent. in the efficiency of the power plant. Furthermore, in some of the mining districts there was a much higher increase in ash than is indicated by this average. As we mined and shipped 544,000,000 tons of coal in 1917, some 27,000,000 tons of this amount was inert material.

THE BOX-CAR LOADER AT THE MODERN MINE AS SEEN BY THE CARTOONIST

Report of Pittsburgh Coal Company for the Year 1918

The year 1918 was a memorable one in the coal business, with its practical immunity from serious strikes and disturbance to the price of coal. Throughout the entire year practically full control of all operations was exercised by the Fuel Administration. The warning of the previous year led to efficient coöperation by producers and consumers under Government regulation everywhere, with the result that there was no time of acute fuel shortage after the severe winter weather of the first quarter of the year. The shortage of coal during the late winter months of 1917-18 was mainly due to transportation difficulties.

The annual report of the Pittsburgh Coal Co. for the year ended Dec. 31, 1918, goes on to say that production had gradually reached full demand by the time the armistice was signed and at prices fixed by the Fuel Administration. These prices were arrived at after a thorough examination had been made as to costs of production; the final price adjustment aimed to stimulate production so as to secure the tonnage required by permitting a reasonable profit to be made in coal mining. After the signing of the armistice business gradually declined. The demand became much reduced, partly by reason of the assurance of customers that their decreased requirements would be readily met. Heavy stocks were taken in and open weather following, a general state of oversupply of bituminous coal developed at the end of the year 1918.

Total Tonnage Below that of Preceding Year

The total tonnage produced by the Pittsburgh company in the year in question was 17,073,283 for all districts. This was a decrease of 915,932 tons under the amount mined by the company in 1917, or 5.36 per cent., and the decrease was practically all in the Pittsburgh district. The number of the Pittsburgh company's mining plants in all regions working all or part of the year were 68; three were leased, two available but idle, and one was consolidated with other workings. General conditions of transportation and labor supply made possible in any event only a 70 per cent. use of the full production capacity of the plants.

Labor supply was reduced throughout the year by reason of a number of employees going into war service, and the efficiency of those remaining was somewhat impaired by the changing of workmen from one position to another. It is to these two causes, chiefly the latter, that a greater tonnage was not realized from the mines. In the first quarter of the year car supply and movement was bad, and in the last quarter the influenza epidemic was severely felt. The report further states that the general condition of the mining plants has been fully maintained notwithstanding labor shortage, the difficulty of obtaining supplies and in the face of a steady demand for a maximum tonnage. However, this was accomplished at a greatly increased cost. One new mining plant was placed in operation during the year and another one is now under construction. No unusual purchases of property or expenditures for construction are in contemplation at present.

During the year 1918 additional coal lands were purchased by the Pittsburgh company. Some 10,085 acres were acquired, principally in the Pittsburgh district. The mining operations of the past year exhausted 2271 acres of the company's coal lands, leaving 186,019 acres of unmined coal on Jan. 1, 1919. Of this territory 154,217 acres are in the Pittsburgh district. Referring to the production figures and the acreage exhausted in the Pittsburgh, Illinois and Hocking districts, we learn that the tonnage mined per acre by the Pittsburgh company was 7747, 5978 and 6283, respectively. It would be interesting to know the average thickness of the seams mined in each of these districts so as to get at the percentage of recovery of coal in each section. In connection with these coal lands, in compliance with the U. S. Revenue Act of 1916, the company appointed three disinterested appraisers to determine the value of such lands. This valuation is exclusive of all improvements and for the purpose of determining a basis for future depletion and taxation. Based on this appraisement $43,886,308 in excess of the amount heretofore carried upon the books of the company is charged to "coal lands and real estate," making a total of $114,225,249 to this account on Dec. 31, 1918. Neglecting real estate and considering the acreage of unmined coal land at the end of 1918, this valuation would give about $614 as the appraisement per acre for the company's coal land.

Activities of Employees' Relief Department

The activities of the Mine Employee's Relief Department have been efficiently kept up during the year under supervision of the advisory board, of which the general manager of mines of the company is chairman. To the support of this department the company has contributed only the expense of general administration since the enactment of the Pennsylvania compensation law. The workmen's compensation fund of the Pittsburgh company now amounts to $878,996 in round figures. There were approximately 3900 personal injury accidents during the past year—an increase of 5 per cent.—all covered by compensation laws; of these 40 were fatalities, or three less than for 1917. The amount paid and adjusted to be paid on account of these accidents amounts to $354,761. Both the company and the employees have been fortunate on the whole in that there was no catastrophic loss of life. Furthermore, the injuries to the workmen were of a lighter average grade than customary. However, the work has demanded a heavy toll even under the safety provisions required by law.

The pension fund of this company now amounts to $212,994.36, of which $189,409.98 is invested in the preferred stock of the Pittsburgh Coal Co. and in United States Government bonds. During the year 1918, 27 names were added to this roll; 17 have died and there are now 110 pensioners. It is natural that this fund should develop a strong bond of mutual interest between the company and its employees. The report states that enlargement of the present pension basis is under consideration. Another activity administered at this company's expense is the Employee's Association. Through this agency the employees have subscribed, paid for and have had delivered to them 5272 shares of preferred and 3476 shares of common stock of the Pittsburgh Coal Co. Moreover, there are now under subscription 9658 shares of preferred and 7303 shares of common stock, or a total of 25,709 shares of both classes. Thus this association has been the means of promoting thrift and of delivering a good investment to the employees on easy terms and at reasonable average cost.

Railroad Fuel Policies Too General Say Coal Operators

In putting into effect the coal policies recently outlined by Director General Hines of the Railroad Administration, instructions have been issued to regional directors which are regarded by coal operators as being entirely too general. These instructions were issued by Henry B. Spencer, who is in charge of the division of purchases of the Railroad Administration. They contain no specific order of procedure. This is regarded by coal producers as necessary to the working out of reforms which are essential to the best interests of all concerned. The Railroad Administration is quick to admit that wages should be maintained at existing levels, but it apparently is reluctant to put into effect conditions which will permit of the operation of the maximum number of mines which furnish employment.

Coal men call attention to the fact that there has been a very gratifying display of good intentions on the part of the Railroad Administration, but the thing most needed just at this time is practical procedure. They are clamoring to know what is meant by "bids." What form are they to take? For what period are they to extend?

Very recent procedure indicates that the price of the lowest bidder is being accepted and then other operators are being called in and offered contracts if they will meet the low man's price. This is held to be entirely contrary to the spirit of the Director General's recent statement. The instructions issued by Mr. Spencer, referred to above, follow in their entirety:

1. The railroads must not violate existing contracts or cancel contracts where the quality of coal is in accordance with specifications, without special consideration by the Central Advisory Purchasing Committee of the reasons for cancelling.

2. The purchasing agent of each individual railroad shall buy the coal for that road under the supervision of the Regional Purchasing Committee of his region. In all requests for bids, the following paragraph should be inserted:

"It is distinctly understood that all bids are to be based on existing rates of pay for all mine labor, and the price will be subject to readjustment in event existing rates of pay are changed."

On contracts awarded or orders placed, the following paragraph should be inserted:

"It is distinctly understood that the prices named herein are based on existing rates of pay for all mine labor and the prices will be subject to readjustment in event existing rates of pay are changed."

3. For coal purchased hereafter, the purchasing agent of each road shall request bids in accordance with paragraph 2. In considering these bids or making recommendations to the Regional Purchasing Committee for contracts, roads must take into consideration the desire of the Director General to make as wide a distribution of the tonnage bought as conditions will permit considering quality, transportation and price, at the same time confining so far as practicable purchases to producers on the individual roads. The purchasing agent should not offer any price to producers and must stipulate that any price named must be based on existing pay for mine labor. He reserves the right to reject any or all bids.

4. The Director General has directed that prices and names of contractors will be available to accredited representatives of the miners or producers who may request the information after contracts are closed. Prices or bids which are not accepted need not be disclosed.

5. Contracts may be made for a period not exceeding one year, subject to cancellation upon 30 days' notice in writing by either party. If in the judgment of the Regional Director it is desirable, the clause requiring 30 days' notice of cancellation may be waived.

6. All contracts for fuel shall contain the following:

"The contractor expressly warrants that he has employed no third person to solicit or obtain this contract in his behalf, or to cause or procure the same to be obtained upon compensation in any way contingent, in whole or in part, upon such procurement; and that he has not paid, or promised to pay to any third person, in consideration of such procurement, or in compensation for such services in connection therewith, any brokerage, commission or percentage upon the amount receivable by him hereunder; and that he has not, in estimating the contract price demanded by him, included any sum by reason of any such brokerage, commission or percentage, and that all monies payable to him hereunder are free from obligation to any other person for services rendered, or supposed to have been rendered, in the procurement of this contract. He further agrees that any breach of this warranty shall constitute adequate cause for the annulment of this contract by the United States, and that the United States may retain to its own use from any sums due or to become due thereunder an amount equal to any brokerage, commission or percentage so paid, or agreed to be paid.

"This agreement of the Director General of Railroads shall not extend beyond the period of Federal Control of Railroads, and unless sooner terminated, shall as to him, terminate at the end of such Federal control."

Fuel Administration Again Urges Consumers to Buy Coal Early

That the public must buy coal early for next winter's needs is urged in an announcement by the Fuel Administration made on Mar. 20. The administration is alarmed at the tremendous decline in production and the accompanying lack of buying. It points out that stocks of coal are rapidly being consumed and that ample provision must be made during the spring and summer, if congestion in coal transportation next fall and distressing shortages are to be avoided.

Urges Continued Governmental Co-operation with Coal Industry

Acting on the assumption that the coal industry is convinced that coöperation with the Government during the war resulted in certain benefits to all concerned, Fuel Administrator Harry A. Garfield suggests that it may be desirable to continue a modified form of co-operation. In order that the views of coal producers may be set forth systematically, Dr. Garfield has requested the National Coal Association to submit the question in referendum form to its membership. The mailing of the proposals to the members of the National Coal Association began Mar. 20. It is believed that practically complete returns will be had by the end of the first week in April. Thus it will be possible to have the consensus of the opinion of the producers of 400,000,000 tons of coal, or three-fourths of the country's annual production. Deductions from the returns will be available for consideration by the directors of the National Coal Association when they meet at Cleveland Apr. 4.

Plan Proposed by Dr. Garfield

In addition to price, the plan goes into various ramifications with the idea of promoting the welfare of all interested. In brief, the plan proposes:

First, that all facts relating to the industry or any question touching it, such as the cost of living, the cost of production, labor conditions, transportation facilities and other factors entering into the cost of coal be officially and accurately ascertained by some of the regular Government agencies, since the Government is the most appropriate representative of the public.

Second, that the public is one of the parties at interest, the other two being capital and labor, and that no action affecting any of the findings of fact be taken until all three parties, through their duly qualified representatives, shall have had an opportunity to consider and discuss the proposals.

Third, that the determination of facts, as outlined, and the formulation of administrative policy are two separate and distinct functions and therefore should not be performed by the same agency of the Government.

Fourth, that the findings of facts, thus proposed, should be submitted to a permanent department or commission of the Government. In this connection it is pointed out that the plan does not contemplate the creation of new agencies, but proposes to utilize existing permanent Governmental organizations.

Fifth, that the President designate some cabinet officer, or other appropriate official, to represent the public in considering any policy proposed, and that as advisers to the commissioner there should be an equal number, say three, of representatives of operators and miners. The function of the commission would be the consideration of all problems affecting the industry, and the formulation of policies to deal with such problems, the commission being a purely advisory body.

Sixth, that the commission shall make recommendations to the President, who would thus be placed in close relation with the industry and all factors entering into it, making for its prosperity or retarding its development.

"Such a plan," says the Fuel Administration, "modified to suit diverse conditions, it is conceivable, might be adopted not only by the coal industry, but by other basic industries of the country as well, in which event the Government would be placed in possession of intimate facts, figures and findings, and recommendations in meeting industrial problems relating to any industry as such problems might arise. It does not conflict with the work now being carried forward by the Industrial Board of the Department of Commerce."

Conference Will Discuss Business Side of Engineering Education

Convinced that insufficient attention is being given to business training in the engineering courses of the higher institutions of learning, the Commissioner of Education of the United States is conferring with representatives of these institutions. In these conferences, the Commissioner of Education is being represented by Dr. G. L. Swiggett, the specialist in charge of commercial education for the Bureau of Education. Dr. Swiggett was the secretary in charge of the second Pan American Scientific Conference, which was held in Washington in 1915.

The matter first was called to the attention of a small group of administrative professors of engineering and commerce from several of the institutions in the Middle West. There was such unanimity of opinion that the average engineer is leaving college with insufficient business training that it was decided to hold a larger conference in Washington Mar. 31. At this conference it is hoped to formulate certain plans as to curricula which it is hoped the various colleges and universities will see fit to adopt.

Since it is expected that the United States will take a far more active interest in projects in other countries calling for engineering skill, it is the opinion of Dr. Swiggett that the requirements for that purpose alone would justify greater attention to the business side of engineering education.

The conference on Mar. 31 also will be attended by representatives of the leading four national engineering societies and of the Society for the Promotion of Engineering Education. The conference is to be of an executive nature.

Coal 44 Per Cent. Higher Than in 1913

Since January, 1913, Pennsylvania white ash coal has advanced 44 per cent., chestnut 42 per cent., and bituminous 44 per cent., according to an article in the March number of the *Monthly Labor Review*, issued by the U. S. Bureau of Labor Statistics of the Department of Labor. The first big jump in the price of all kinds of coal came in the year from Jan. 15, 1917, to Jan. 15, 1918. From Jan. 15, 1918, to Jan. 15, 1919, stove coal increased in price 17 per cent.; chestnut, 16 per cent.; and bituminous, 3 per cent.

A surplus of coal cars throughout the central western region is reported by Hale Holden, regional director for the Railroad Administration.

William B. Symmes, Jr., solicitor of the Fuel Administration, has tendered his resignation to Dr. Garfield. It is effective Mar. 31 and has been accepted. Mr. Symmes will return to the practice of law in New York City.

A study of the prices of coal and coke during the war has been prepared by C. E. Lesher, the geologist in charge of coal statistics for the Fuel Administration. It will be a part of a work on the history of prices of various commodities being prepared by Prof. Leslie C. Mitchell, of the War Industries Board. Mr. Lesher's contribution records the fluctuation in prices of coal and coke from 1913 to 1918. It is accompanied by a large number of diagrams.

EDITORIALS

The Question of Wages

THROUGHOUT the world the economic pot is boiling. It is inconceivable that out of the turmoil no good will come. Already lessons are being learned and great truths are becoming more apparent. In Russia we see the results attending a government controlled by radical socialists. Here in America we are furnished with an example of government ownership in the Federal control of our railroads. We find that the experience of Great Britain is duplicated here, and the railways are run at a big loss. It is also true that the railway deficit has occurred in spite of record receipts.

All of this furnishes food for thought and leads to the conclusion that something is radically wrong. People are commencing to discover that rewards of industry are not fair on the part of either capital or labor when obtained by force. When wages are increased through compulsion, they are nearly always disproportionate to other awards of the same class. There is also a growing feeling that there is a limit to the ability of taxpayers to pay wages that are raised without reason or restraint.

In many industries workmen are maintaining that profits are unnecessary. Only disaster can follow in the wake of such a belief. Profits are the pay of management that produces wages. When profits disappear, work must stop, or wages must be paid by taxpayers.

The time has arrived when employees must acknowledge that when costs are increased above the worth of the product produced, ruin is sure to follow. Nothing is more unsound than the belief that wages and profits are antagonistic, for not only is this untrue, but it is an economic fact that profits and wages always rise and fall together if basic industrial conditions are healthy.

Perhaps the most outstanding truth we have learned is that even excessive wages fail to satisfy those who receive them. There can be neither peace nor industrial progress until both capital and labor learn once for all that justice cannot prevail in a system where either the employer or the employee is permitted to fix his own price in a market controlled by force.

If any one takes you for a sucker and tries to exchange your honest-to-goodness Liberty Bonds for worthless stocks (oil, mine, railroad or other) kindly send the literature he hands you to the Federal Trade Commission at Washington, D. C. The Capital Issues Committee is trying to expose all individuals who are seeking to sell blue sky to the public in exchange for Government securities, and it will appreciate as a patriotic act your assistance in showing the rascals up.

Jacob Is in No Need of a Father

AS WAS said at the recent session of the American Institute of Mining and Metallurgical Engineers, the Governmental control of the anthracite industry proved to the hilt the dangers of Federal regulation. The price of hard coal was made so low that large numbers of substantial operating concerns would have been compelled to close down if the control had continued, unless of course the price set by the Administrator was increased.

The Administrator himself, while not admitting that he had fixed an unjust price to satisfy a grumbling public and to help the persons in power, did admit that the price was too low and that he would have had to raise it himself if the regulation had been continued. Seeing that Dr. H. A. Garfield, like most war controllers, was disposed to be reasonable, his failure to do justice to a large number of anthracite operators exhibits clearly the dangers of Federal control.

Control in general is based on two principles. The first is that the profits made by the least favored of the controlled shall not exceed a certain per cent. This is not a bad feature, and it is one that is openly avowed. The second is a scandalously vicious one, yet every controller seems to believe in it heartily. It is this: Having discovered what price will possibly render a certain profit, let that price be granted; if there are any mistakes, let the industry stand for them.

It appears that the increase in price, when one is granted, is so fixed that it almost always fails to meet increases in cost of operation. The controller is so sternly bound that the controlled shall not make an excessive profit, that he casts out, when he makes the price, all possible contingencies of raise of costs and anticipates all kinds of contingencies that will lessen cost. It is as if an engineer, having made a reasonable estimate, has it reduced, by authority, 10 per cent. instead of having it, as is usual, increased 10 per cent. to cover unforeseen expenditures.

Seeing that large parts of the anthracite industry did not get justice from Dr. Garfield, to whom then could it look? Certainly not to such a body as the Interstate Commerce Commission, which as an organization was rather for closing down the railroads than for providing for their reasonable control. The trouble is that, like Mr. Micawber, it was always looking for "something to turn up." This "something" was expected to relieve the situation without any rise in rates.

The United States Railroad Administration was just as remiss in its sizing up of the situation. It did not reckon on business falling off with the end of the war; it did not consider that the railroads it had taken over had managed to exist solely by letting the roadbeds and equipment deteriorate from day to day; it did not think that the soldier boys would be back looking for jobs. What is the real situation? Business has collapsed and the railroads have no traffic. There are a quarter million more employees than before to be paid, and more are coming from the ranks of the army and navy.

In consequence, the freight rates are found to have been raised an inadequate amount. Nevertheless, when the country's governors and mayors met at a conference recently, they demanded among other things that freight rates be lowered. That was their contribution toward solving the problem—lower freight rates for building and road-making materials.

Control is, and always will be, made on the basis of letting the industry stand for all the mistakes of the estimator. It will be fortunate if that estimator will be wise enough to face half the contingent expenses of production, in spite of public clamor, to say nothing of those which are remote and indeterminable. If he does show such wisdom, however, he will be summarily removed. The public can no more be trusted to set a fair price on the goods it consumes in quantity than a father can be suffered to serve on a jury before which his son is arraigned. The public is an interested party and acts accordingly. No industry in the present state of enlightenment can safely submit its direction to such a court.

Nevertheless, there are rumors that the work of the Fuel Administration is to be perpetuated in the future. The Geological Survey is to take over the statistical work of the defunct Fuel Administration, the Bureau of Mines is to take over the problems of conservation, and it is said it would now like to take over cost accounting, mine inspection and the procurement of clean coal. The Department of Commerce, it is said, is scheduled to allocate and distribute coal and fix the price for it as far as the Administration decides that the price ought to be fixed. The Department of Labor also wants a hand in the regulation, not to speak of the Federal Trade Commission. The coal industry will not lack for stepfathers. It is a husky lad, and one to whom anyone would rejoice to be father, for there is a profit in acting as its common-law guardian.

No profession has a smaller equipment of cost data than the coal-mining profession. The metal-mining fraternity is vastly less reticent than the members of the coal-mining industry, where little has been recorded as to production costs or even as to depreciation and the expenses of construction. The latter, surely, are not forbidden subjects. When will coal-mining engineers be as liberal with their data as are the metal-mining engineers, the civil engineers, contractors and railroad engineers, who have lately done remarkable work in cost accounting?

Financial Backing for the Export Trade

THERE is a growing feeling that the Government must take an active part in supporting the banking interests that are promoting our export trade. Not only is this necessary from a material standpoint, but also for the moral effect it will have. There is further the humanitarian phase in that American capital is a tremendous factor in rehabilitating and restoring the devastated countries of Europe. To be effective this assistance must be of a permanent character; the exporter must feel that his business arrangements are not going to be subject to the periodical changes in the political situation.

One of the first problems confronting the Government will be to provide some means for absorbing the enormous trade balance which this country is piling up in favor of itself. For instance, our January exports amounted to 623 million dollars as compared with only 215 million dollars' worth of imports. Banking authorities are agreed that this is a fundamentally unsound condition, and impossible in normal trade. The coal producer obviously will not be interested in the foreign markets unless he sees definite prospects of something other than credits to be obtained.

It is interesting in this connection to note how the British Government reacted to a feeling of this kind as expressed by the business interests in England a few years ago. The Government immediately established a bank under the name of the Trade Corporation, which was employed to promote and finance business undertakings of any kind in addition to entering into foreign trade itself. This was a radical departure for the old-line banker, who had always been ultra-conservative in the matter of actually entering into trade.

The Corporation so far seems to have confined its activities to financing larger propositions, such as the Portuguese Trade Corporation, whose chief object is to supersede German interests in Portugal. Of more interest, however, to American exporters is the formation of the Anglo-Brazilian Commercial and Agency Co., which the Trade Corporation effected in conjunction with the London and Brazilian bank. The primary purpose of this organization is the promotion and protection of British trade in South America. In Brazilian trade, the Corporation officials complain of a serious trouble, which American exporters have also encountered; namely, the difficulty of obtaining the right kind of men to promote activities in that country.

One of the recognized functions of the Corporation will be its authority to act as a fiscal agent; thus it has already made an industrial issue involving a half a million of debentures to the Morgan Crucible Co., all of which were readily subscribed to. Its activities are of course seriously handicapped by blockade restrictions of various kinds, and the general demoralization in the world's trade, but the Corporation is in no way slowing down in its efforts.

The attitude of the British Government was well summarized in a statement by a prominent Government official made before the British Parliament a number of years ago as follows:

"The Foreign Office and the Colonial Office are chiefly engaged in finding new markets and in defending old ones. The War Office and the Admiralty mostly are occupied in preparing for the defense of these markets and for the protection of our commerce. Therefore, it is not too much to say that commerce is the greatest of all political interests and that that Government deserves most popular approval which does the most to increase our trade and to settle it on a firm foundation."

It is to be sincerely hoped that our own Government will take cognizance of the sentiment expressed in the last sentence of that statement and promulgate a no less helpful attitude toward the prospective exporters in this country. Our exporters must have powerful financial resources behind them to assure their being able to compete on a favorable basis with our British rivals.

Too readily we assume that the eyes of brain workers are vastly inferior to those of manual laborers, and that this explains why so many of the former workers are bespectacled. It may be granted that the brain worker's eyes have, in many cases, been injured by the strain of reading; but much eye trouble is congenital and, as such, will be found equally prevalent among manual laborers and brain workers. Many accidents would be spared doubtless if the mine worker would be morally brave enough not to resent cries of "Four eyes," "Goggle eyes," and "Quatr' Occhi," but wear the spectacles that his imperfect eyes demand. An inquiry is needed into the ocular efficiency of the mine worker.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Those who wait to buy coal are creating an anarchy for which they will undoubtedly have to pay and pay dearly, at least in money, if not in commodities more valuable. The mine workers now laid idle are meditating all kinds of industrial reconstruction, none of their schemes being likely to decrease the cost of coal but rather to increase it. When the public resumes buying, it may find that many fateful things have happened which will make coal a dearer article than they thought. American coal is cheap today because American labor has not demanded European restrictions. But every day makes it more apparent that the American mine worker (or rather the mine worker in America), Canada by no means excepted, looks upon Great Britain's uneconomic labor-union rules as helpful to the workers in the industry. The workman is wrong. European restrictions are suicidal, but who can convince the mine worker of that fact?

Shortness of work has made him advocate the 6-hr. day and 5-day week with wages adjusted so that the day worker in the mines will receive more for 30 hours of work than he did for 48 hours during the war. That is 60 per cent. more per hour or unit of accomplishment. If the day worker in the mines gets it the public will pay 60 per cent. more per ton for his labor, quite a noticeable increase. Secondly, the mine worker is anxious to arrange for the operation of all mines, profitable as well as unprofitable. That will prevent offsetting by economies in production any of the wage increase and working-time decrease now demanded.

PUBLIC WILL PAY DEARLY FOR WAITING

Worse yet, we find the mine worker wanting Government ownership, which is another way of raising costs of production. If the purchaser of coal does not get busy the cost of coal will be raised immensely. The increase just announced by the anthracite operators will be seen to be futilely small, mere playing with conditions, should the mine workers decide to violate their contracts and make the anthracite operator also pay what they are proposing already for the bituminous operators.

The recent adventures in Government ownership have been utter failures. In Great Britain 50 per cent. was added to freight rates and every restriction of accommodation imaginable was put in force. The public was systematically milked by the British Government, but despite this and in spite of coöperation in railroad work such as was highly illegal here before the war, the Government could not make the railroads pay.

In the United States the Government operation of railroads is highly unprofitable. The wage increases do not represent all the increases in operation. There are other increases in operating cost of at least equal size which have arisen largely, though not solely, from Government mismanagement. This is despite the savings resulting from a coöperation which for privately-owned railroads would be a violation of the Sherman law.

In a similar way the nationalization now being discussed by the miners would put a new burden on the public. The delay in reconstruction, the greed of the buyer and his gullibility are about to levy on him a tribute under which he will groan increasingly year by year. We pay dearly for uncertainty. The Peace Conference gets nowhere in Paris, and Bolshevism grows. The buyers of America also get nowhere, fed up by promises of lower prices by the price reductionists, and meanwhile Socialism grows—short hours, nationalization of mines and bigger wages for shorter time. The Republic should wake up for Rome is most certainly burning.

Closing of Mines Causes Trouble

Despite the fact that during the war the miners of Centralia were among the most loyal in the anthracite coal fields, responding to every appeal to support the Government in all war activities, Centralia Colliery has been idle for the past five weeks. The miners and citizens of Centralia, believing that they deserve better treatment, have adopted resolutions as follows:

"Whereas, the Lehigh Valley Coal Co. shut down the Centralia Colliery on Feb. 7, 1919, leaving all the men in the town of Centralia without employment, there being only one colliery in the town for a population of about three thousand of people, and, whereas, during the recent crisis the people of Centralia were as loyal as any in the country; and the town of Centralia sent more men to the army and navy than any other town of its size in the state and the town went over the top with all Liberty Loans and Welfare drives, and, whereas, the miners of Centralia made many sacrifices, working holy days and holidays during the war and during the year 1917, the breaker working 16 hours a day for a period of time, in fact as long as the breaker was in a condition to do so.

UNION CONDEMNS CLOSING UNPROFITABLE MINES

"Therefore, be it resolved that we condemn the action of the Lehigh Valley Coal Co. in closing down the mines of Centralia, leaving the people without employment, as there is no other industry in the town, and also condemn the business men of Centralia for their indifference at this time, an indifference that is inconsistent because in the past they interfered in the troubles of the miner's local, using their influence to get the miners to work whether they got justice or not, and be it further resolved that we request an investigation by the Federal Department of Labor as to the cause of the idleness of these mines of the Lehigh Valley Coal Co."

The grievance committee of the Delaware, Lackawanna & Western R.R., Coal Department, employees, has requested that a speedy effort be made to give all the employees of the Continental and Brisbin Colleries work in other mines. The officials of the company promised to adjust this trouble as soon as possible.

SALARIED MEN MUST LAY OFF AS OFTEN AS REST

The mine workers of the same company complain that salaried men have been permitted to work on days which have been officially declared idle, and thus some men have been receiving more pay than others. The men also request that consideration miners be continued on that basis until an equitable contract can be mutually agreed upon. They urge that an earnest effort be made to secure such an agreement. The officials declare themselves desirous of reaching, without delay, an agreement satisfactory to both employer and employee.

Representatives of the employees also asked that where contract miners have been working on a consideration basis under abnormal conditions they be continued at work on said basis until conditions again become normal. The officials agreed to go along for a period of ninety more days on a consideration basis. Another meeting between the officials and mine workers will be held, at which time it is hoped an amicable adjustment will be made.

Announcement was made on March 18 that the check-off which anthracite miners have sought for years as a concession from the operators will again come up when the two bodies send their representatives to confer on the wage scale for a term of years starting Apr. 1, 1920, which is the date at which the present contract expires.

The check-off, which permits the union to collect its dues at the pay office through deduction from miners' wages, is in effect in many parts of the soft-coal fields, but its introduction into the anthracite region has thus far been resisted by the operators.

Anthracite coal miners are content to let the question of coal prices rest with the federal fuel administration, but they are vitally concerned over maintenance of their present wages, according to a statement given out on Mar. 17 by Thomas Kennedy, president of the Lehigh District, who said that every effort would be put forth to retain the current scale and, if possible, to get concessions improving living and working conditions.

West Virginia Elects Not To Enforce Laws

What amounts to a death blow was dealt the State Police patrol bill in the House of Delegates on Tuesday afternoon, Mar. 18, when, by a vote of 42 to 41, the measure was tabled. Chief opposition to the measure came from the United Mine Workers and other labor organizations and from two state officials—W. S. Hallanan, Tax Commissioner, and S. B. Montgomery, State Labor Commissioner, Republicans, who in alliance with the labor element have fought the bill on political grounds. The police bill as proposed had been endorsed specifically by a number of coal operators' associations, including the Smokeless Coal Operators' Association, whose membership represents a West Virginia production of 35,000,000 tons annually. Governor Cornwell had urged favorable action on the bill as a means of protecting the lives and property of the people of the state from the Bolshevists, anarchists and I. W. W. and within a day or so after his message was sent to the legislature, miners at Wendall in Taylor County after threatening the Governor and legislature with violence attempted to hold a "red-flag" parade as a protest against the enactment of any legislation which would provide police protection to replace that hitherto given by the national guard.

After the Ramage resolution threatening revolution in case the police bill was enacted into law had been adopted by about 20 other miners' unions in the state, F. C. Keeny, President of District 17, U. M. W. of A., issued a statement saying that the Ramage local had no authority to adopt such a resolution because it was an open declaration of violence and as such in conflict with the laws and policies of the United Mine Workers' organization. Federal agents have had the authors of the Ramage resolution under investigation and this prompted Keeney to say that the authors of such a resolution need look for no protection from the national body.

Trouble is expected in several of the districts of the state before the summer is out, not from the native element, but from the foreigners who have become inoculated with Bolshevism.

Illinois Agitates for Shorter Hours

Illinois miners have taken up with acclaim the suggestion of State President Frank Farrington that a demand be made for a 6-hour day and a 5-day week. It is the principal subject of discussion at all the meetings of locals and at all district conventions now being held. The line of reasoning is this: There is not enough work now to give the miners employment more than two or three days a week, therefore the hours of labor should be reduced without reducing the day wage. This would increase the regularity of employment and consequently make the earnings of day men equal to those earned during the war.

The way that the operators will probably solve it will be by the simple and direct method of refusing the demand. They are determined to fight the 6-hour day. They declare that they cannot grant the demand and survive and charge that the 6-hour day is a scheme to bring about Government control if not Government ownership. One item which would add enormously to the expense of production would be the necessity of employing four shifts in the 24 hours of the full day for such laborers as are needed to keep the plant in operation. Of course, this does not apply to the diggers.

The 6-hour day was the principal subject of discussion at the recent convention of Subdistrict No. 7, which was in session three days of the past week at Collinsville, Ill. The principal speaker was John Walker, president of the Illinois Federation of Labor. He and others urged upon the 100 delegates that the only solution of the problem of providing employment for the miners of the district under present conditions is the 6-hour day. Impetus was also given to the coöperative store movement.

The proposition has received some attention at recent joint conferences of operators and union representatives. The latter have been given to understand that the proposed reduction of working hours will not be entertained for a moment, unless the same conditions are enforced in competing states. They have pointed out that the enforcing of such a measure in Illinois would not produce a better condition than at present but on the other hand would make matters worse for the Illinois operators, because it would give the mine workers of other states an advantage over the Illinois mine workers. The union officials have admitted the correctness of this contention.

Short Day Cannot Be Made Locally Effective

President Farrington has even gone so far as to send out a circular letter to the officers and members of District No. 12, who were planning to call a district convention in the interest of the 6-hour day, pointing out to them that such action would be useless, as it would mean that the cost of production in Illinois would be much higher than that of competing districts and would result in little or no work for the Illinois miners. Farrington's letter is as follows:

"Recently a number of resolutions have reached the district office asking that a special district convention be convened to take up the matter of securing a shorter workday.

"As stated in my circular of Feb. 21, I am convinced that we will get no substantial relief until our hours of labor are decreased. Conditions demand a 6-hour work day, 5 days per week, for all the mine workers of the country, with no double shift work on the coal allowed except as necessity may require, and development for increased tonnage should not be regarded as being a necessity. We must wage an aggressive, uncompromising, organized fight to attain that end. Nothing short of that will bring the needed relief. To achieve this reform is vital and paramount and the full strength of our union should be used to attain that end. Other things are secondary, nothing less will do.

"The over-development that obtains in the mining industry of the United States is a waste of capital, of labor and of natural resources, and is an economic crime that would not be tolerated by any other country in the world. The evil of it reaches into the lives and the homes of all of the hundreds of thousands of mine workers in America; it is ever present to make impossible their security, to blight their happiness and to prevent their prosperity. It is so fundamentally wrong that justice demands its correction. No make-shift expedient devised to carry us through the period of reconstruction will do. The remedy must be lasting and true.

Two Hours Cannot Be Taken Out of Profits

"However, the matter of securing a shorter workday is too big and too far-reaching in effect to be disposed of by action of a district convention. It must be obvious to all that a district convention could not secure a shorter workday for all the mine workers of the country and that it would be useless to attempt to shorten the hours of labor in Illinois without regard to the hours worked by mine workers elsewhere, as to do so with the present over-development in the mining industry would mean, should we succeed, that the cost of production in Illinois would be so much higher than that of competing districts that Illinois coal could not be marketed and we would get little, if any, work at all. Thus it is that the matter is not one to be handled by a district convention. But you may be certain

that the matter will have attention and that a definite line of action will be devised when your policy committee, which is to assemble at President Hayes' request, meets in Indianapolis on Mar. 18."

The Fifth District, in convention at Taylorville, Ill., adopted a resolution in favor of organizing a labor party. The 6-hour day and 5-day week were approved. The anti-injunction and the state constabulary bills were denounced and officers and members were urged to work for their defeat.

The policy committee of the United Mine Workers assembled at Indianapolis, Ind., has accepted the 6-hour day and added thereto the 5-day-week, an increase in tonnage rates, day wages, deadwork and yardage and nationalization of mines. The increases to be demanded were at last advices still being discussed.

British Miners Threaten Strike

While there is perhaps not the same organic unity in Great Britain among the miners that there is in America, there is a unity of aims, and, what is more, there is a triple alliance of mine workers, railroad and transport workers, an organization formed to make the taxpayers who do not belong to this widely extended union pay them an unreasonable wage and grant them unusual privileges. If that concession is not granted, England and Scotland will sit still and starve.

It is not therefore a comfortable situation in which the taxpayers of Great Britain find themselves. The people must conciliate the Mighty Three or many persons will starve to death. Some years ago there was a big strike of this kind and some people not interested at all in it starved rather than ask for alms. This threatened strike may not come off. It is said that the Government "for the first time shows an inclination to meet the miners and railway men fairly instead of haggling over each point." That is to say, the Government is weakening under pressure. It is going to desert the unmarshaled majority for the marshaled minority.

The trouble started long ago. It is hard to set a date, for the mine workers and railroad men have been chronically discontent. They had a grievance which would stand some inspection. During the stress of war wages had gone up a little less than cost of living—the difference was pitifully small as a basis for a national strike, only 115 per cent. increase in cost of living against an advance of 106 per cent. in wages. The Government was perfectly willing, as were also the operators, to grant that, or even a larger increase than any that the increased cost of living made reasonable.

The miners first voted that they would stop work on Mar. 15, a ballot being sent out to the different districts of the Miners' Federation. In order to expedite matters, the Executive decided that each district print the necessary ballot papers. Speedy taking and counting of the vote was necessary. The union figured that haste would express determination and paralyze those who would otherwise oppose the attempt to shut down British industry or impose on the taxpayers an unequal burden in favor of the Mighty Three. The ballot-paper was quite simple in form and was as follows:

MINERS' FEDERATION OF GREAT BRITAIN.

Ballot of Members.

1. Application for 30 per cent. increase in wages.
2. Six hours day.
3. Full maintenance at trade union rates of wages for miners unemployed through demobilization.
4. Nationalization of mines.

The Government having failed to grant any of the above proposals, Are you in favor of a National Strike to secure them?

Yes.....

No.....

Please place an X opposite Yes or No in the space provided for the purpose.

Frank Hodges, Secretary

In their deliberations at the Southport Conference the Executives were not satisfied merely to recommend the ballot. In their resolution they said, "We further strongly urge all members to vote in favor of a national stoppage until our demands are conceded."

The vote favored a strike and great was the consternation which followed. Never in living memory had local stocks been so small. When the strike was approved by vote Londoners were forming queues to purchase 50-lb. bags of coal with which to mitigate as best they could the bleak coldness of their homes. True, spring was near at hand and the householder could rely on the sun not to join the Triple Alliance, but even this was no consideration at all to those workers who were dependent on the coal for their livelihood.

The decision of the miners was followed by the railroad men and transport workers. Even since 1914 they have planned a concerted attack on those who were not employed with them in their industry, but the war delayed matters. There were even bigger things on hand. Now that the war is over the program is again taken up.

A Coal Commission was formed some time ago to find out a solution. The majority of the commission has found one and has returned an interim report of date Mar. 20. The operators were making too much money according to the findings. Possibly the commission was right in this contention, as the Government is still proposing to let the operator make a profit of 28c. a long ton or 25c. a short ton. The Government, according to Bonar Law's statement in the House of Commons, will reduce the operators' profits 13,000,000 pounds or $65,000,000 per year.

But that will not pay the increase in wages proposed during the current year, which is 43,000,000 pounds or $215,000,000 a year. The balance of 30,000,000 pounds or $150,000,000 will apparently come out of the pockets of the taxpayers. But they need not worry about that, for in 1921 it will be much more. Just as the Government of Great Britain has bought dear wheat in the United States and sold it cheap at home at the loss of the taxpayer, so it will by subsidy or purchase put up wages and yet keep down the price of coal.

It must not be considered that the Sankey Commission, so called because Justice Sir John Sankey is chairman, was unanimous. There were three reports. The principal one recommended that underground the hours of work should be limited to seven, instead of eight. This provision would come into effect July 16 of this year. On July 13, 1921, the duration of underground work would be reduced to six hours, if the economic position of the industry warranted it. Bonar Law in the House of Commons explained this, saying that in 1913 the output was 287,000,000 long tons. It was expected that it would be possible by July, 1921, to get the same tonnage, working only two-thirds of the time.

The wage increase proposed is not large, being two shillings, or 48.7c., per shift for those colliery workers now under sliding scales and an advance of one shilling, or 24.35c., per shift for workers under 16 years. The committee favored giving the mine workers an effective voice in the direction of the mines. The present system of ownership and the existing manner of operation is condemned, and the commission advocates some substitute, either nationalization or unification by national purchase and joint control. The report declares that one penny, or 2c., per long ton should be collected at once on all coal brought to the surface. This penny is to form a housing fund for improving the dwellings in the colliery districts. It seems a small amount, but it will bring in about a million pounds, or five million dollars, annually.

Sankey's report is signed by Arthur J. Balfour, Sir Arthur Duckham, Director of Aircraft Production, and Sir Thomas Royden, member of the Shipping Control Committee. It seems to concede everything within the scope of the imagination, but it does not please the miners' representatives led by Robert Smillie, who is the miners' leader; Frank Hedges, Sir Leo Chiozza Money, Sidney Webb and others who in their report recommend acceptance of the miners' demands in full, including nationalization of mines. The miners, it may be recalled, ask for a 30 per cent. increase. The operators' representatives favored a 36c. advance per shift and a 7-hour day.

DISCUSSION BY READERS

EDITED BY JAMES T. BEARD

Utilizing Mine Gas to Save Fuel

Letter No. 2—I was very much interested in the letter of W. D. Owens, *Coal Age*, Feb. 20, p. 372, which was reproduced, a little later, in the Wilkes-Barre Record, one of the leading newspapers in the upper anthracite valley. Mr. Owens' article related to the utilization of methane gas for steam-raising purposes, and was based on the recent experiments that have been taking place at the Loomis colliery of the Delaware, Lackawanna & Western Coal Co., near Wilkes-Barre.

Every new venture will surely bring its difficulties, which require careful study and watchfulness to overcome. But let us hope that none of the dangers to which Mr. Owens has drawn attention will ever be realized in the undertaking now at hand. As in many other large enterprises—the Panama Canal or the New York Subway, for instance—so here man's ingenuity will eventually prove successful and master the problem of utilizing the great power now lying dormant in the waste gases of mines.

Speaking of the experiments and tests that are being made in the Loomis colliery, it can be stated with certainty that the mine management are running no risks of blowing up the plant or causing an explosion within the mine. Whether these tests will prove successful or not, the results obtained will surely add to our knowledge regarding the handling and the possibility of utilizing this most important of the mine gases.

CALCULATING THE HORSEPOWER OF THE WASTE GAS
